Annual budgets for enforcement of anti-smoke ordinances are, as Dr. Hood said, small, variable, and uncertain. St. Louis, with its new ordinance, is at the moment at the top among cities with more than 500,000 population, with an appropriation equivalent to nearly 5 cents per capita. Hudson County is next with 4 cents per capita. Then come, in order, Chicago and Washington with about 2½ cents each; Boston and Pittsburgh, each with a little less than 2 cents; Cleveland and Baltimore with 1 cent each; and Detroit with 6/10 cent.

Obviously, with such small enforcement staffs and meager budgets, anything like real supervision is impossible. As a matter of fact, the records of a bureau under such handicaps give an erroneous idea of actual conditions.

It has been possible, during the last several years, to make good use of WPA funds to secure a great deal more information than could be gotten routinely. Here is a part of the results obtained in Pittsburgh with a corps of

50 WPA observers as compared with those of the three city inspectors.

Pittsburgh has about 5,000 stacks regulated by the anti-smoke ordinance. In the exempt class there are 154,000 dwelling units, in 114,000 of which solid fuel is used. The city was divided into 50 districts and a WPA observer, after being taught to differentiate between dense smoke, medium smoke, and light smoke, was assigned to each district. He averaged 120 hours of work per month, and during about two-thirds of the time was on duty from 7 A.M. to 1 P.M., on Mondays to Fridays, and the remainder of the time his shift was from 12 M. to 6 P.M. He was expected to report time, character of building, density and duration of smoke. While even with 50 observers only a percentage of the total number of stacks was under observation at any time, the vastly closer supervision was by comparison much better than an arithmetic ratio. A summary is given in Table I for the month of March, 1938. During that month the three city smoke inspectors reported 62 violations on all classes of stacks except domestic, which are exempt from regulation.

PRODUCTS OF COMBUSTION OTHER THAN VISIBLE SMOKE

Thirty-nine of the 80 cities previously referred to have some sort of provision against excessive fly ash, fumes and/or noxious gases. Of this number, 8 apparently have regulations to cover fly ash at least; 6 require screens at the top of the stack, probably intended for rubbish incinerators; the rest either do

not specify, or they say there is no provision for enforcement.

Dust separating equipment is readily available for large and medium size plants, but these in number are a small percentage of the total. Something inexpensive and relatively efficient must be developed for the myriad of small plants. As regards sulfur compounds, there is at present no practicable method of elimination except for the largest plants. Other gases and fumes from industrial processes present other problems.

Standards of permissible dustiness or permissible noxious or obnoxious gas content of stack gases are lacking, although this problem is receiving serious study. There is also the technical and time-consuming task of sampling and analysis to determine compliance or violation which, obviously, cannot be done by smoke abatement bureaus as today constituted and manned.

PRACTICAL PROCEDURES

Requirement No. 1 for whatever success is possible, is coöperation between the bureau and the various groups with which it must deal—Coöperation with a capital "C." These groups include (1) the owners and operators of fuel burning plants, from the power plant having boilers rated in thousands of horsepower to the boiler or furnace which supplies heat for a small space; (2) manufacturers and salesmen of equipment—furnaces, boilers, stokers; (3) producers and distributors of fuel; (4) architects and engineers concerned with design and installation of plants;

TABLE I

Number of "Smokes" Reported by 50 WPA Observers

	<i>Heavy Industries</i>	<i>Light Industries</i>	<i>Commercial and Heating Plants</i>	<i>Domestic</i>
Light Smoke	586	2,215	9,590	83,698
Medium Smoke	596	1,601	5,771	28,478
Dense Smoke	436	1,263	4,299	15,317

and (5) civic bodies, the press, and the general public.

CODE OF REGULATIONS

The bureau has rules and regulations to guide those selling, or those purchasing, installing, and using fuel burning equipment. These rules and regulations are limited legally by the limits set in the ordinance. The enforcement officer will of course see that new installations and those receiving major repairs conform to those requirements.

In formulating a code, there are some excellent guides. Much of the material can be taken as prepared by national organizations, or as used in comparable cities; much can be taken from commercial catalogs. However, attention must always be given to local factors, peculiar to any community, as wind velocity, topography, fuels commonly used, etc. These may make it advisable to increase the requirements for a particular city, or even for a part of that city.

Proper capacity—boiler, firebox and combustion chamber, stoker, breeching, stack—and appropriate fuel must be insisted upon from the standpoint of operation in conformity with the ordinance. A sense of false economy may and often does prompt the purchase of equipment which, while it may give the necessary output, must over a large part of the time be forced, resulting in an excess of smoke.

Allowable output, stoker setting heights, and stack sizes will be subjects of occasional argument, where the city's requirements differ from catalog recommendations. On the other hand, the enforcement officer knows whether there are local conditions that influenced him in setting up his standards. Aside from such local conditions, those standards are, or should be set up on the basis of consideration of the type of operation to be expected, rather than

what can be done in a supervised test. Then, too, the enforcement officer cannot differentiate between makes of the same type of equipment, if all can meet his requirements in normal operation.

FIELD OBSERVATION AND INSPECTION

Since it is physically impossible for the present small number of inspectors to keep in desirably close touch with all plants, there develops a differential treatment. Some plants need frequent attention, others require very little. During the heating season the work of the bureau is multiplied. Hand-fired heating plants and many heating plants that are stokered require closer supervision than do most high-pressure installations. A large percentage of the firemen in medium size and small heating plants have other duties to perform. Fires are not given proper attention, and many such firemen know too little about firing a boiler, or furnace. Result, much too much smoke.

An important part of the field work is the handling of complaints. Some of these have real bases and the bureau is glad to have this outside assistance. Many complaints, however, are about cinder and ash rather than visible smoke; some are against odors; while many are the result of personal animus against neighbors. But, some of the complaints are justified, therefore all must be investigated.

COÖPERATION THE MOST IMPORTANT FACTOR

To return to the matter of coöperation, without which the enforcement of an anti-smoke ordinance would be extremely difficult, if not impossible.

Owners and Operators—Members of this group are, on the whole, very coöperative. They are willing to do what the city bureau requires, although at times it involves spending more than was anticipated for a new plant, replacing grates with stokers, or for

changing fuel. Of course there are inevitable exceptions where argument or even an ultimatum may be necessary, but such cases are relatively few.

Equipment Manufacturers and Salesmen—The city's requirements must, of course, be made known to the members of this group, and only borderline cases need to be discussed. The enforcement officer must not play favorites; and if a concession is asked for and made in a particular difficult case, all bidders on that job should be notified and allowed the same concession. In every way, all who are making or selling approved equipment must be treated alike. There will then be no question about coöperation.

Producers and Distributors of Fuel—It is important that the enforcement officer have a knowledge of the fuel situation, particularly with reference to processed fuels. Many distributors maintain corps of engineers who will work with the city bureau in solving difficult or aggravating problems that involve determination of the best type or grade of fuel for particular plants.

Architects and Engineers—These are concerned mostly with new buildings and plants. Obviously, the possibility of trouble can be avoided if the bureau of smoke regulation passes upon plans before the building permit is issued, so that proper boiler room arrangement and stack may be assured. I believe this is now the general practice and is welcomed by the architects and engineers.

Civic Bodies—Chambers of commerce and civic clubs usually have smoke abatement committees and endeavor to aid the enforcement officer in his task. The bureau should be represented on all such committees, so that committee-men may be kept informed.

The Press—The local newspapers are keenly interested in air pollution. They can be, and usually are, a powerful factor in keeping the subject in its

proper light before the public. This is especially true during the occasional periods in the fall and winter when, in moist air and with little or no wind, the people are sniffing, sneezing, and coughing in the smog.

The General Public—The apathy of the public toward this important matter of air purification is the principal reason progress has not been more rapid and more complete. In each community there is a small minority of interested persons, but the average individual pays no attention unless a neighbor showers him with soot, or until his city has a two or three day smog. He is then vociferous and wants immediate and drastic action. Usually the blame for smoke is laid at the doors of industry—the mills and the railroads. It is true that an increasing number of householders are asking what to do in their own homes, but the increase is too slow to be of early benefit in changing conditions in a city.

It might be of interest here to say that, last spring, 100,000 copies of a questionnaire titled "Smog and You," were sent out by the Pittsburgh Department of Public Health, acting in coöperation with the Allegheny County Medical Society, Air Hygiene Foundation, Mellon Institute, and other scientific organizations. In reply to one of the many questions: "How do you feel during 'smoggy' days?" 53 per cent of those answering reported stuffed-up nose; 62 per cent had a rawness or a tickling in the throat; 25 per cent increased coughing; 22 per cent increased sinus trouble; and 9 per cent reported feeling "as usual."

CAN SUCCESS BE ATTAINED?

I have stated briefly some of the limitations of present-day smoke abatement, and indicated sketchily what is involved in enforcement of an anti-smoke ordinance.

The question that arises naturally,

though not included in the title of this paper, is: "What can be done about it?" My answer is that it is now possible, from an engineering standpoint, to provide means for a marked advance in the prevention of air pollution. Any urban community can secure the benefits of hygienically pure and relatively nuisance-free air if and when it wants it and each individual is willing to assume his very small part of the burden.

Without a detailed discussion, I should like to close with the following statements:

Ordinances specify limits for smoke, Fuel-burning equipment need not now be designed to do more than meet those limits although much of it does.

While current regulations must be made in consideration of equipment and fuels currently available, there is no reason against the formulation of ordinances that shall be progressively stringent, with limits narrowing at specified future dates. The engineering profession is accustomed to meeting such challenges.

In considering conditions in a city, the fuel burning plants may be divided into three major groups (we are not here considering industrial dusts, fumes and gases, nor air hygiene as it is affected by pollutants other than those from the combustion of fuel):

1. Large plants having continuous engineering supervision and operated according to best practice can and usually do work well below prescribed smoke limits. Such plants could and would meet requirements more stringent than are now in effect in most cities.

2. An intermediate group includes smaller industrial and commercial plants, institutions, and the heating plants other than those in private homes and small apartment buildings. Many of these are stoked, a large percentage of the stokers being of the intermittently operating type; many are fired by hand. The human element is a large factor. Many of the firemen are inexperienced, and many have other duties than the care of the boiler plant.

3. The domestic heating plant fired, improperly more often than not, by the householder, the housewife, or the maid, is the most troublesome because of the great number, and because of the impracticability of education en masse.

If and when a community wants cleaner air and is willing to assume the obligation involved, a radical change in the ordinance might confidently place more restrictive limits on group 1. As to groups 2 and 3, it is my opinion that adequate results will be secured only if the ordinance restricts the use of potentially smoky fuel to equipment that will burn such fuel smokelessly under the ordinary conditions of operation; and, where the plant—be it industrial, commercial or domestic—is not so equipped, requires the use of a fuel that cannot smoke.

Use of Agar Slants in Determining the Sanitary Quality of Milk*

G. J. HUCKER, PH.D., F.A.P.H.A., AND W. C. HAYNES

Department of Bacteriology, New York State Agricultural Experiment Station, Geneva, N. Y.

THE growing tendency among those interested in determining the sanitary quality of milk to place more emphasis on relative rather than actual numbers of bacteria present gradually places new interpretations on older methods of enumerating bacteria. Methods which do not meet the requirements of accuracy in so far as counts are concerned become of importance if they are of value in making comparative determinations of the number of bacteria present. One of the most important methods of this type is the smear culture method commonly referred to as the Burri agar slant procedure.

It is not the object of this discussion to present the agar slope method as a new or particularly accurate method for determining the number of bacteria in milk but rather to emphasize its value as a method of determining the relative numbers of bacteria in samples of milk as well as its use for the control of certain plant procedures in processing milk and dairy products.

HISTORY

The agar slope method was originally described by Burri¹ as a method of enumerating bacteria in milk. The inaccuracies of the method as a counting procedure were soon recognized, and the method has failed to gain wide recognition as a counting method in comparison with the direct microscopic and Petri plate procedures. Later, Dorner² used the agar slope procedure in determining the number of bacteria present in freshly drawn samples of milk and reported it as most useful under such conditions. He also found that the agar slope method gave higher counts than the more commonly used standard Petri plate procedure. Several other investigators have used the Burri slant procedure^{3, 4} in various investigations, more particularly mastitis and milk plant studies. Recently Long and Hammer⁵ have presented results which indicate that the Burri slant procedure has value as a means of determining the number of organisms in various parts of masses of butter.

TECHNIC

The procedure which was originally described by Burri has not been changed materially during the period since it was first described. It consists of the preparation of the agar slopes of any

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938. Approved by the Director of the New York State Agricultural Experiment Station for publication as Journal Paper No. 308, January 10, 1939.

desired composition with the provision that 2 per cent of agar be used in order that the agar may be sufficiently firm to allow surface streaking. Each tube is filled with from 6 to 8 cc. of the agar and inclined to obtain a slant about 3 inches in length. Before use, the tubes are allowed to remain for a sufficient time in a horizontal position to dry the surface of the agar thoroughly.

A standardized loop is used for measuring the amount of milk which is to be transferred to the surface of the slant. This loop is made of platinum wire 0.3 mm. in diameter and the loop so constructed as to be 1 mm. in diameter. This loop will transfer approximately .001 cc. of milk.

The loop of milk taken from the sample to be tested is touched lightly at various points from the bottom of the slant to the top, followed by a transverse streaking from the bottom to the top of the slant in order to distribute the deposited milk evenly. In removing the milk from the sample to be tested it is advisable not to insert the loop more than 2 to 3 mm. into the milk. If the loop is passed into the sample to be tested for greater distance, inaccuracies will occur because milk adheres to the stem of the loop.

DATA

One of the principal considerations in evaluating the use and accuracy of any procedure, and in this case the Burri slant technic, is a comparison

with the standard agar plate procedure which, although it is known to be inaccurate, is generally accepted as a basis for such comparisons.

Where the two procedures were compared using the same medium and temperature of incubation, it was found (Table I) that of 387 samples, 106 gave higher counts on agar plates than with Burri slants, while in 281 of the cases the count was higher on the Burri slants than on the Petri plates. A closer analysis of these results indicates that the percentage of instances in which the higher or lower counts occurred on Burri slants was not affected by the number of organisms in the original sample of milk until the number of bacteria present produced overcrowded conditions on the Petri plates. From these results it is evident that over a series of samples the Burri slant technic as a procedure will generally give higher counts than the Petri plate method, a finding which confirms the conclusions reached by Dorner.²

Burri slants are of special value when determining the presence of streptococci in samples of freshly drawn milk. In a study of 4,675 samples (Table II) of freshly drawn milk in which streptococci were not demonstrated by the Burri slant procedure, it was found that in only one of these instances were organisms evident when the sample was examined by the direct microscopic method. However, where the samples were incubated before they were examined microscopically, 55 were found

TABLE I
Relation of Burri Slants to Plate Counts
Standard Agar Plates Incubated at 37° C. for 48 Hrs.

<i>Number of Instances Where the Count Found on Burri Slants was in the Range Indicated</i>		<i>Number of Instances on Agar Plates Where there Was</i>	
		<i>an Equal or Greater Number of Colonies Than on Burri Slants</i>	<i>a Smaller Number of Colonies than on Burri Slants</i>
1,000 to 10,000	299	91	208
10,000 to 100,000	74	15	59
100,000 plus	14	..	14

TABLE II

The Detection of Streptococci in Freshly Drawn Milk on Burri Slants, and by Direct Microscopic Examination Before and After Incubation

Number of Samples	Burri Slants		Direct Microscopic Examination of Unincubated Milk		Microscopic Examination of Incubated Sample	
	Streptococci Not Observed	Streptococci Observed	Streptococci Not Observed	Streptococci Observed	Streptococci Not Observed	Streptococci Observed
4,675	4,675	0	4,674	1	4,620	55
1,372	0	1,372	1,354	18	246	1,126

in which long chain streptococci were present although none were evident on the Burri slants. The microscopic examination of incubated freshly drawn milk is one of the best procedures to demonstrate the presence of long chain streptococci. However, these figures make it evident that the Burri slant procedure is for practical purposes as accurate for use in determining the presence of long chain streptococci in freshly drawn samples as microscopic examination of the samples subsequent to incubation. At the same time, colonies are available for isolation and subsequent study.

In a study of 1,372 samples in which streptococci were observed by the Burri slant procedure, it is of interest to note that all except 18 of these samples failed to show long chain streptococci when examined by the direct microscopic procedure. However, when these same samples were incubated before microscopic examination, long chain streptococci were demonstrated in over 80 per cent of the samples. These results again indicate the surprising accuracy of the Burri slant procedure as a means of demonstrating the presence of long chain streptococci in freshly drawn milk.

DISCUSSION

The Burri slant procedure is not a method which should be considered as a substitute for either the Petri plate or the direct microscopic procedure. However, it does have, because of its simplicity and the possibility of isolating

cultures, certain advantages not found in either of the above commonly used procedures. The Burri slant method is of particular value as a means of finding and isolating the long chain streptococci that occur in freshly drawn samples of milk. The procedure may be employed with excellent results as a means of quickly finding the infected udder or quarter involved in septic sore throat or other epidemics. The amount of apparatus required is small and inexpensive (largely culture tubes) and within 30 hours streptococcus colonies are easily discernible on the agar slope. These can be removed for further study. It has a distinct advantage for this work over the Petri plate method because of the limited equipment necessary and over the direct microscopic procedure because it is possible to isolate suspicious colonies.

The Burri slant procedure also is of special value for commercial dairies and food processing establishments for use in finding sources of bacteria that may contaminate the milk or food during processing. The limited amount of equipment again allows its use in the plant and the examination of a large number of samples taken throughout the processing operation.

It is also of particular value for determining the possible cause of food suspected epidemics. In those cases where a large number of sources of offending organisms must be examined, samples can generally be secured during the field investigation and immediately inoculated onto the agar

FIGURE I—BURRI SLANTS PREPARED FROM FRESHLY DRAWN MILK
A and B show a predominance of *Streptococcus* colonies; C and D show only *Micrococcus* colonies. In the latter case, the colonies may be either white, yellow, or orange, depending upon the type of *Micrococcus* present.

slopes for subsequent incubation and observation.

There are certain difficulties involved in the use of the Burri slant procedure which should be recognized. Although much more accurate than heretofore supposed, it cannot be considered, because of the rough method of measuring the amount used in the inoculation, as having great accuracy as a method of estimating the number of bacteria present.

One of the chief difficulties with the Burri slant procedure is a tendency for those who are using it in a routine manner, to place undue value on the appearance of the colonies on the slope as a means of determining the type of organisms present. In many instances, particularly where slants are crowded, the appearance of the colony is entirely different on the agar slope from the colony of the same organism where only a few bacteria are present or on agar plates. In many instances colonies of micrococci on overcrowded Burri slants will have the same characteristics

as colonies of streptococci, and may easily be so recorded.

CONCLUSIONS

The Burri slant procedure is suggested as a surprisingly simple and accurate method of estimating the number of organisms present in various substances and its availability for use in detecting sources of contamination is discussed. It is not suggested as a method for accurate counting of the number of organisms present, but it is shown to have practical value for use in controlling the sanitary quality of milk and other products.

Public Health Engineering and Sanitation Service in a Rural-Urban Area*

WILLIAM T. INGRAM

*Sanitary Engineer, San Joaquin Local Health District,
Stockton, Calif.*

THE writer has chosen to approach this topic from the standpoint of a personal experience rather than from that of an academic discussion. In this paper it is proposed to define and describe the characteristics of the San Joaquin Local Health District.

The county is located centrally in California at the head of the San Joaquin Delta approximately 60 miles east of San Francisco. It extends eastward to the foothills of the Sierra Nevada Mountains and southwest to the Coast Range. Three streams, the Mokelumne, the Calaveras, and the Stanislaus, drain from the Sierras and discharge into the San Joaquin River in the Delta area. There are some 700,000 acres of rich agricultural land, growing such products as grapes, peaches, cherries, apricots, walnuts, almonds, tomatoes, asparagus, celery, peas, potatoes, rice, sugar beets, and grain. The abundance of water provides pasturage for many herds of dairy cattle.

Ocean-going vessels and three trans-continental railroads provide world-wide transportation facilities. Seven hun-

dred miles of paved roads in the county and direct highway connections with San Francisco and cities throughout the San Joaquin and Sacramento Valleys provide excellent intrastate transportation.

The county has a population estimated at 121,000. The City of Stockton, the county seat, has a population of 56,500 and 3 other cities in the county aggregate a population of 16,000. The rural population is 48,500 or 40 per cent of the total population.

It may be asked what bearing these characteristics have on sanitation and engineering. It is the purpose of this paper to illustrate that question and, in so doing, to develop the organization and functions of the Sanitary Division of the Local Health District.

Prior to 1923, each city had its own health department. In that year the Health District, comprising all of San Joaquin County, both incorporated and unincorporated, assumed the task of health service. The act¹ under which the District was formed is quite liberal, as can be determined from a few excerpts:

Each Health District shall have and exercise the following powers . . . to acquire, construct, maintain and operate all works and equipment necessary for the inspection of

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

water, milk, meat and other foods, the extermination of rodents, and the disposal of garbage and waste . . .

To enforce all statutes relating to public health . . . and all orders, quarantine regulations and rules presented by the State Board of Health . . .

To enforce such local orders and ordinances pertaining to health and sanitary matters within the District as may be authorized by the appropriate local authorities . . .

To exercise all needful powers for the preservation of the health of the inhabitants of the district, whether such powers are herein expressly enumerated or not . . .

This grant of power is to be liberally construed for the purpose of securing the well-being of the inhabitants of the District.

The Board of Trustees consists of a representative appointed from each of the 4 cities and one from the rural area of the county. At the present time, a doctor of medicine, two dentists, an engineer, and a farmer are members of the board. Three of these are original members, and there have been only three changes on the board in 15 years. The Sanitary Division is one of 8 divisions of the organization. The Sanitary Division in 1923 included the chief, a dairy instructor, and 3 sanitary instructors. Another instructor was added in 1926, and an engineer in 1935. It is interesting to note that 2 of the original staff are still employed, and that only 6 men have been replaced in 15 years. The average tenure of office of those now employed is 10 years.

To facilitate service, the Sanitary Division has been divided into four districts with sanitary instructors in each district. The senior dairy instructor works out of the Stockton office. The chief of the division and the engineer cover the entire county on special investigations.

The yearly report for 1924 indicates that milk sanitation and food sanitation were the principal fields of activity, while housing inspection was in its infancy. There was some supervision of water supplies and sewage connections

and a preponderance of nuisance investigations.

It may be of interest to consider the activities of the division at the present time.

FOOD SANITATION

Inspection includes a check-up of sanitary conditions in each restaurant, drinking establishment, meat and fish market, bakery, grocery store, and candy shop. Considerable experimental work has been done on the sterilization of glassware in drinking establishments, but no method of laboratory check as yet has been developed which seems entirely satisfactory from the standpoint of field use. Some of the methods suggested by various writers on the subject are impracticable in a small health department. Methods which have given some useful results are: A rinse water sampling method suggested by Stone,² and a modification of the swab method as outlined by the sub-committee on the Standard Methods for the Examination of Dishwashing Devices.³

Food poisoning cases are given prompt and thorough epidemiological investigation. Cream pies, home-canned goods, poisonous mushrooms, and canned clams have been involved in some of the more recent investigations.

MILK CONTROL

San Joaquin County and its cities have passed some excellent local milk control laws. General supervision of dairy and milk supplies is under the State Department of Agriculture. This department, wherever a local health department has suitable facilities, has approved a local milk inspection service which enforces all rules and regulations of the State Department. The local service, through continuous education and judicious enforcement of the local and state laws, has succeeded in protecting the public to a high degree.

Milk control includes strict supervi-

sion of pasteurizing plants; dairy farms, milk houses and equipment; weekly laboratory checks of milk; semiannual physical and bacteriological examination of milk handlers; and general observation of dairy herds. (San Joaquin County has recently been adjudged a modified accredited bovine tuberculosis free area.) That the work of the inspection service is effective is evident by comparison. The milk score was 90.32 for the year 1923-1924, and 97.07 for the year 1937-1938. The average total count in the latter year was 7,500 for all grades and 1,800 for pasteurized milk only.

INVESTIGATION OF NUISANCES

Nuisances of all types require a great amount of attention. As one of the cardinal principles of a health department service, all complaints are courteously received and investigated. When the complaint is justified, the cause is eliminated by educational measures if possible; otherwise by court procedure.

Nuisances most frequently investigated include leaky sewers, overflowing cesspools, septic tanks, and drainage systems, promiscuous garbage disposal, odors from home incinerators, animal pens, chicken pens, vermin infestations, and insect ravages.

RABIES CONTROL

Contrary to most health department procedure, the Sanitary Division does not conduct wholesale quarantine, dog eradication, or vaccination programs. Instead, every dog bite reported is investigated thoroughly. The dog or other animal is placed under observation for a 10 day period, and at the end of that time, if no rabies develops, it is released. Any animal suspected of having rabies is held until death or killed under supervision, and the head is examined in the district laboratory. All contacts, both animal and human, are carefully traced. Our ex-

perience indicates that animal rabies seems to have a more or less definite periodicity, and this method of control has served us well. The maximum number of animal rabies reported in any one year was 96. There has not been a human death from rabies since 1921.

INDUSTRIAL SANITATION

Sanitary facilities of factories receive a general check-up. Cleanliness, convenience, and adequacy are the principal items which are noted. The main difficulty encountered in this field seems to be the inability of factory managers to estimate the number of employees correctly where work is seasonal. There is frequent overcrowding of facilities.

All schools are surveyed regarding heat, light, ventilation, water supply, sewage disposal, toilet facilities, safety hazards, and general sanitation, at least once a year.

HOUSING

The Health District is charged with the enforcement of the State Housing Act on all matters of sanitation, ventilation, and occupancy. The elimination of houses unfit for use and the general improvement of housing conditions requires time and energy. As this program usually affects someone's pocket-book, court procedure frequently becomes necessary. Overcrowding, faulty plumbing, and improper use of rooms are perhaps the most frequent violations which the division encounters. During lulls in working seasons, hundreds of agricultural and other laborers from all sections of California loiter in Stockton and congregate in cheaper lodging houses. Twelve thousand Filipinos call Stockton their home. Housing supervision in the Oriental section is a real problem.

RODENT CONTROL

The Sanitary Division has in the

past conducted several programs of rat extermination. However, most of the rodent control work is done by the County Department of Agriculture and the State Bureau of Sanitation. The division coöperates with these two agencies and gives advisory service.

AIR SUPPLY AND VENTILATION

The division has been striving for some time to improve ventilation in restaurants and places of similar nature. Many conferences have been held for the purpose of securing better hood design, and within the past two months an ordinance has been prepared which should insure a decided improvement in the air supply of eating places.

The advent of air conditioning brings with it additional problems. Many of the small installations have little or no engineering design. In fact, a so-called air conditioned establishment may actually be far more uncomfortable than before, due to uncontrolled humidity. Algal growth, mosquito breeding, and waste water disposal are related items which attend the maintenance of air conditioning systems.

WATER SUPPLY

With a few minor exceptions, all water supplies in the district are obtained from drilled and cased wells. There are 18 water supplies classed as public. A number of small joint operation supplies serve from 2 to 10 families in suburban areas. Nearly every farm home has water available under pressure and even home owners within the cities avail themselves of water so easily obtained. It is conservatively estimated that there are more than 6,000 private wells supplying water to residents of the district. The division samples each public supply 24 or more times a year. School supplies are sampled at least once a year and more often as deemed necessary. Private wells are sampled on request or when

indicated by other investigations. There are a number of areas which are subject to inundation during spring floods. Close scrutiny of water sources and advice to area residents during flood periods has been of material aid in the prevention of water-borne diseases, or, perhaps, escape from these has been a matter of good fortune. Surveys of all public water supplies, comprehending complete data, are maintained and prove invaluable as a ready source of information.

The problem of holding a high standard of water quality in private wells is complicated by the increasing use of rural areas for city-like subdivisions. A lot in these areas will average 5,000 square feet. On this lot it is necessary to establish a sewage disposal system and a water supply, as well as a home and a two-car garage. Since there are no ordinances governing the activities of well drillers, the task of well protection is approached from an educational and advisory standpoint. Many conferences with well drillers and pumping equipment men have served to secure some improvement in well construction and more satisfactory protection of the casing top.

Worthy of special mention is the water supply problem of the San Joaquin Delta, an area which lies almost wholly below sea level and is protected from flooding by earth levees. Typhoid fever seemed to be an uncontrollable disease in the early twenties. It was considered impossible to obtain a potable supply of water from local sources, as the surface waters were badly contaminated, and the underground waters were salt laden. Even though water was obtained from upland sources, the Oriental and Mexican population persisted in drinking from filthy drainage ditches and sloughs.

In 1924 the district began an intensive program of immunization and brought typhoid fever under control.

The attack rate in 1924 was 133.4 per 100,000, while in 1937 it was 11.8. The sanitation factor was not particularly instrumental in this change, but the Sanitary Division is working out a solution to the island water problem. The possibilities of water treatment with small inexpensive hypochlorination machines have been carefully ascertained by field studies on a delta ranch, and it has been proved that it is now possible to obtain a potable water supply at small cost to the property owner.

Cross-connections are a particular problem in our cities. In Stockton there are about 400 wells, with so-called "garden connections." Although the division has not embarked on any particular campaign to eliminate such connections, no new ones are being permitted, and some of the largest cross-connections are being located and changed.

SEWERAGE, INDUSTRIAL WASTES, STREAM POLLUTION

It has been pointed out that the county leans heavily on agricultural pursuits. The availability of raw products and the excellent transportation afforded the finished product have made the county a great processing center. Ten canneries, 18 major wineries, 1 cheese factory, 3 milk condensaries, 2 sugar beet refineries, 2 slaughter houses, and 1 paper products plant, mean economic well-being for a community, and a headache for the engineer. These wastes, as a separate problem, or as an additional load on sewage plants that were not designed for such loads, raise many problems. Industrial wastes disposed of in our streams during summer and fall create the greatest pollution load at the time of minimum flow. Of course, the cannery manager will assure you that the water is simply good clean water with some fruit in it. The writer,⁴ in investigations of the sewage load at Stockton, found that the treatment

plants designed for 51,000 people were attempting to handle wastes estimated at 290,000 population equivalent. A serious depletion of oxygen and a decided increase in bacterial contamination were demonstrated in the San Joaquin River. Since this investigation, the City of Stockton has constructed new sewage disposal facilities designed to handle the load.

If wastes are discharged on land, the operating factor is paramount and many field visits, coupled with education and persuasion, are needed to prevent nuisance. How many times has one heard that evaporation takes care of all of the water which is run out upon the land?

As with water supplies, complete surveys of all public sewerage are maintained. These surveys are brought up to date as major changes occur. Treatment plants in the county range from activated sludge to the lowly septic tank.

The division has made it a policy to aid plant operators in a better understanding of the problems which occur. Recently, the engineer arranged a series of meetings for the purpose of giving operators a basic understanding of the fundamentals of sewage treatment and disposal. A bulletin is issued bi-monthly for the purpose of transmitting information to the field.

The problem of private sewage disposal is of prime importance in the suburban areas. The soils of the county range from sand to black adobe, and it is a peculiar quirk of circumstance that has seen the greatest development of small homes in areas where adobe is the principal soil. There are no ordinances in the county which are designed to control private sewage disposal systems, and it is only by constant vigilance and continuous explanation that any improvement is attained. One of the most serious outgrowths of poor disposal has been the development of

the "sewer well." The sewer well is a hole in the ground drilled to water bearing strata. It is used for the purpose of draining effluent from septic tanks and cesspools. Often a sewer well and water well will be drilled to common water bearing strata on the same or adjoining lots. An amendment was made to the State Health Laws in 1935 which made such wells illegal, and many wells have since been abated under that law.

Stream surveys have paved the way for improved sewage disposal. In the past 3 years the division has made independent surveys and coöperative surveys with other agencies, such as the State Bureau of Sanitary Engineering, the State Division of Fish and Game, and the neighboring county health departments.

In a small health unit, the engineer does nearly all of the analytical work. Those of you who have not tried it would be surprised at the amount of field work that can be handled from a small field kit which can go on the seat of a boat or in the back of an automobile. It is hoped that we may preserve our streams in a reasonable state of cleanliness and still do no serious injury to the industrial plants which use them for waste disposal.

REFUSE DISPOSAL

Here again the produce industries are involved. Disposal must be made of any solid matter which is not placed in sewers; fruit wastes, grape pomace, sugar beet pulp, asparagus butts, and celery trimmings are vile-smelling unless properly cared for. Efforts are continually being made to find some use for these waste products. In the case of grape pomace, it has been found that it can be dried and used as fertilizer and stock feed. Beet pulp can be dried and used as feed or fed wet in the locality. Both methods are being used extensively.

Promiscuous garbage dumping by private individuals along the roadside, in vacant lots, and elsewhere has received much study. Better control of garbage collection in cities has been promulgated as a means of solving this problem.

SWIMMING POOL SANITATION

In California, responsibility for the sanitation of swimming pools rests with the local health department under the rules and regulations of the State Board of Health. Examinations are made of all pools in the county and recommendations are made for improvement of pool facilities. Inasmuch as the disease transmission traceable to swimming pools is still somewhat problematical and may be placed in the category of the potential rather than the actual, it is somewhat difficult to educate pool owners and operators to accept the standard of drinking water for swimming purposes. A favorable trend in the right direction can be noticed in the increased tendency of the public to be critical of swimming water. We often find people asking if the "old swimming hole" is safe. Schulmeyer⁵ has emphasized the importance of this trend in this statement:

A pool manager will be more alert to his responsibilities if he is aware that his pool patrons are cognizant and critical of any deviation on his part from fundamental principles of pool and bathhouse hygiene.

CAMP SANITATION

When the field crops are ready, extra labor is the crying need. The migratory worker follows the crops all over California, and San Joaquin County receives its share. During the past spring and summer there have been as many as 7,000 people residing in tents, trailers, and what not, and occupying any available ground which might be used. These camps, at their inception, have few or no sanitary facilities, have poor water sources, and are decidedly over-

crowded. During the season, the entire department is busy visiting transient camps. The principal activity of the Sanitary Division is, of course, the protection of water, improvement of sanitary facilities, and protection against insect-borne diseases such as malaria.

Strangely enough, whether privies of the home-made variety, privies of the U. S. Public Health Service variety, or modern water flush toilets are provided, patrons soon create a filthy condition due to their personal habits. Camp patrols must be rigidly maintained or conditions quickly get out of hand. Certainly such situations offer huge opportunities for education in personal hygiene habits.

In so far as the enforcement of rules and regulations regarding auto camps is concerned, outside of incorporated areas the Health District has no special jurisdiction. By legislative enactment, the State Division of Immigration and Housing was given general control of auto camps in 1931. However, there is a close spirit of coöperation between the local division and the state on all matters of camp sanitation.

There are four mountain recreation camps which are used by San Joaquin County residents and maintained by local organizations. Although these camps are outside the jurisdiction of the Health District, annual visits are made and suggestions are offered for the betterment of all phases of sanitation.

MOSQUITO CONTROL—MALARIA

San Joaquin County has a number of small streams heading in the foothills, which dry up early in the year. As these waters recede, excellent breeding areas are formed.

Eight irrigation districts maintain some 1,500 miles of canal. One thousand miles of drainage ditches carry excess water to tule-grown sloughs and

400 miles of navigable water in the Delta. Twenty-five hundred acres of rice and 8,000 acres of Lodino clover dot the county with miniature lakes. Potholes and seepage channels are prevalent in the flood lands adjacent to the Mokelumne and Stanislaus Rivers. Poorly constructed cesspools, storm water catch basins, and undrained vacant lots are found in suburban districts.

With this rich field of breeding areas to choose from, it is always possible to find mosquitoes. Perhaps the more troublesome of the pest mosquitoes are *Aedes Vexans*, *Aedes Varipalpus*, and *Culex Tarsalis*. *Anopheles Maculipennis* is the prevailing anopheline, although others are present.

Malaria has always been more or less of a problem. Available historical records indicate two peaks of malaria, one in 1917 and one in 1934. Careful epidemiological investigation of each case of malaria is made by the engineer. There is little doubt that the influx of transients from Oklahoma, Arkansas, and Texas precipitated the peak of 1934. Our records show that 59 per cent of the cases were in itinerants. Coöperation of the medical profession in the county made it possible to obtain laboratory confirmations on 86 per cent of the cases reported in 1937.

The district carried on control measures in malarial areas for 4 years. At the present time, advisory service is given groups and private individuals. In the case of local nuisance, remedial measures are required.

INDUSTRIAL HYGIENE

Industrial hygiene is a new field in public health work in California. A State Industrial Hygiene Service was formed in 1937. The engineer and health officer are coöperating with the state on many local problems, among which may be mentioned the use of carbon tetrachloride in dry cleaning establishments, and carbon monoxide

asphyxiation from motor vehicles. Plans are now being made for surveys in wineries to determine the hazards which may exist.

PUBLIC HEALTH PLANNING

It was recognized many years ago that the health agency had an interest in planning, yet as recently as 1927 Dr. Sippy states:

Nevertheless, despite the basic health principle involved in the housing and city planning program, it is all too frequently customary to omit the advice of the health department or its members.

Today the picture has not been materially altered. Even the modern planning engineer of present-day cities rarely attacks planning problems from the public health viewpoint. Perhaps one of the most urgent planning problems in the health district is that of suburban building beyond purely arbitrary city limits. The sanitary hazards have been mentioned elsewhere but are worthy of repetition. Improper sewage disposal, endangered water supplies, overcrowded houses, courts, and apartments, structurally unsound buildings, all challenge the Health District to exert its efforts toward better planning of suburban developments. Analyses of living costs which show false economies, and potential health hazards of the unsupervised community have been canvassed and placed before many people. The answer is "Yes, but I don't have to pay any city taxes."

Within the last two years the Federal Housing Administration program has offered an excellent entry to better health planning. The Federal Housing Administration requires that all private sewage disposal systems and water supplies of houses insured by it shall have certificates of approval from the local health authority. The district has adopted standards which will guarantee a reasonable protection of the home owner and his investment, and these

same standards are used as a basis for recommendation on all private water supplies and sewage disposal systems within the jurisdiction of the district. Since the start of the program, the district has certified 59 water supplies and 91 sewage disposal systems on recommendation of the engineer. Recently one entire subdivision has made Health District approval of the water and sewerage systems a requirement. The Federal Housing Administration is also insisting on better standards of construction, lot area, etc. An architectural inspection service is maintained by the Federal Housing Administration for this purpose.

Political subdivisions within the district are now frequently requesting assistance in the preparation of enforceable ordinances pertaining to sanitation. Auto and trailer camp, and garbage ordinances have been prepared recently.

ENGINEERING

The engineer's part in the work of the division is not easy to define, as he both complements and supplements the work of the remainder of the staff. He serves as an assistant and adviser to the staff on many special problems in the field of food sanitation, dairy sanitation, nuisance investigations, industrial sanitation, housing, air supply and ventilation, refuse disposal, and camp sanitation. Activities which are predominately engineering functions include water supply, sewage disposal and stream pollution, swimming pool sanitation, mosquito control, and industrial hygiene. Public health planning, and public health education are functions of the staff individually and collectively.

DISCUSSION

How do the division activities correspond with the work which is thought to be within the purview of

sanitarians and engineers? Hyde⁷ has divided typical problems and activities in environmental control into 10 general classifications. It would be almost a repetition of our activities to name them. Some of the items he mentions are coöperative enterprises under state jurisdiction; others, due to local conditions, may require only a minimum of attention. Yet there remains little in his classification which has not become a part of the local sanitation service.

Thus a well coördinated staff of four sanitary instructors, a dairy instructor, an engineer, and the division chief, under a health executive who comprehends the full scope of environmental sanita-

tion, serves a county which, due to its characteristics, offers nearly every problem which is considered within the field of sanitation.

A Simple Tellurite Medium for *B. diphtheriae*

NELL PETERSON HALL

*Branch Laboratory, State Department of Public Health,
Champaign, Ill.*

SEVERAL media containing compounds of tellurium have been devised for the isolation of *B. diphtheriae* from mixed cultures. These have been rather difficult to prepare and, for that reason, have not been used in small laboratories and hospital laboratories.

A medium was sought which would be easily prepared yet give as good results as other tellurite media, allowing a more rapid isolation and identification in pure cultures.

HALL'S TELLURITE MEDIUM

Dissolve 4.5 grams of Bacto Cabbage Infusion Agar in 100 cc. of distilled water. Sterilize at 15 lbs. pressure for 30 minutes. Cool to 55° or 60° C. Add 10 cc. of citrated or defibrinated blood (sheep, ox, horse or human) and 10 cc. of a 0.5 per cent aqueous solution of potassium tellurite. The tellurite solution may be stored in the icebox and kept indefinitely.

Pour in plates and cool with tops tilted. Plates are not easily contaminated.

Plates of the medium may be inoculated directly from swabs or from cultures on Loeffler's medium, and it should be noted that at least 18 to 24 hrs. incubation of the plates is as a rule necessary for the naked eye recognition of colonies. Smears may be made and

examined, however, after overnight incubation. In making smears, the entire surface of the inoculated medium should be scraped with the loop to obtain the growth.

Among the numerous advantages possessed by this medium are:

1. It completely inhibits organisms, such as staphylococcus, streptococcus, *M. catarrhalis*, pneumococcus, etc., while the diphtheria bacillus and organisms of the diphtheroid group grow uninhibited, with typical colony appearances. *B. diphtheriae* grows typically as a round, smooth colony, greyish-white or black in color.

2. Petri dishes may be prepared well in advance of the time they are to be used. Plates prepared and kept at icebox temperature 2 or 3 weeks were found to give equally as satisfactory results as those freshly prepared.

3. The medium may be made in very small amounts, making it valuable for small and hospital laboratories.

4. It is especially valuable in the isolation of mixed cultures for tests of virulence.

5. Several cultures (10 or 15) may be put on one plate by marking sections with a red wax pencil.

6. A higher percentage of positives may be obtained on cases for quarantine release. A pure culture of *B. diphtheriae* may be had on this medium with a negative one on Loeffler's medium.

7. It has the advantage over Loeffler's medium of being easy to prepare, and a higher percentage of positives may be obtained.

8. The organisms are much larger than on Loeffler's medium.

EVART GRANT ROUTZAHN

THIS Association has mourned the passing of many persons whose genius has touched its affairs. None were loved more than E.G.R. He wore his mantle of greatness with such unconcern that few were conscious of his immortal spirit until after he had passed by. He was in every sense an apostle of health, loved for his simplicity, his enthusiasm, his essential shyness, his good humor. Like every great teacher his lessons were free of cant and dogma, shunning pompous theory and high sounding phrase.

Mr. Routzahn was born in Dayton, Ohio, January 6, 1869, and was educated in the public schools there. His interest was in social work which he followed for several years. He directed a traveling exhibit for the National Tuberculosis Association from 1906 to 1912. Thereafter, until his retirement in 1934, he was Associate Director of the Department of Surveys and Exhibits of the Russell Sage Foundation.

He joined the American Public Health Association in 1912 and became a Charter Fellow in 1923. In July of that year he began editing the section on Health Education which has been a distinguished part of the *Journal* ever since. His last contribution to this section appears in this issue. There, too, will be found an expression of the regard of his fellow workers in the Health Education Section and in the Committee on American Museum of Hygiene.

For many people Health Education meant E.G.R. Rarely has the personality of one man been so clearly identified for so long with the leadership of a movement. Younger members will forget that he was the first paid employee of the National Tuberculosis Association. He piloted the first tuberculosis exhibit—caravan fashion—over the country, and left in its trail a series of enthusiastic committees most of which developed into local associations that ultimately became a part of the vast machinery for popular health education developed by that association.

It should never be forgotten that it was he who gave health education a place

in the sun in official health work by his successful efforts to establish a Section on Health Education in the American Public Health Association. He worked for recognition of health education as a specialty at a time when to many it was only a name designating a vague activity without technic, method, or purpose. The Section was created largely through his single-handed labors, and in its second year he was one of the three Fellows it could boast. He lived to see it assume its true prominence among the ten Sections, both in numbers and in weight, with a total membership of 600 and a Fellowship of 105. It was typical of him to accept the Vice-Chairmanship of the Section in its first year. He served as Chairman in 1923, and later assumed successively the Secretaryship and again the Vice-Chairmanship. At the Association's New York City meeting in 1937, on the occasion of the Section's 15th anniversary, the Section commemorated that event in the only appropriate fashion—by a testimonial luncheon to Mr. Routzahn. To the many who attended, it was apparent that the accomplishments of the Section and the accomplishments of E.G.R. were one and the same thing.

This many-sided man leaves behind him a record in social work publicity and in adult education as brilliant as that in health education. The members of this Association knew him best in the field of health education, although his book, *Publicity for Social Work*, published in 1928, was as familiar to them as to the social workers for whom it was written. His wife, Mary Swain Routzahn, collaborated with him in the preparation of a similarly widely known *A.B.C. of Exhibit Planning*, published in 1919.

Mr. Routzahn was first and last a collector. He collected friends, converts, ideas, gadgets. His collecting propensities brought rich returns to those who haunted Health Education and Publicity Headquarters at the Association's Annual Meetings. He had built up an encyclopedia of health education materials over a period of twenty years and it was from this incredible store that he drew for the exhibit he conducted each year.

Mr. Routzahn happily combined in his character and intellect the patience of the collector, with the organizing vision of the teacher. His advice has been sought by countless organizations and individuals everywhere. His painstaking efforts to record and portray for his professional colleagues new ideas, suggestions, and improvements in the thousand and one specialized technics embraced in health education, placed his name on many lips, and made him an "institution" within the public health movement—a position which he occupied with modesty and simplicity that in themselves are marks of greatness.

He was a being who loved life and he never lost his youthful spirit.

SANITARY REGULATIONS AS TRADE BARRIERS

PUBLIC health legislation has one and only one legitimate purpose. It is enacted solely to provide legal means for the protection of the health of the people. This it accomplishes by imposing such reasonable restrictions upon the conduct of life, liberty and property as are necessary to promote the common health and general welfare.

Health legislation is not intended as an instrument to favor local business at the expense of outside industry. In recent years, however, there seems to

have been an unfortunate tendency to employ sanitary regulations as an obstacle to the free movement of commerce between the states.

Many specific instances of the misuse of health legislation in placing drastic restrictions upon the legal right to market wholesome commodities, particularly dairy products and other foods, are given in a special report recently submitted to the Secretary of Agriculture by the U. S. Bureau of Agricultural Economics.¹ Health officials will find much that is interesting and provocative in this well documented report.

While conceding that laws and regulations adopted by states, counties, and cities have helped to bring about a tremendous improvement in the sanitary quality of our market milk supplies, this report points out that licensing, inspection, and pasteurization requirements are often discriminatory against outside business, and are enforced in such a manner as to limit the sources of dairy products to local business. As a remedy for this situation, the suggestion is made that Congress adopt uniform sanitary requirements for all dairy products moving in interstate commerce.

Reasonable and valid public health legislation, properly enforced, may of course affect private business, but it is a fundamental principle of law in this country that all such legislation must so operate as to afford to everyone the equal protection of the laws.² State health laws may also legitimately interfere with interstate commerce, but only when their exercise under the police power of the states bears a real and substantial relation to the protection and preservation of the public health. Real or alleged economic necessity is no justification for the capricious use of public health legislation.

The courts of last resort of this country have frequently upheld the legal principle that public health legislation is constitutional and its enforcement by executive departments is valid only when such legislation has an actual public health objective. The courts will look behind the laws for the motives that have actuated their adoption.

Thus, where a city health department attempted by regulation to restrict arbitrarily the inspection area for dairy products entering the city, it was held recently by a United States District Court that the regulation was invalid as an unwarranted interference with a legitimate business.³ So long as the product is wholesome, it cannot be prohibited merely on the capricious grounds of distance.

There are numerous other court decisions to similar effect.⁴ The United States Supreme Court has ruled, for example, that it is unreasonable and improper for a state to require a wholesome food product to be colored pink so as to distinguish it from the competing products of local merchants.⁵

Public health officials are guardians of the people's health, and not monitors for local industry. Free movement of trade between the states is an essential feature of the American plan of government. Health authorities should stick to their own last, and leave the troublesome economic problems of industry to the tender mercies of other appropriate agencies.

PROPRIETARY MEDICINES

THE scientific practitioners of medicine have set up for themselves in recent years a rational therapy in so far as the use of drugs and medicines is concerned. The underlying principles of a rational therapy should be known to every public health official and worker. All medicines should first be classified into secret-formula and non-secret-formula medicines. The terms, proprietary, patent, and nostrum should be well understood. Proprietary means one in which there is some ownership right. It may be a copyrighted name or design on the package or the package itself. It may be that the method of manufacture is not open to everyone. It may have a secret formula. The fact that it is a proprietary medicine does not of itself classify it as either good or bad. One should be opposed as a matter of principle to all secret-formula medicine. There is no such thing as a patent medicine any more. When one uses this term he usually is thinking of a nostrum. Official medicines are those that appear in the *United States Pharmacopoeia*,* the *Homeopathic Pharmacopoeia* of the United States and the *National Formulary*. They appear here under definite names and whether they be a single drug or chemical or combinations of either or both they have definitely non-secret-formulae. Nonofficial medicines comprise all medicines not found in these three books. Of the nonofficial medicines there is a recognized list that is an accepted one. This list comprises some four hundred non-secret-formula medicines found in *New and Nonofficial Remedies*, which is revised annually and to which supplements are issued oftener. The *United States Pharmacopoeia*, the *National Formulary* and *New and Nonofficial Remedies* taken together contain about 1,670 non-secret formula medicines. Should not this be enough for any practising physician or for any hospital? Just think what a joy a medical mathematician could have with combinations and permutations.

The new Food, Drugs and Cosmetics Act passed June 25, 1938, and entirely effective (some parts became effective upon passage) June 25, 1939, will be helpful in giving physicians, hospitals, and consumers much needed knowledge of nostrums. The Act explains that the term "label" means a display of written, printed, or graphic matter upon the immediate container of any article and requires that any word, statement, or other information on the label must be on the outside wrapper also, or the outside wrapper be such that the label is visible through it. The term "labeling" in the Act means all labels and other written, printed, or graphic matter upon any article or any of its containers or wrappers, or accompanying such article. The Regulations add that labeling includes all written, printed, or graphic matter accompanying an article at any time while such article is in interstate commerce or held for sale after shipment or delivery in interstate commerce. This new law requires that a medicine for use by man which contains any of the 17 listed narcotic or hypnotic substances such as barbituric acid, morphine, cocaine, etc., or any chemical derivatives of them that have been designated by regulations as "habit forming" shall contain on the label the name, quantity, and percentage of such substance with the statement "Warning—May be habit forming." The new law also requires that drugs not designated solely by an official name (nonofficial ones) must bear on the label the common or

* Recognized as an official compendium in the Food, Drugs and Cosmetics Act of June, 1938.

usual name if there is one, and if made from two or more ingredients the common or usual name of each ingredient and the name and amount of alcohol, bromides, acétanilid, amidopyrine, thyroid, and fifteen other drugs or any derivative or preparation of them. It explains that if compliance with "this paragraph is impracticable, exemption shall be established by regulations"; but it is difficult to think of a case where it is impracticable. All medicines given an official name must comply with official requirements or else state on the label just how they differ from the official drug.

Physicians and hospitals should limit their drug usage to U.S.P., N.F. and N.N.R. drugs, for, as rapidly as new drugs are clinically tried and found worthy they will be included in one of these works. If it were then possible to convince physicians, clinics, hospitals, and public health officials that whenever case histories are taken the patients should be asked about medicines they have taken recently, some very valuable information would be obtained. It might even lead to learning the cause of some ills. Do we have illnesses due to nostrum taking? It is true that many patients may not always give this information or may give it only in part, but the amount collected would surely be enlightening. A beginning might be made with cathartics, hypnotics, and analgesics, and whoever does this faithfully will in all probability extend his questions later. Someone should make a study of this subject.

PUBLIC HEALTH EDUCATION

THIS section of the Journal is printed for the first time in many years without an asterisk following the title and referring to the modest footnote "Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22nd St., New York, N. Y."

Countless readers have obeyed that direction and turned to Mr. Routzahn for advice and assistance on subjects of such diversity and range as to defy classification.

The abundant source of variegated information which was Mr. Routzahn and the knowledge he shared so generously through this Section and through correspondence are removed by death. Evart Grant Routzahn, the familiar E G R, died on April 24.

The Editorial Board removes the asterisk with profound regret and presents here his unfinished and interrupted work—the work upon which he was engaged for this issue, and which is his last contribution to the *American Journal of Public Health*.

When the Western Branch Meets—July 23–28, 1939, in Oakland, Calif., the Western Branch, A. P. H. A., will offer to—

... members who are interested in health education of the public and health education in the schools an outstanding Health Education Symposium which will take place on four separate half days during the week. Except for one address by an outstanding guest speaker, there will be no formal papers. The Symposium will be presided over by an authority in the field of health education. The entire group will be divided into two main sections—one devoted to school health education, the other to health education of the public. The school health education group in turn will be divided into at least three divisions—one on classroom teaching, one on school health service, and one on physical education and recreation; each of these divisions to be given ample opportunity for round-table discussion of its particular problems and presided over by an outstanding leader in this field. The group interested in health education of the public will in turn be divided into at least four divisions: one on the spoken word; one on printed materials; one on radio, cinema, and pictures; and one on museums and exhibits; each led by an

outstanding authority. After each division has discussed its problems, all will come together under the section chairmen to hear and discuss a summary by each division chairman. The final session will be for the purpose of hearing and discussing a summary report from the two section chairmen, the address of the guest speaker, and a final summary and integration by the general chairman.

Say It With Pictures—If one has a story to tell and is willing to use pictures with a few words only, *Children's Museum News*, monthly issued by Children's Museum, Park Place, Brooklyn, N. Y., is worth examination. Pages are 7 by 9 inches; one or two photographs on each page (they "bleed" to one or more edges of the page); with 30 to 90 words in black face type on a page; dull finish paper.

In the Recent Past—Farm and Home Week, an annual event at Cornell University, included two health lectures a day under auspices of Division of Public Health Education, New York State Department of Health.

Are You Approved by Your Secretary?—How good your secretary is depends quite a lot on how good a boss you are. For everyone doing a health education job is "How to Be a Hero to Your Secretary," by G. Torson, *Saturday Evening Post*, Jan. 7, 1939.

Why Not Use the Blackboard?—Quoted from *The Reporter*, New York (Nov. 1938):

The speakers should use the blackboard to illustrate their talks. With the exception of . . . and . . . , all of the speakers let go a barrage of chatter which would have been infinitely more effective if they had used the blackboard which was available for illustrating their talks.

Why not begin in staff meetings and committee meetings?

A Newspaper Health Supplement—The special edition for 1939 opens with *Better Health*, a tabloid section of *New Haven Sunday Register* for February 26, 1939. 10 cents. A well selected range of contents prepared by state and local authorities.

New Postage Rates—Those who issue books or pamphlets of 24 pages or more, will wish to study the new postage rates for books. Annual reports do not benefit by these rates.

Social Work Year Book—"Social Work Year Book" for 1939 (Russell Sage Foundation, New York, N. Y.) renders a valuable service, even though adult health education receives scant recognition in a sentence or paragraph here and there. Only one of these references of two words gets into the index. Paragraphs will be found on pages 236, 332, 337-338, 419-420, with minor references on pages 333, 335, 336, 340, 341.

For Children—A series of sheets with letters and pictures in outline for coloring come from Health and Clean-

liness Council, Aldwych House, Aldwych, London, W. C. 2. The 4 sheets are 6 by 9 inches. In view of the wide variety of material offered commercially for coloring by children, more use of the idea might be advantageous in health education.

Social Hygiene Publicity Aids—A "Social Hygiene Kit" is offered free to agencies sponsoring community or group meetings. Includes program suggestions: press book with news stories, editorials, etc; talks and spot announcements for radio; lists of available literature, films, exhibits, and other materials; much material on syphilis campaign. Address: American Social Hygiene Association, 50 West 50th Street, New York, N. Y.

Health Magazines—The February, 1939, issue of *Bulletin*, National Tuberculosis Association, 50 West 50th Street, New York, N. Y., includes a helpful annotated list of popular and professional health periodicals. This seems important enough to republish in the *Journal* in several installments. When completed we hope to hear from readers who believe that any omitted periodical should be included. It is likely that libraries would be interested in this check list.

Says the *Bulletin*:

Readers of the *Bulletin* are calling upon various sources for information on magazines and journals in the field of public health. The National Health Library, to which the National Tuberculosis Association contributes, carries a regular file of more than 500 periodicals. Miss Isabel Towner, chief librarian, has prepared for the *Bulletin* a list of some of the frequently used periodicals. We publish this list below with brief annotations as to the type of publication. This list does not include strictly medical journals although from time to time they publish articles of interest to health workers.

Annual Reports—"Visual Review: 1939" is the annual pamphlet issued for school people by Society for Visual

Education, 100 E. Ohio Street, Chicago, Ill. *Free*. Its value to public health workers is in its fresh glimpses of what the schools are doing in audio-visual education. We need to know what is going on inside the schools if we wish to be coworkers, and not merely outsiders trying to inch our way into the schools.

FOR EDUCATION OR REFERENCE

"Are You a Mouse?" Or, will you fight for cleanliness in eating places? Reprint from *Health Officers News Digest*, 30 Rockefeller Plaza, New York, N. Y. *Free*.

"Free and Inexpensive Materials: Maternal, Infant, and Child Welfare." Pamphlet sources. *American Journal of Nursing*, 50 W. 50th Street, New York, N. Y. April, 1939. *35 cents*.

From Bureau of Home Economics, Department of Agriculture, and to be ordered through Superintendent of Documents, Washington, D. C.:

"The Farm-Housing Survey." Physical features of 595,853 farmhouses, *15 cents*.

"Housing Requirements of Farm Families in the United States," by M. Wilson. Suggests "desirable features of comfort and convenience." *10 cents*.

"Make Safety a Habit" is a 172 page pamphlet on personal safety practices issued for the guidance of employees of Continental Oil Co., Oklahoma.

The ninth in a series of annual publications in the interest of street and highway safety. "Lest We Regret" is a 36 page pamphlet in which pictures and text, diagrams and statistics are presented to arouse a sense of responsibility and a desire to do something about highway safety. Quantities for distribution to clubs, schools, and other organizations supplied upon request. Permission is given to reprint anything in the pamphlet. Glossy prints and mats will be available.

"Snakes: How to Know · Friend

from Enemy," by R. S. Eaton. *Red Cross Courier*, Washington, D. C. April, 1939. *10 cents*. Myths and facts; and facts to lessen the death rates.

"Syphilis and Your Town" is a 12 page folder supplementing "Syphilis: Its Cause, Its Spread, Its Cure." Both from U. S. Public Health Service, and sold by Superintendent of Documents, Washington, D. C. \$1.00. for 100 copies.-

The new issue describes the situation in a city of 100,000, and outlines nine major elements in a control program adaptable to different communities. Based on a series of 9 questions.

"These Accidents Were Caused, They Did Not Merely Happen" heads a 2 page spread in *California Safety News*, Sacramento. March, 1939. There are 14 case stories of accidents and what caused them.

"What Councils of Social Agencies Do." Community Chests and Councils, 155 E. 44th Street, New York, N. Y. \$1.00. Background information for health agency members of local councils. The chapter on "Education" includes both self-education and community education.

"What's Your Score?" is a set of statements, some true, some false, which appear in a back page of *Hygeia* in March, 1939 (535 N. Dearborn Street, Chicago, Ill.). The statements are based on articles in the same issue of *Hygeia*. Whether true or false is indicated (on another page) with page reference to the supporting information.

The Department of Social Welfare and Public Health, American Home Economics Association, has a Committee for the Exchange of Radio Scripts. The committee now offers 15 scripts in narrative form, and 31 dialogues, most of which have to do with foods and nutrition. Borrowers pay postage both ways. For a list of scripts, write to:

Pauline Murrah, Nutrition Consultant, Dept. of Health, 125 Worth St., New York, N. Y.

A "different" mimeographed report is that issued by the Anti-Tuberculosis League, 6101 Arcade Building, Seattle, Wash. Letter size pages; one side each leaf blank; large size cartoon characters on several pages ask significant questions—which are answered. A slightly more opaque paper would have given a better effect, and slip sheeting would have aided.

"Health Promotion Week" in Illinois. May 1-7, 1939. State Department of Health, Springfield.

MAGAZINE ARTICLES

"April May-Day," by E. S. Countryman. *Public Health Nursing*, 50 West 50th Street, New York, N. Y., February 1939. 35 cents. Some drawbacks; how to get the most out of the day.

"Hospital Visitors." Editorial. *Hospitals*, 18 E. Division St., Chicago, Ill. April, 1939. Some problems to be met. By means of the radio, leaflets, and the press, the community should be brought to the realization that visiting the patient in a hospital may be misdirected sympathy which taxes the strength of the patient and retards his speedy recover. (With much wider

application than the hospital.—Editor)

"Prompt Registration of Copyright and Its Publicity Value," an article in *Publishers Weekly*, 62 W. 45th St., New York, N. Y. (Feb. 18, 1939; 15 cents) tells how it is to the advantage of publishers to send their new books promptly to Library of Congress. The delinquents include many special organizations or their small city publishers.

"Selling Health in the Mountains," by E. L. Tiffany. *Public Health Nursing*, 50 West 50th Street, New York, N. Y., Feb. 1939. 35 cents.

A colorful tale of a nurse's work with the hill people of Eastern Tennessee, where the health department is introducing itself to a people hesitant to accept change.

NEW

Not new in B.C., but new to us is *Bulletin*, British Columbia Board of Health, Victoria. Mimeographed.

"Contents" on cover. A brief article about "A woman who made history," distributed by the Health League of Canada, shows a good use being made of "Typhoid Mary."

Health Section News Letter. World Federation of Education Associations, 200 Fifth Avenue, New York, N. Y.

EVART G. ROUTZAHN

MEMBERS of the Public Health Education Section of the American Public Health Association deeply mourn the loss of their leader and friend, Evart G. Routzahn. It is almost impossible for us to think of the Section without him for it was his personality that gave it zest and color. At a time when only a scattered few were giving serious thought to health education as a specialty of public health E G R saw the advantage of banding such workers together. He nursed the foundling Section, laid on the doorstep of the American Public Health Association, until it was accepted as a lusty member of the public health family. All through the years he guided its stumbling gait and happily he enjoyed the satisfaction of seeing his child grow sturdy and respected.

Though E G R never sought honor nor office, both were thrust upon him and he carried them well. For the sheer love of the cause he labored for

its well-being. Each month his cryptic paragraphs in the *Journal* stimulated us; many of us turned first to his pages. Annually his exhibit was the rallying place of all loyal members of the Section, and many a youngster and veteran in the field of health education found treasure there. To E G R we turned often and never in vain. With the advice he gave there was always a glint of humor, with his service always a beaming smile. His criticism, eagerly sought, was always penetrating but never with a sting. Mostly we loved him for his friendliness—for his bubbling good will.

We thank God that the bench-mark E G R is indelibly impressed upon the Public Health Education Section. Time, which mellows sorrow, will never efface that bench-mark. We who worked, and planned, and laughed with him have been enriched by the comradeship, and that wealth grows more precious with his passing.

AN APPRECIATION
of
EVART GRANT ROUTZAHN

Adopted by the Committee on American Museum of Hygiene of the American Public Health Association, upon his death, April 24, 1939.

EVART GRANT ROUTZAHN, pioneer in health education and member of the Committee on American Museum of Hygiene of the American Public Health Association, died in the City of New York on April 24, 1939. Whereupon the following minute was adopted by this Committee:

Upon his death, the Committee on American Museum of Hygiene wishes to express appreciation of the singular service Evart Grant Routzahn has ren-

dered the public health movement and the American Public Health Association, through the latter's Committee on American Museum of Hygiene, of which he was a charter member; and to record the admiration and affection with which his rare ability, tact, and generous devotion in the cause of health education have inspired his associates on this committee.

An intimate friend and adviser of individual members of this committee, Mr. Routzahn gave his discerning insight, sagacious judgment, and broad experience to the initiation of formal health education technics in the United States during the past quarter century

and to many other philanthropic and professional services devoted to promotion of the general welfare. He was among the pioneers in health education who maintained a courageous confidence in the utility of visual educational method in raising the level of national vitality by spreading health knowledge among the masses. To this cause, long retarded by meager resources and professional apathy, he gave generously of his time and energy; and by contribution of his vision, steadfastness of purpose, and creative leadership, helped to make the work of this committee effective and its influence widespread.

It is of special regret to members

of this committee individually that Evart Grant Routzahn did not live to see the exhibits on medical science and public health at the New York World's Fair 1939, which were part of his planning and which tangibly express a scheme of educational method that he labored so devotedly to introduce into the American health education scene.

The committee wishes to express its deep sympathy to Mr. Routzahn's wife, Mary Swain Routzahn, and to other members of his family. His inspiration, his personality and his loyal service will abide in the future work of this committee, and in the memories and work of its members.

BOOKS AND REPORTS

A Fundamental Approach to Bacteriology—By *Courtland Sawin Mudge and Floyd Russell Smith*. San Francisco: J. W. Stacey, 1939. 265 pp. Price, \$2.50.

As the authors say in their preface, this book does not quite reach the dignity of a textbook but it is not the conventional laboratory manual. The dominant idea of the plan which the authors have adopted is to gain and maintain the interest of students by grounding them in basic principles which provide them with the reason for doing the work set before them. This does away with the drudgery of dry memorizing. They are taught to know why they are doing things instead of doing them by rote. The authors point out that much of the new work constantly going on does not get into textbooks for a long time, or not at all, and they have attempted successfully to avoid this fault of teaching.

The book is an excellent laboratory guide for general bacteriology. The material is well selected and well prepared in simple and interesting fashion. Much of the "newer work" not found in the ordinary textbook is included, such as physical phenomena, oxidation-reduction, statistical methods, etc. The arrangement of the book is good and it contains a number of excellent illustrations. It is written in rather unusual style calculated to hold the interest of the student.

The printing and make-up of the book are good and it has ring binding which has considerable advantage for laboratory work, since the book lies flat at any opening.

We wish that the authors had not indulged in the all too prevalent trend of having an introduction by someone not connected with the writing of the book. Such an introduction is of necessity an apology, though intended as a boost. "Good wine needs no bush."

This laboratory manual can be entirely recommended for the purpose for which it was designed.

MAZÏCK P. RAVENEL

Play and Mental Health, Principles and Practice for Teachers—By *John Eisle Davis*. New York: A. S. Barnes Co., 1938. 202 pp. Price, \$2.50.

So much has been written on play that is ephemeral, that it is a pleasure to review a book based upon scientific observation and practical experience. The author presents his material from the developmental, dynamic standpoint with special emphasis upon the mental hygiene value of properly conditioned play. In his words, "Play is this modifiable experience which in the hands of the child and the hygienically trained teacher possesses so many elements out of which to organize and project lessons vitally related to the child's most effective growth and wholesome development," play may be regarded either as a conflict or as co-operative competition. Both of these concepts are logically considered. "Modern educators emphasize coöperation as the effective keynote and the criterion of happy conduct particularly in play."

The chapters on "Play and Psychic Adjustment" and "Play and Adjust-

ment to the Outside World" are stimulating reading and are conducive to clearer thinking in the field of education. "The teacher should never forget that it is not activity alone but what activity means to the child that determines its value." The outcome of ideal play should be happy socialization of the child. Each chapter is followed by a well selected bibliography. The hygienic objectives in play education are succinctly stated at the end.

RICHARD A. BOLT

The Etiology of Trachoma—By *Louis A. Julianelle, Ph.D.* New York: Commonwealth Fund, 1938. 248 pp. Price, \$3.25.

For those attempting to follow the expanding area of the virus infections, this volume should prove of great interest.

It is the first extensive work dealing with the etiology of this world-wide disease since 1914. It is a not too detailed, judicial presentation of most of the research that has been done on trachoma. The major portion of the monograph is given to a consideration of the more recent studies made by the author and others which have resulted in the present concept that trachoma is probably a virus infection.

It goes even farther. It develops the interesting picture of the two virus diseases of the human conjunctiva, trachoma and inclusion-body blennorrhoea, which are probably closely related but it is only the latter which has been found, so far, naturally to infect the genitourinary passages of any animal.

The three main problems of the research worker in this field have been:

- (a) Finding a suitable experimental animal
- (b) Unsolved problems connected with the successful passage of the virus through a filter
- (c) Failure so far in culturing the virus on living tissue

Certainly, after reading this work

one must conclude that trachoma is a disease of the conjunctiva, transmitted by an infectious agent which passes a filter. Whether this infectious agent is the inclusion-body found in the epithelial cells of the conjunctiva in trachoma is not yet proved although Thygeson has certainly made a good case for it.

C. E. RICE

A Short Encyclopaedia for Nurses—By *Evelyn C. Pearce.* (3rd ed.) New York: Dutton, 1939. 686 pp. Price, \$3.50.

It has been a real pleasure to study this book which goes well as a companion piece to *A General Textbook of Nursing*, by the same author. Although not so stated on the title page, this is a 3rd edition, in which the author has taken advantage of the reviews made of the former ones. The greatest change appears to be that an index has been added, which the author believes will be a help to readers.

Not in the way of criticism, but as a question which has long dwelt in the mind of the reviewer, we may ask whether or not it is wise to make things too easy for students. Of course, the book is not intended to take the place of thorough study on the part of the nurse, but is an excellent reference book and refresher, both for students and teachers.

The printing and make-up are excellent. Written by an Englishwoman and printed in England, we find the English spelling of many words which have been shortened in our typical American haste. For the purpose for which it is designed it can be unreservedly recommended.

MAZÏCK P. RAVENEL

Public Health Administration in Maryland—By *Maryland State Planning Commission, Baltimore, Md.,* 1938. 153 pp. Price, \$1.00.

In these days of rapid development

of public health administration, this comprehensive review of the structure, functions, administration, and relationships of the state and county health organizations in Maryland is both constructive and timely.

The Chairman of the Commission, Abel Wolman, calls attention to guiding principles disclosed in the report which rest upon such basic considerations as the following:

1. Trained efficient personnel is indispensable (perhaps the most important factor) in the adequate functioning of any public health organization.

2. The formulation of a program with obtainable measurable objectives is a prerequisite to future action.

3. Since the effectiveness, development, and integration of the various elements in county government may aid or hinder the development of satisfactory health services, an effort must be made to coordinate and integrate all of the public activities in each county, so that the taxpayers may receive for each dollar expended, the maximum of public health and welfare.

Other factors emphasized are the importance of cooperation between official central and local units and unofficial agencies, utilization of interests of lay advisory groups, extension of health education, development of research facilities to a higher degree, and consolidation of all state health functions into one State Health Department.

The report is divided into four parts. Part I deals with administrative and technical services; Part II gives consideration to a special county government project in which such services as public health, education, social and economic welfare would be integrated as interrelated members of a unified county program under the leadership of a trained county coordinator; Part III comprises an administrative study of official and nonofficial health and welfare organizations; Part IV consists of a survey of Anne Arundel County, with special reference to public health, medical care, and social welfare.

The report is arranged in a somewhat novel manner, each major section containing a series of challenging questions coupled with comments on practical aspects of the problems studied, factual data, and suggestions for future planning. Coming from a jurisdiction in which the efficiency of the state health department has long been recognized, this study offers much solid food for any administrator of public health who is hungry for ideas. The report is likewise full of useful information and stimulating suggestions for the student of government.

IRA V. HISCOCK

Health at Fifty—Edited by William H. Robey. Cambridge: Harvard University Press, 1939. 299 pp. Price, \$3.00.

For 33 years the Harvard Medical School has sponsored a series of free Sunday afternoon lectures on medical subjects. The attendance has been large and there have been many demands for copies of the lectures. As a result, 12 of the most popular lectures given during the past 3 years have been selected and are now published in this volume. These are on subjects which are of interest to everyone and about which one section or the other of the public is constantly seeking information.

The editor very properly warns against misunderstanding the title of the book, since health at 50 years of age implies the best sort of care during childhood and adolescence. The title, however, is good. It is constantly being pointed out that the prolongation of life in America, about which we boast, is due to the saving of life during the first few years and that we have done little toward conservation after middle life. These lectures are devoted to that period of life.

The lectures are written for the laity in language that can be easily understood by anyone with ordinary educa-

tion. It is an extremely useful book, authentic in every detail, which deserves a place in every public library. The printing and make-up are excellent. There are no illustrations.

MAZÏCK P. RAVENEL

Pediatric Nursing—By *M. Corrinne Bancroft, Elizabeth Pierce and Bessie Cutler* (3rd ed., completely revised, reset, enlarged). New York: Macmillan, 1938. 652 pp. Price, \$3.00.

This new edition brings the material up to date and gives an excellent idea as to the functions of the nurse in her relations to children. Part I treats of normal growth and development and general hygienic care, including nutrition. One is impressed with the preventive aspects of pediatrics and with the consideration given to mental and emotional development.

Part II describes in systematic manner the general nursing procedures basic to effective nursing. The content is well organized, specific in details, and illustrates the important methods and devices.

Part III is devoted to nursing techniques in the diseases of infancy and childhood. It takes up in order the most important diseases of children and brings to bear upon them the most approved methods of treatment from the standpoint of modern pediatrics and pediatric nursing. Suggested references are given at the end of the chapters, and a list of play materials and books suitable for children at various age levels completes the volume. The format of the book is excellent and it is bound in attractive semi-flexible covers.

RICHARD A. BOLT

William B. Wherry—Bacteriologist—By *Martin Fischer*. Springfield, Ill.: Thomas, 1938. 294 pp. Price, \$4.00.

This biography, printed for private

distribution, represents a labor of love designed to perpetuate the memory of one who was a modest, kindly, Christian gentleman and a scientist of the purest integrity.

The life of the man is sketched by Professor Fischer from the cradle to the grave; the author evidently had access to private records for data which otherwise would not have been available.

The reviewer is concerned here only with the medical and scientific elements of Wherry's career; he came under the influence of Ludvig Hektoen, Theobald Smith, and Edwin O. Jordan early in his professional life, and naturally much was expected of the young man. The work of Wherry in the Philippines, in Montana, in California, in Cincinnati and elsewhere is all sketched in with suitable quotations from letters written to him or by him as well as with references to published material.

His discovery of plague infection among California ground squirrels is set forth at some length and given the importance it deserves. To complete the history it may be proper to add that Rupert Blue, who later became the Surgeon General of the U. S. Public Health Service, had long been convinced on epidemiological grounds that plague was present among the ground squirrels of California and that occasionally human infections came from that source. Fischer seems to criticize the lack of effective action that might have been taken upon the discovery of plague among ground squirrels; at first glance such an attitude seems justified, but subsequent developments leave one in doubt as to whether anything useful could have been accomplished in the way of suppressing what we currently speak of as "sylvatic plague"; experience has taught us a great deal during the intervening thirty years.

Wherry's discovery of the etiologic

nature of the human disease entity we now know as Tularaemia, and his addition of a new host (the rabbit)—perhaps the most important host from the point of view of clinical medicine—were clearly set forth.

Apparently, in spite of a meticulously careful technic, Wherry was not to escape the common fate of those who carry on investigations on *Bacterium tularensis* in the laboratory; he almost certainly acquired the infection.

Fischer does not bring out quite so clearly as might have been expected Wherry's attitude toward superficial scientific workers; the kindest designation he had for such was "pseudoscientists."

Wherry was constantly being distracted by offers of teaching and research positions but he never allowed himself to be guided by any consideration other than the possible opportunities for rendering greater service in the advance of medical science. Viewed superficially, many offers might seem to have been more promising than the one he elected to accept or retain, but always his sure insight guided him well in making his decisions.

We can share Fischer's admiration for Wherry and his achievements without necessarily accepting all of his published work as convincing; for example, we believe too much importance is attached to the work on the cultivation of the leprosy bacillus, and to the treatment of typhoid fever with a vaccine.

Wherry's more important fields of work are well known, but the book furnishes a complete bibliography. The sum total of his important research is very creditable and becomes even more so when one appreciates the physical handicap (cardiac) under which the man worked for at least the last 40 years of his life.

One who stood with Wherry by the bedside of patients suffering from

plague, cholera, or other tropical diseases, opposite him at the autopsy table in the San Lazaro Hospital in Manila, who worked by his side in the laboratory at San Francisco and later in the Hygienic Laboratory (now the National Institute of Health) at Washington, D. C., feels that Fischer has rendered a distinct service in making this biography available to the wide circle of Wherry's admirers and friends.

The volume is a notable example of the printer's art, a suitable vehicle for a memorial of such a man as the one whose life is told therein.

GEORGE W. MCCOY

Modern Sewage Disposal—Langdon Pearse, Editor. New York: Federation of Sewage Works Associations, 1938. 371 pp. Price, \$2.50 to Sewage Works Journal subscribers; \$3.50 to others.

The attempt to commemorate the tenth anniversary of the founding of the Federation of Sewage Works Associations by publishing a volume containing what might be a report of a convention of the association has resulted in an outstanding contribution to the science of sewage disposal and treatment. Under the experienced editorship of Langdon Pearse and Dr. F. W. Mohlman, both from the Sanitary District of Chicago, the book has attained the position of an authoritative compendium of much that has happened in sewage treatment during its entire development.

Beginning with an introduction by Prof. C. G. Hyde reviewing sewage treatment during the past fifty years in the United States, the volume is subsequently divided into four general sections.

"Sewage Treatment Practice" contains histories and descriptions of all the underlying principles of disposal, the various types of plants developed to utilize these principles and the

appurtenances added to perfect the operation of these plants.

"Sewage Research" describes the problems to be solved and the personnel, methods, and equipment for doing this. The bibliographies in this section are outstanding for their complete coverage of this subject.

Under "Regional and National Aspects," sewage disposal methods in Great Britain, England, South Africa, the Netherlands, and Germany are described.

In "Industrial Wastes" the effects of this waste on sewage treatment and the tremendous problems involved are presented.

Each of these four sections is divided into 31 topics which are discussed by the outstanding authorities of the world. This, together with the fact that each topic is carefully written, makes adverse criticism improbable. Many papers are completed with excellent bibliographies.

Not only will this volume serve as a reference for historical research in sanitary engineering, but it could, at the present time, serve admirably as a text on sewage disposal and as a disposal plant operator's manual.

F. J. MAIER

Research and Statistical Methodology: Books and Reviews, 1933-1938—Oscar Krisen Buross, Editor. New Brunswick, N. J.: Rutgers University Press, 1938. 100 pp. Price, \$1.25.

This publication is a compendium of reviews of statistical literature published from January 1, 1933, to November 15, 1938. Books are classified under three separate indices (a) professional field, (b) titles, and (c) authors and reviews.

Listed under "Medical and Vital Statistics" are books by Davenport and Ekas; Elderton; Fisher and Yates; Mainland; and Hill. Unfortunately during the period covered few books

on vital statistics have been written and the publications covered are not indicative of the texts currently in use. Publications such as Pearl's *Medical Biometry and Statistics* (1930), Newsholme's *Vital Statistics* (1924) deserve mention. These might well have been included in a supplementary list with back publications for other fields.

The work fills a definite need as a guide to recent statistical literature and should prove of particular interest to statisticians and educators.

LOUIS FELDMAN

Sir Thomas Roddick—By H. E. MacDermot, M.D. Toronto: Macmillan Company of Canada, 1938. 160 pp. Price, \$2.00.

Sir Thomas Roddick is, without question, one of the outstanding figures in the medical life of Canada. Born in 1846, in Newfoundland, he secured his early education in that country and, later on, in Nova Scotia. He came to McGill University for his medical studies and was graduated in 1868.

His biography, as presented by Dr. H. E. MacDermot, a recognized medical historian, is divided into three sections. The first covers the introduction of antiseptic surgery, in which Roddick played a leading rôle. The second deals with his military career as Chief of Medical Staff in the Field during the Riel Rebellion in 1885. The third section describes Roddick's part in the securing of "The Canada Medical Act," which achieved certain national uniformity in medical licensure without interfering with provincial rights.

Dr. MacDermot has told this story of Canadian Medicine in a simple, readable, and entertaining manner. While Roddick naturally dominates the theme, around his figure are pictured the important happenings of his day, not only medical, but political and social as well. Of particular value are the recorded comments of those who

were younger contemporaries of Roddick and who are still active members of society.

The book will have an appeal for public health workers as Roddick taught Hygiene in the Faculty of

Medicine at McGill University. They will be interested too in the recital of the application of Lister's methods in surgery, and of the various problems in hygiene which Roddick faced in the Riel Rebellion. GRANT FLEMING

BOOKS RECEIVED

- A POCKET MEDICAL DICTIONARY.** Compiled by Lois Oakes and assisted by Thomas B. Davie. (3rd ed.) Philadelphia: Reilly, 1938. 397 pp. Price, \$1.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Causes of Improvement Analyzed—For a 20 year period ending in 1931, there was no demonstrable downward trend in Cleveland's high puerperal mortality rate. Since then the rate has gone from over seven to about three. That the decline in other cities should be similarly studied and analyzed all will agree.

BOLT, R. A. Reduction of Maternal Mortality in Cleveland. J.A.M.A. 112, 16:1543 (Apr. 22), 1939.

Immunity to Tuberculosis—Wishful thinking that childhood infection with tuberculosis immunizes against later breakdowns from reinfection finds no support in this follow-up study of children tested with tuberculin. The ratio of later deaths among reactors and among negatives is 38 to 1.

CHIU, P. T. Y., *et al.* The Fate of Children with Primary Tuberculosis. J.A.M.A. 112, 14:1306 (Apr. 8), 1939.

Responsibility for Milk Safeguards—Every state health department should employ at least one sanitary engineer full time on milk supervision. No pasteurization plant should be constructed and no equipment installed or modified without the approval of the milk sanitation engineer. This official should have adequate training, which many have not had. The reasons for the eminently sound proposals are set forth in convincing array.

FRANK, L. C. Engineering Problems in Milk Sanitation. Pub. Health Rep. 54, 13: 513 (Mar. 31), 1939.

Blonds, TB, and Vitamin A—More than half the tuberculous persons tested gave evidence of vitamin A deficiency, and the extent of this de-

ficiency paralleled the severity of the tuberculosis infection. Observations of "normal" blonds and brunettes are also recorded.

GETZ, H. R., *et al.* Vitamin A Deficiency in Normal and Tuberculous Persons. J.A.M.A. 112, 14:1308 (Apr. 8), 1939.

Is This New to America?—A diphtheria scratch test similar to the von Pirquet was found specific for the disease. It has the advantages of simpler technic, requiring no syringe, is less time consuming, and slightly more sensitive.

GROZIN, M. Diphtheria Scratch Test. Am. J. Dis. Child. 57, 3:564 (Mar.), 1939.

Another Reason for Goiter Prophylaxis—Statistical evidence is presented which again suggests a relation between goiter and cancer. Therefore iodine prophylaxis, together with desiccated thyroid for the aged, may be a precaution worth taking from the standpoint of cancer also.

McCLENDON, J. F. The Statistical Relation Between Goitre and Cancer. Am. J. Cancer. 35, 4:554 (Apr.), 1939.

Basis of Sanitation—Varying degrees of participation by federal, state, and local health agencies in the sanitary engineering program are discussed and the conclusion is reached that though expansion in many state divisions is needed, the great weakness is in local units.

McLAUGHLIN, A. J. A Basic Program of Sanitation. Health Officer. 3, 12:411 (Apr.), 1939.

Confession Still Good for the Soul—It is difficult to believe, write these authors, that, for all our success in early diagnosis, improved facilities for

treatment, and progressive education, the death rates can be so high (among high school students with tuberculosis), that our case control can be so poor, and that deaths are greater among incipient than among advanced cases.

NOVAK, J. B., and KRUGLICK, J. S. End Result of a Tuberculosis Case-Finding Project. *J.A.M.A.* 112, 5:1452 (Apr. 15), 1939.

Modern Health Crusade—Words of wisdom about health education, ending with this: if we really believed in the importance and value of health education, much more of it would be carried out! While lip service to prevention is common, every official knows how much harder it is to carry through a preventive scheme than to secure support for remedial work.

SAVAGE, W. The Media and Organization of Health Education. *J. Roy. San. Inst.* 2, 4:256 (Apr.), 1939.

Fertile Health Exhibit Ideas—Some of the newer technics found useful at the New York Museum of Science and Industry are these: spotlighted demonstrations; scientific side-shows to high-spot features and give variety; tie-up of scientific exhibit with appropriate subjects running in the commercial movie houses; luring various groups by movie "screen tests" of golf stroke, or demonstration of some special scientific technic. This limited list should convince you of the value of this paper, but there is a lot more.

SHAW, R. P. New Developments in Scientific Museum Techniques and Procedures. *Sci. Month.* 48, 5:443 (May), 1939.

Well-Fed Mothers-to-Be—Optimal diet for pregnancy should include fruit, eggs (3), milk (1 qt.), meat, vegetables, butter (with other foods added to give sufficient calories), at least 3 grains of ferrous sulphate and 800 units of vitamin D. The requirement of food factors for optimal nutrition are set forth in a useful table, and there is much

more of interest to maternal hygienists.

STRAUSS, M. B. Nutritional Requirements and Deficiencies in Pregnancy. *J. Am. Dietet. A.* 15, 4:231 (Apr.), 1939.

Scarlet Fever Immunization and Rash—Active immunization with scarlatinal streptococcus toxin which changed the positive Dick test to negative had no demonstrable effect upon certain immunological properties of the blood toward streptococci. The author does not comment on these findings in a study to determine the expected benefits from immunization against scarlet fever, but one may arrive at some assumptions of his own by reading the whole paper.

STRUMIA, M. M. Immunologic Studies in Active Vaccination Against Scarlet Fever. *J. Immunol.* 36, 4:301 (Apr.), 1939.

Do Second Attacks of Polio Occur?—Experiments are reported upon monkeys recovered from poliomyelitis and reinfected with material from acute measles cases. New paralysis developing without the typical inflammatory changes of polio suggests that supposedly second attacks of the latter disease in humans may be due to some other infection.

TOOMEY, J. A., and WEAVER, H. M. Experimental Paralysis in Monkeys Completely Recovered from Poliomyelitis. *Am. J. Dis. Child.* 57, 3:541 (Mar.), 1939.

We Have Enough Bugs of Our Own—Listed are the 650 assorted insects: mosquitoes, flies, beetles, wasps, ants, moths, cock roaches, and chinch bugs, brought into the U. S. on airplanes from South and Central American ports.

WELCH, E. V. Insects Found on Aircraft at Miami, Florida, in 1938. *Pub. Health Rep.* 54, 14:561 (Apr. 7), 1939.

Brains, Courage, Money, Patience Needed—Striking and useful are these statistics: half of the venereal infections are acquired innocently: half the

syphilis infections are acquired in the 20 to 30 year age group: the sex ratio is 3 men to each 2 women. One in every 12 pregnant women (in 15 city clinics) had syphilis. It costs the country 50 million dollars each year to keep the paretics in the comfort to which they are accustomed!

WILBUR, R. L. Social Hygiene—A Task of All the People. *J. Social Hyg.* 25, 3:113 (Mar.), 1939.

Reference Item—The work of each of the divisions of the Canadian National Health Section is described. The organization is much like that of the U. S. Public Health Service, it would seem.

WODEHOUSE, R. E., *et al.* The Health Section of the Department of Pensions and National Health, Canada. *Canad. Pub. Health J.* 30, 3:119 (Mar.), 1939.

How Much Maternal Care?—Every patient should be examined at the end of the lying-in period, from 10 to 14 days after delivery. In normal cases a second examination should be made at the clinic 6 weeks after delivery. What should be done at each is set forth by this British authority. These suggestions would improve some post-natal practice hereabouts.

WOOD, J. L. M. The Scope of the Post-Natal Examination. *Pub. Health.* 52, 7:197 (Apr.), 1937.

ASSOCIATION NEWS

A STATEMENT OF THE POSITION OF THE AMERICAN PUBLIC HEALTH ASSOCIATION WITH REFERENCE TO THE NATIONAL HEALTH BILL OF 1939 (S. 1620)

as made by Abel Wolman, Dr.Eng., President of the Association, before the
Senate Committee on Education and Labor, May 4, 1939

THE American Public Health Association has approved in principle the major aspects of the National Health Program and has directed a committee to lend the assistance of this professional society of public health workers in order that these principles may be translated into effective action.

The National Health Bill of 1939 has been studiously compared in detail with the principles declared by the Association as desirable or requisite for such a document. We conclude that, with but one major exception, this effort to implement the National Health Program meets the conditions published by the Association.

The Association approves the evidences of effective interest of the federal government in the health of the nation.

We accept the proofs presented again and again that large areas of our country do not have the benefits of adequate health service.

We believe that state health departments and local health agencies are necessary to provide indispensable services.

We specifically endorse the recommendations of the Technical Committee on Medical Care as they provide for (1) expansion of public health services including maternity and infancy, (2) expansion of hospital facilities both general and special, (3) provision of essential medical, hospital, and nursing care as required to persons unable to support such care from their own re-

sources, (4) compensation against wage loss through sickness.

We are gratified to find these four recommendations all embodied in the Wagner Bill.

We believe that wide latitude should be allowed the states in the definition of the population to be served and the method of providing medical services. Here again we note that the Wagner Bill agrees.

We believe that these benefits should be provided for the whole population, and are pleased to note that the National Health Act of 1939 specifies that a plan to provide state-wide coverage at once or in not more than 6 years must be submitted in order for a state to qualify for federal aid.

We further believe that the primary federal function in this field is to give financial and technical aid to states for approved programs. We note that the Wagner Bill does not depart from this primary function.

We believe that it is desirable that a single state agency, the health department, should be administratively responsible for all the provisions of the National Health Program. We note that the Wagner Bill agrees in general, except on the administrative responsibility of the disability compensation provisions.

We believe that the state health department can provide better personnel and maintain higher standards for these services than any other state

agency. We find no apparent disagreement with this position in the Bill.

We believe that qualified advice will be requisite from several professional groups concerned. We note that it is provided for in the Bill, though in a somewhat cumbersome fashion.

We believe that increased funds for training purposes will be essential, and we note that these are provided in the Bill.

We believe that the program should be developed around and based upon existing preventive health services, and we find provisions to this effect in the Act.

We believe that wide latitude must be given to the states in defining not only the population to be served and in the selection of the method of providing medical service but also in the method of raising funds in the states. We believe this latitude is embodied in the Wagner Act.

We believe that the fundamental objectives of this program are, first, the conservation of health and vitality and, second, the reduction of the rôle of sickness as a cause of poverty and dependency. We find no disagreement with these objectives in the Wagner Act.

We believe that the expansion of public health and maternal and child health services, the expansion of hospital, clinic, and other institutional facilities, and the provision of medical care for the medically needy should have priority in initiation. We assume that under the Bill as proposed the states are left with discretion sufficient to choose the items to be developed and the order in which they will be begun.

We believe that the existing provisions for state aid under the Social Security Act constitute a good framework for expansion, and we note that the Wagner Act is an amendment and an expansion of the Social Security Act.

We believe that state programs in order to be approved must provide for

the maintenance of high personnel standards, and we believe that federal aid should be withheld on substandard services. The concurrence of the National Health Bill is noted with approval.

We believe that federal authorities should have power to establish minimum standards after consultation with competent advisory bodies. Again we note agreement of the Wagner Act.

We believe that federal aid should be conditioned on the inclusion in the state plans of adequate safeguards for standards in general, and this we find included in the Wagner Act.

We believe that the extension and improvement of public health services requires the integration of health services at the federal level under one cabinet officer, preferably a Secretary of Health.

We note here a major divergence in the draft of the National Health Act of 1939 which makes the Children's Bureau responsible for maternal, infant, child hygiene, and crippled children's services, whereas the U. S. Public Health Service is to be responsible for general public health work, for investigation, and for hospitals and health centers, and the Social Security Board is to be responsible for the medical care features and for disability compensation.

In this connection we have noted with interest that the recent reorganization order transfers the U. S. Public Health Service and the Social Security Board to a new independent agency without Cabinet representation. No clear provisions for coördination are made. This may therefore be consolidation without coördination, particularly since the Children's Bureau is left in the Department of Labor and various other federal agencies such as the medical service of the Indian Service are left where they are.

It is therefore apparent that the Wagner Act meets the recommendations

of the American Public Health Association in practically all respects excepting the failure to make a single federal agency responsible for all features of the Act. In this respect the National Health Act of 1939 even further complicates the federal administration of health services by imposing upon the Social Security Board a new responsibility for which it now has neither staff nor experience.

It is further noted that although advisory councils are requisite both at the federal and state level, the provisions as made by Sections 503, 513, 603, 1203, 1206, and 1303 will require a total of about 262 separate councils. We believe that these are too numerous

and unwieldy. It would perhaps suffice to provide for one council to each federal agency responsible under this Act and for one council to each state agency chosen for state responsibilities. This would reduce the number probably to less than one hundred. Nevertheless, the membership, the duties and the responsibilities of these councils are still vague. We believe that these details of advisory councils, their number and their duties and responsibilities are matters that can well be cleared in conference.

With the above exceptions we believe that the National Health Act of 1939 can be approved as a device to implement the National Health Program.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Samuel D. Allison, M.D., 2706 N.E. Clickitat St., Portland, Ore., Director, Division of Venereal Disease Control, Oregon State Board of Health
Helen Baldwin, M.D., Canterbury, Conn., Public Health Officer
Edward B. Bukowski, M.D., C.P.H., 806 Fillmore Ave., Buffalo, N. Y., Assistant Director, Syphilis Control Program, City Health Dept.
Jack A. Crittenden, M.D., Elba, Ala., Health Officer, Coffee County Health Dept.
Samuel S. Farago, M.D., Ph.B., 101 West Broad St., Westerly, R. I., Health Officer
William Y. Garrett, M.D., Eastville, Va., Health Officer, Northampton County Health Dept.
Theodore A. Jost, M.D., City Hall, Mount Vernon, N. Y., Commissioner of Public Health
William L. Lockman, M.D., Julian, Calif., Physician, U. S. Indian Service
L. Archibald MacLean, M.D., Box 180, Red Deer, Alberta, Sask., Canada, Medical Health Officer
Cornelius M. Mills, M.D., C.P.H., 303 State Bldg., San Francisco, Calif., Chief, Crippled

Children's Services, State Dept. of Public Health
Emil E. Palmquist, M.D., 543 East 91 St., Seattle, Wash., Health Officer
Harold H. Whitted, M.D., State Dept. of Public Health, Montgomery, Ala., Acting Assistant Surgeon, Division of Venereal Diseases, U. S. Public Health Service

Laboratory Section

Gladys Anthony, A.B., Box 217, Grand Junction, Colo., Owner and Director, Anthony Clinical Laboratory
Harold E. Brakewood, A.B., National Folding Box Co., New Haven, Conn., Chief Chemist
Elmer F. Chaffee, 1317 Alturas St., Boise, Idaho, Laboratory Technician, Idaho Division of Public Health
William A. Dunlap, M.A., District Laboratory 1, State Board of Health, Parsons, Kans., Bacteriologist in Charge
Jules Freund, M.D., C.P.H., Bureau of Laboratories, New York City Dept. of Health, Otisville, N. Y., Assistant Director
Arthur W. Hayes, Route 1, Box 5753, Sacramento, Calif. Market Milk Specialist, California State Dept. of Agriculture

Maxwell L. Littman, Ph.D., 108 Goodwin Ave., Newark, N. J., Sanitary Chemist and Bacteriologist. Dept. of Water Supplies and Sewage Disposals, New Jersey Agricultural Experiment Station

Mary H. Rankin, B.A., 501 Texas Ave., Austin, Tex., Laboratory Technician, Texas Bureau of Laboratories

Mary E. Tenney, M.A., 1208 South 8 St., Sheboygan, Wis., Supervisor, State Co-operative Laboratory of Hygiene

John L. Wilson, Ph.D., 914 Guardian Bldg., St. Paul, Minn., Research Director, Economics Laboratory, Inc.

Vital Statistics Section

Henry K. Beye, A.B., 2211 Quincy St., Bakersfield, Calif., Statistician, Kern County Dept. of Health

Margaret E. Graff, A.B., 82 Washington Ave., Albany, N. Y., Assistant Statistician, New York State Dept. of Health

Jules V. Quint, B.S., 1 Madison Ave., New York, N. Y., Assistant to Supervisor of Occupation Ratings and Accident Statistics, Metropolitan Life Insurance Co.

Public Health Engineering Section

Charles S. Brown, P. O. Box 684, Chapel Hill, N. C., Trainee Sanitarian, Georgia Dept. of Public Health

Louis H. Herschler, B. of C.E., Plague Laboratory, Kahului, Maui, T. H., Sanitary Engineer

Walter C. Janson, A.B., M.S.P.H., 294 N. Village Ave., Rockville Centre, L. I., N. Y., Student

Clarence R. Jones, B.S.Agr., C.P.H., Harrison County Health Dept., Clarksburg, W. Va., District Milk Inspector

Carl E. Schwob, M.S., 1800 West Fillmore St., Chicago, Ill., Senior Assistant Sanitary Engineer, State Dept. of Public Health

Percy A. Shaw, B.S., in C.E., Manchester Water Works, Manchester, N. H., Engineer Member, State Board of Health

Rodney L. Small, County Health Unit, Lewiston, Idaho, Sanitarian, Idaho North Central Health Unit

Industrial Hygiene Section

Harold W. Ruf, Ph.D., State Office Bldg., Madison, Wis., Industrial Sanitary Engineer, Industrial Hygiene Unit, State Dept. of Health

Food and Nutrition Section

Howard J. Cannon, A.B., 1411 East 60 St., Chicago, Ill., Director, Laboratory of Vitamin Technology

Louis S. Fridericia, M.D., Blegdamsvej 21,

Copenhagen, Denmark, Professor of Public Health, University of Copenhagen

Jean M. Stewart, M.A., Agricultural Extension Service, University of Arizona, Tucson, Ariz., Extension Nutritionist

Child Hygiene Section

Harry L. Clark, M.D., 353 Ocean Ave., Brooklyn, N. Y., Obstetrician and Gynecologist

Alexander A. Cozzalio, D.D.S., 318 First National Bank Bldg., Reno, Nev.

Harry S. Mackler, M.D., 590 West End Ave., New York, N. Y., Pediatrician, Foster Home Bureau, Hebrew Sheltering Guardian Society

Public Health Education Section

Dwight M. Bissell, M.D., C.P.H., Monterey County Hospital, Salinas, Calif., Health Officer and Assistant Medical Director

Mrs. Almeda Chandler, 5 Town Square, Plymouth, Mass., Clerk, Board of Health

Donald K. Freedman, M.D., 522 East 88 St., New York, N. Y., Associated Hospital Service of New York

Wilfred F. Kruse, M.S., 1028 Bonnie Brae, River Forest, Ill., Instructor in Public Health, Concordia Teachers College

Public Health Education Section

Ethel Mealey, M.S., State Board of Health, Portland, Ore., Director of Health Education

Mrs. Geneva F. Rockford, R.N., Memorial Hall, Northampton, Mass., Field Nurse and Executive Secretary, Hampshire County Public Health Assn.

Gerald A. Spencer, M.D., D.P.H., 2135 Seventh Ave., New York, N. Y.

Martha Van Meter, M.A., 583 Broadway, Gary, Ind., Executive Secretary of Lake County Tuberculosis Assn.

Public Health Nursing Section

Alma A. Carlson, Mountain Village, Alaska, Field Nurse, U. S. Office of Indian Affairs

Edith J. Dautremont, R.N., Taholah Indian Agency, Hoquiam, Wash., Field Nurse

Helen F. Dunn, B.S., 1812 K Street, N.W., Washington, D. C., Assistant Director of Nursing, American Red Cross

Nan M. Gallagher, R.N., Kakanak, Alaska, Field Nurse, U. S. Office of Indian Affairs

Margaret C. Joyce, R.N., 85 North Broadway, White Plains, N. Y., Field Secretary, Westchester Tuberculosis and Health Assn.

Mrs. Hope Newell, R.N., 110 West 94 St., New York, N. Y., Maternity Supervisor, Henry Street Visiting Nurse Service

Lillian I. Peterson, R.N., 1419 Schilling St., Chicago Heights, Ill., Public Health Nurse,

Tuberculosis Institute of Chicago and Cook
County

Mary A. Reber, R.N., C.P.H., 266 Blue Lakes
North, Twin Falls, Idaho, Staff Nurse,
South Central District Health Unit
Harriet C. Russell, R.N., Jerome, Idaho, Staff
Nurse, South Central District Health Unit
Eva G. Schwitzer, R.N., 723 Main East, Twin
Falls, Idaho, Staff Nurse, South Central
District Health Unit

Unaffiliated

John Campbell, Board of Health, Hilo,
Hawaii, Junior Sanitary Inspector
Arthur E. O'Neill, D.D.S., P. O. Box 103,
Redwood City, Calif., Chairman, Board of
Health and Welfare, San Mateo County
Max. A. Pleasure, D.D.S., 6250 Saunders St.,
Rego Park, L. I., N. Y., Dentist, New York
City Dept. of Health

DECEASED MEMBERS

Robert L. Frisbie, M.D., Rhineland, Wis.,
Elected Member 1937
Clarence D. Hart, M.D., Savannah, Ga.,
Elected Fellow 1923, Elected Member 1918
Jacob G. Lipman, Ph.D., New Brunswick,
N. J., Elected Member 1915, Elected Fellow
1923
Gustave A. Ootman, M.D., Kelowna, B. C.,
Canada, Elected Member 1935
William H. Park, M.D., New York, N. Y.,
Elected Member 1912, Elected Fellow 1923
Evert G. Routzahn, New York, N. Y.,
Elected Member 1912, Elected Fellow 1923
Charlotte A. Stickney, M.D., St. Paul, Minn.,
Elected Member 1938
Grace Van Doorn, B.A., Milwaukee, Wis.,
Elected Member 1926

A.P.H.A. WORLD'S FAIR EXHIBIT

ADDITIONAL contributors to the exhibit on
Public Health Administration which the
Association is sponsoring at the New York
World's Fair are as follows:

Dr. Marion Shepard
Dr. Garland L. Weidner
Susan M. Wood

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, when keyed, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y., identifying clearly the key number on the envelope.

POSITIONS WANTED

HEALTH OFFICERS

Unusually well qualified and experienced administrator, M.D., Johns Hopkins; M.P.H., Harvard; with broad experience in administering programs of medical care, is available. A404

Physician, M.D., class A medical school; M.S.P.H., University of Michigan, 1939; 10 years' experience in administrative full-time health programs; seeks position in public health administrative position. A373

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; is available as venereal disease control officer. A363

Physician with M.P.H. from Harvard, experienced as epidemiologist and in health administration, also in communicable diseases at state level, seeks responsible position. A392

Physician, M.D., class A medical school; 12 years' full-time public health experience; now employed with state department of health; will consider opening with well organized city or state department in communicable disease division or epidemiology or both. Mid-west preferred. A409

Physician, M.D., Yale; M.S.P.H., Columbia; also short course for health officers, Vanderbilt; good clinical background; one year public health experience; will consider appointment in child health, epidemiology or public health administration. A350

Physician, M.D., Syracuse University; postgraduate studies in bacteriology and immunology, will consider position as health officer or epidemiologist. Has served as director of county health unit, director of industrial hygiene and medical statistics and venereal disease field survey officer. A305

Physician, aged 39; M.D. and Dr.P.H., Yale University; with excellent training in medicine, pediatrics and epidemiology,

now specializing in public health education, will consider appointment in health education or administration. A366

Physician, M.D., Columbia; experienced as county health officer and superintendent of health, seeks position in public health administration or medical executive work. A396

Physician, M.D., Johns Hopkins; M.S.P.H., University of Michigan; experienced in school and city health work; for the past year director of county health department, seeks position as health director of city school system or in health service of a college or university. Will also consider position as epidemiologist or health officer in urban health department. A354

Physician, M.P.H., Harvard, well experienced in city and rural health administration, will consider appointment as district health officer or in city or state health department. A418

HEALTH EDUCATION

Young woman, Ph.D., Columbia University, splendid background of experience in health education, will consider position as director of public health education. H294

Well qualified woman in health education wishes position as health coordinator or health counselor. Has wide experience, and Ph.D. from New York University. H236

Young woman, M.A., Health Education, Teachers College, Columbia University; with splendid international experience, seeks position as director of health education. H369

Young woman, experienced teacher in health education, with M.S. in Public Health and Hygiene from University of Michigan, seeks position as health coordinator. H398

Experienced director of health education, R.N. and college graduate, with excellent references, will consider health education or promotional position. H408

LABORATORY

Experienced laboratory director with background of dairy products manufacture and research in control methods; University of Wisconsin, M.S. and Ph.D., desires administrative position with food manufacturing or processing industry, or association with health department doing routine and research work in food control. L381

Experienced woman bacteriologist, Ph.D., University of Illinois, 1937, wishes position in teaching or research. Excellent bibliography and references. L410

Physician, M.D., Northwestern; Dr.P.H., Johns Hopkins; broad experience in laboratory, teaching and epidemiological fields, will consider temporary position for summer, preferably in parasitology. M293

Capable research worker, Ph.D., trained at University of Southern California and Pasteur Institute, seeks position directing laboratory, in research work or field investigation. Has taught bacteriology, directed state hygiene laboratory and hospital laboratories. L315

Chemist and bacteriologist experienced in water supply, sewage, and public health laboratory work. Five years' ex-

perience. B.S., 1933. Desires work in sanitation or general public health. L412

Bacteriologist and serologist, A.B., University of Wisconsin, at present bacteriologist in state public health laboratory, will consider another position. L416

MISCELLANEOUS

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

Physician, M.D., class A medical school; training in obstetrics and public health. Experienced as director of county health department, teacher of clinical obstetrics and administrator of state maternal and child health program, desires position in public health obstetrics or in maternal and child health administration. C417

Public health engineer, B.S. in Sanitary Engineering, University of California, 1937. Now completing training for C.P.H. in Public Health Engineering, University of California. Well trained in sanitation and other activities, including public health administration, health education, etc. Desires position as sanitary or public health engineer in municipal, county or state health department. E413

Positions Available

SCHOOL NURSE—Public health nurse with degree for interesting position with public schools in town of 65,000; midwest. PH-60, Medical Bureau, Pittsfield Building, Chicago.

CAMP NURSE—Boys' camp; Wisconsin; July and August; preferably school nurse who can take position each summer. PH-61, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH NURSE—City health department; preferably someone with some orthopedic training; considerable traveling. PH-62, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH NURSE—For position of assistant supervisor of nurses, city health department; graduate of scholastic work in public health and field work required; department carries on generalized public health nursing service; midwest; 4 month course in public health nursing and year of public health nursing under supervision re-

quired. PH-63, Medical Bureau, Pittsfield Building, Chicago.

SCHOOL NURSE—School system of small Colorado town; experience essential; \$1,200-\$1,500. PH-64, Medical Bureau, Pittsfield Building, Chicago.

ASSISTANT HEALTH COMMISSIONER—Physician, 35-40, with C.P.H. or M.P.H. and several years' experience; important southern city; vicinity \$5,000. PH-65, Medical Bureau, Pittsfield Building, Chicago.

STUDENT HEALTH PHYSICIAN—Unusual opportunity for young physician desiring to develop along lines public health work, health teaching; possibility attaining M.P.H. at termination of service; 8 hour day, month's vacation; \$2,000, increasing annually; university health service. PH-66, Medical Bureau, Pittsfield Building, Chicago.

Positions Wanted

PUBLIC HEALTH NURSE—B.S. degree; graduate of one of country's leading training schools; postgraduate training in public health and hygiene, state university; for further details, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

BACTERIOLOGIST desires position, preferably in public health laboratories; B.A., eastern school; C.P.H. and Ph.D. (bacteriology), Yale University; has done considerable research; 4 years, bacteriologist and research technician, public health laboratories; for further details, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

HEALTH EDUCATOR—Graduate nurse and B.S. degrees; social service certificate; 3 years' experience in social service; 4 years, industrial nursing; 10 years, director of a health council; for further details, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH PHYSICIAN desires connection; M.D., Virginia; several years' successful private practice; 10 years' public health work during which time he has been promoted continuously, excellent reason for relocating; for further details please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

NEWS FROM THE FIELD

WHITE HOUSE CONFERENCE ON CHILDREN IN A DEMOCRACY

THE President of the United States has appointed the Honorable Frances Perkins, Secretary of Labor, as Chairman of a White House Conference on Children in a Democracy. Following preliminary work by an informal committee and conference with the President, a Planning Committee was appointed by the Chairman of the Conference to be responsible for its organization and work. This Planning Committee met in Washington on March 14 and planned a meeting on April 26 at the White House for the general organization of the Conference.

In order to provide for a wide representation of professional and lay interests and to secure representation from each state, a committee has been selected of about five hundred with the aim that this might be a working conference.

The first meeting was held in Washington on April 26 at the White House. The speakers included the President of the United States, Mrs. Franklin D. Roosevelt, The Honorable Frances Perkins, Secretary of Labor, Right Rev. Mgr. Robert F. Keegan of New York, the Executive Director of the Catholic Charities of the Archdiocese of New York, and Homer Folks of New York, Secretary of the State Charities Aid Association.

This Conference, which is the fourth White House Conference on this general subject, will hold its final sessions early in 1940—ten years after the last similar Conference.

Katharine F. Lenroot, Executive Secretary of the Conference, has announced that the total membership is now 585, including representatives of every state and of Alaska, Hawaii, Puerto Rico, and the District of

Columbia. Attendance at the initial sessions included 410 persons, representing all but two states and Alaska.

Among subjects to be considered by the Conference will be the following:

1. Children and Democracy

A consideration of the primary objectives of a democratic society in relation to children, the institutions through which a democratic society works for the attainment of these objectives, and the ways in which democracy, through its various institutions, can present to children and youth an intelligent understanding of its goals and ideals.

2. Children and Life in the United States Today

A consideration of the needs of children under present-day conditions in the United States, the extent to which they are met, and the ways in which they may be supplied more fully.

3. Children and the Future of America

A summary of the major issues developed under the previous headings, with recommendations which may lead to more complete realization of the objectives of democracy for children and the development in children of capacities for democratic living.

Among those in attendance at the first session were more than 60 Fellows and members of the American Public Health Association.

PUBLIC HEALTH ASSOCIATION OF NEW YORK CITY

THE Third Annual Meeting of the Public Health Association of New York City was held at the Hotel McAlpin May 18.

Speakers at the session on chemotherapy with respect to syphilis and other communicable diseases included Dr. Louise Pearce, of the Rockefeller Institute, and Dr. Reuben Ottenberg, of Mt. Sinai Hospital. On the subject of problems in connection with plans for furnishing medical service to the middle classes of the United States, speakers were: Dr. Michael M. Davis,

Dr. Leo Price, Dr. Haven Emerson, Dr. George T. Palmer, and Bernard S. Coleman.

At the Annual Dinner Meeting, Dr. Louis I. Dublin spoke on the Museum of Health, now included in the Hall of Man, of the Medicine and Public Health Building at the New York World's Fair. The guest of honor at the dinner was Sir William McLean, a member of the British Commission to the World's Fair.

Officers for 1938 were reelected as follows:

President, Hazel Corbin

First Vice-President, Dr. Arthur I. Blau

Second Vice-President, Dr. George T. Palmer

Secretary-Treasurer, Frank Kiernan

HARVARD SYMPOSIUM ON VIRUS AND RICKETTSIAL DISEASES

IT has been announced, by Dr. C. K. Drinker, Dean of the Harvard School of Public Health, Harvard University, Boston, Mass., that registration for the short course of lectures, clinics and demonstrations on the virus and rickettsial diseases—to be given June 12-17—is still open within the capacity of the course.

An outline of this event was carried in the February issue of the *Journal*, page 193.

SMALLPOX IN NEW YORK STATE

AN outbreak of 13 cases of smallpox in the town of Ripley, Chautauqua County, N. Y., with at least 600 others known to have been exposed to the disease, was announced by Dr. Edward S. Godfrey, Jr., State Commissioner of Health. The Ripley outbreak involves 11 adults and 2 children of 6 families. The first case, occurring April 1, was that of a truck driver who traveled between Syracuse, N. Y., and Cleveland, Ohio. The last case occurred on May 15.

This is the second outbreak in the State within the past three months.

BOVINE MASTITIS STREPTOCOCCI CLASSIFICATIONS

AN international study of the streptococci associated with bovine mastitis has been announced in order to arrive at a more uniform classification. Briefly, it has been decided to ask those who are studying mastitis to reexamine their cultures (1) by means of a group B standard serum which will be issued, and (2) by certain relatively simple cultural and biochemical methods. Mimeographed copies of suggested methods and the group B serum will be sent to anyone interested.

Persons resident on the American continent and in Japan should write to Dr. R. B. Little, Rockefeller Institute, Princeton, New Jersey; while those in Europe and the British Empire should communicate with Dr. F. C. Minett, Royal Veterinary College, Camden Town, London, N.W.1, England.

PHARMACOPOEIA REVISION

A CALL for a Convention for the Revision of the Pharmacopoeia of the United States, to be held in Washington beginning May 14, 1940, has been issued by Walter A. Bastedo, M.D., of New York, President of the United States Pharmacopoeial Convention.

Dr. Bastedo points out that, under the present Federal Food, Drug and Cosmetic Act, the standards of strength, quality and purity laid down in the Pharmacopoeia for the drugs and preparations that it recognizes automatically become the legal standards for these preparations.

BALTIMORE RAT PROOFING ORDINANCE

AN ordinance has been passed in Baltimore, Md., as part of a rat control program providing for the rat-proofing of all buildings hereafter erected in the city for the protection of public health and to prevent the introduction or spread of rat-borne diseases.

NEW ENGLAND HEALTH INSTITUTE

STATE Departments of Health, State Departments of Education and State Tuberculosis Associations for the six New England states joined with the New England Health Association in putting on a New England Health Education Institute, April 21 and 22, at the Massachusetts Institute of Technology. This is the first time that such agencies have combined in organizing a special professional program in the Health Education Field. Over 600 persons registered for the Institute.

The costs of the Institute were underwritten in part by certain of the participating agencies, but the \$1,200 secured from the \$2 registration fee made the project practically self-supporting.

The meetings opened with a General Session on Friday morning with a discussion of the "Underlying Psychology for Motivating Health Behavior." On Friday afternoon the practical application of these principles was considered as they apply to the elementary school level, the secondary school level, the college level, and the adult level.

On Saturday 7 separate Sections were held. These sessions dealt with "Educational Aspects of Medical, Dental and Nursing Services in Schools," "Evaluation of Programs," "Types of Measurement in Physical Education Programs," "Problems in Health Service and Health Curriculum in Colleges," "Publicity Methods in Public Health Education," "Health Education in Maternal and Child Welfare," and "Rural Health Education."

A general open meeting on Friday evening was addressed by Dr. Henry F. Vaughan, Dr. H. D. Chope and Dr. Dorothy Nyswander. A Friday luncheon meeting was addressed by Dr. Channing Frothingham, President of the Massachusetts Medical Society, and a Saturday luncheon was addressed by Dr. Howard W. Haggard of Yale

University. Seventy-one speakers and discussion leaders participated in the 2 day program.

The Institute was planned and conducted by an Organizing Committee under the chairmanship of Professor C. E. Turner of the Massachusetts Institute of Technology, with Arthur J. Strawson of the Massachusetts Tuberculosis League as Executive Secretary. The members of the Organizing Committee consisted of the officers of the New England Health Education Associations, the State Commissioners of Health, the State Commissioners of Education, and the Executive Officers of the State Tuberculosis Associations or their special representatives. There were sub-committees on arrangements, membership, coöperating agencies, exhibits, finance, program, publicity, and registration.

Any member of the American Public Health Association who is interested in further details of organization may secure a copy of the program by writing to Professor C. E. Turner, at the Massachusetts Institute of Technology, Cambridge.

HENRY STREET VISITING NURSE SERVICE
HAS NEW HEADQUARTERS

THE Henry Street Visiting Nurse Service is now located at its new address, 262 Madison Avenue, New York City.

This new building, which will be dedicated in the autumn, replaces the property given to the Nursing Service in 1925 by Mrs. Jacob H. Schiff, located at 99 Park Avenue. Two years ago this building, which for fifteen years had housed the administrative staff, was purchased by the City of New York for a Court House site, making possible another building at the present address, all expenses in the acquisition of which have been defrayed from the proceeds of the sale of 99 Park Avenue.

AMERICAN CONGRESS ON OBSTETRICS PROGRAM

THE program for the American Congress on Obstetrics and Gynecology to be held in Cleveland, Ohio, September 11-15, 1939, has been announced. Copies may be obtained from the Conference office, The Annex, 650 Rush Street, Chicago.

The first day, sessions will be given over to considerations of Public Health and Maternity Care, the second day to Providing Continuity of Maternal Care in the Rural Areas, the third day to Federal and State Programs in Maternal Care, the fourth to the problems of Economics, and the fifth to the problems bearing on Education.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

THE Summer Meeting of the Section on Medical Sciences of the American Association for the Advancement of Science will be held in collaboration with the American Neisserian Medical Society, in Milwaukee, Wis., July 19-24, 1939.

There will be four scientific sessions devoted respectively to The Biology of the Gonococcus, The Diagnosis of Gonococcal Infection, Therapy and Control, and Sulfanilamide and Related Compounds.

SOME NOTABLE RETIREMENTS

"At this time of year it is always necessary to bid farewell, in their official capacity, to some senior members of the public health service. This year brings some especially noteworthy partings. . . .

The same applies to our other Past-President, Dr. Charles Porter, who gave up his post at St. Marylebone on March 15th, after nearly 30 years of service to his borough. Dr. Porter has been so eminent a figure in the work of the Society both as a Branch Secretary, as a member of the Council, as

President, and last, but by no means least, as Honorary Editor of *Public Health* for ten years, until 1936, that any tribute we pay would fall short of adequacy. We feel sure that he will continue to make himself felt in the world of public health and that his activity will remain unabated. . . ."—Editorial, *Public Health* (London), April, 1939.

PERSONALS

Central States

ERVIN J. BRENNER, M.D.,† of Manistique, Mich., Director of the Alger-Schoolcraft Health Department, has been appointed to take charge of the new health service in Schoolcraft County, providing medical, nursing, and hospital care for expectant mothers who would not otherwise be able to secure such care. This service has been organized by the Michigan State Department of Health with Social Security Funds, and will be operated with the coöperation of local physicians.

DR. ALEXANDER M. CAMPBELL, of Grand Rapids, Mich., has been appointed full time Consultant to the Bureau of Maternal and Child Health of the Michigan State Department of Health, Lansing. He will carry on a program jointly sponsored by the state medical society, the W. K. Kellogg Foundation, the University of Michigan, and the State Department of Health, working with the maternal health committees of the county medical societies in the state.

DR. CLAUDE DOLLENS, of Oolitic, Ind., has been appointed Health Officer of Lawrence County, succeeding the late Dr. JOHN S. WOOLERY, of Bedford.

DR. LOUIS J. FREDERICK has been appointed Health Commissioner of

† Member A.P.H.A.

Joliet, Ill., succeeding the late DR. EDWARD J. HIGGINS.

THOMAS E. GIBSON, M.D.,† of Paw Paw, Mich., formerly Director of the Van Buren County Health Department, has been appointed Director of the Venereal Disease Division of the Michigan State Department of Health, Lansing.

ROBERT B. HARKNESS, M.D.,† of Lansing, Mich., Director of the Barry County Health Department, was elected President of the State Council of Health recently, succeeding the late URA G. RICKERT, D.D.S., of Ann Arbor.

DR. WILLIAM HARRY HUTTO † has been appointed Health Officer of Kokomo, Ind., and Secretary of the City Board of Health, succeeding DR. WILLIAM J. MARTIN.†

DR. THOMAS J. MCKEAN, of Montpelier, Ind., has been named Health Officer of Blackford County, to succeed the late DR. ELMER D. SHADDAY.

ARTHUR W. NEWITT, M.D.,† who has been Chief of the Division of Tuberculosis of the Michigan State Department of Health, Lansing, has been appointed Acting Director of the Division of Epidemiology.

DR. EXIE E. WELSCH, who has been directing the mental hygiene program of the Bureau of Maternal and Child Health of the Indiana State Board of Health, has been transferred to the Bureau of Mental Care of the State Department of Public Welfare. She will assist DR. GEORGE C. STEVENS, Director, Division of Medical Care, in organizing the clinics.

Eastern States

LETHA S. ALLEN, R.N.,† formerly Director of the Public Health Nursing Organization of Eastchester, N. Y., has recently been appointed by the Nursing Bureau of Man-

hattan and Bronx to develop a placement and vocational guidance service for public health nurses. This Bureau, which has been working in the institutional field since 1933, is now widening its scope, and offering assistance both to public health nurses and the employing agencies in their problems of placement. It has the tentative approval of the National Organization for Public Health Nursing.

MURIEL F. BLISS, C.P.H.,† who has recently completed a course in public health at Yale University, has accepted a position in health education under the Nassau County, N. Y., Cancer Committee, Mineola, Long Island.

DR. SAMUEL J. DICKEY, of West Chester, Pa., Health Officer of Chester County, has been appointed Director of the Division of Tuberculosis in the Pennsylvania State Department of Health.

DR. FRANCIS H. GLAZEBROOK, Medical Director since 1931 of the Medical Department of the New York Stock Exchange, New York, N. Y., has retired. The Department was discontinued as an Exchange activity on April 1.

DR. CHARLES F. GORMLY, of Providence, R. I., has been appointed Chairman of a Committee on Industrial Health of the Rhode Island Medical Society.

SAMUEL MCCLINTOCK HAMILL, M.D.,† of Philadelphia, Pa., was awarded the Dr. I. P. Strittmatter Gold Medal by the Philadelphia County Medical Society on April 12. Dr. Hamill, who has practised in Philadelphia since 1890, has been active in child welfare work for many years.

DR. HAROLD A. HOWARD has been appointed Health Officer of Wethersfield, Conn., to succeed the late DR. EDWARD G. FOX.

DR. ROBERT S. MILLEN, of Westbury,

† Member A.P.H.A.

N. Y., is taking over the quarters of the discontinued Medical Department of the New York Stock Exchange, New York, N. Y., and will operate a clinic there on his own behalf.

WOODBRIDGE E. MORRIS, M.D.,[†] Dover, Del., has resigned as Director of the Division of Maternal and Child Health and of the Crippled Children's Service of the Delaware State Board of Health as of May 1, to accept the position of Director of the Birth Control Federation of America, with headquarters in New York, N. Y. The Federation was formed in January, 1939, by a merger of the American Birth Control League and the Birth Control Clinical Research Bureau.

DR. CYRUS E. PENDLETON has been appointed Health Officer of Colchester, Conn., to succeed the late EDWARD J. HOWLAND, M.D.[†]

DR. JOHN M. RENEHAN has been appointed Health Officer of Ansonia, Conn., to succeed Dr. LOUIS HOWARD WILMOT.

DR. GEORGE E. ROCH has been appointed Health Officer of Willimantic, Conn., to succeed Dr. REUBEN ROTHBLATT.

LESTER A. ROUND, PH.D., has been appointed Director of the Department of Public Health and State Registrar of Vital Statistics for Rhode Island, succeeding EDWARD A. McLAUGHLIN, M.D.[†]

Southern States

DR. JOHN B. FLOYD, of Richmond, Ky., has been appointed Director of the newly created Bureau of Medical Service of the Kentucky State Department of Health, established to assist the medical profession of the state in providing medical service for the indigent and medically indigent.

DR. JOHN M. HOOPER, of Floydada, Tex., formerly of Pampa, has been appointed Director of Public Health for District No. 1, which includes 60 counties in the Panhandle and South Plains area.

DR. FRANCIS T. ISBELL, of Eastland, Tex., has been appointed Health Officer of Eastland County.

DR. ALBERT G. LEROY, of Atlanta, Ga., has been appointed Commissioner of Health of Toombs County.

COLONEL JAMES CARRE MAGEE, Medical Corps, U. S. Army, at present Executive Officer of the Walter Reed General Hospital, Washington, D. C., has been appointed Surgeon General of the U. S. Army with the rank of Major General. He succeeds MAJOR GENERAL CHARLES R. REYNOLDS, whose term as Surgeon General expired May 31. Colonel Magee is a veteran of 32 years' service in the Medical Corps; and is a World War veteran, having served in the A.E.F. during the entire period of American participation in the war.

Western States

DR. JAMES V. FOLEY has been appointed Health Officer of Bannock County, Ida., succeeding GEORGE H. BISCHOFF, M.D.[†]

HOWARD L. McMARTIN, M.D.,[†] of Boise, Ida., formerly Director of the Division of Maternal and Child Health and Crippled Children, of the Idaho State Department of Public Welfare, has been appointed Director of the Division of Public Health of the Department.

DR. JOSEPH L. RICHARDS, of Polson, Mont., has been reappointed County Physician and Secretary of the Board of Health of Lake County.

COURTNEY M. SMITH, M.D.,[†] of Oregon City, Ore., has resigned as Health Officer of Clackamas County, to become Assistant Health Officer of Portland.

[†] Member A.P.H.A.

State Procedures for Communicable Disease Control*

HAVEN EMERSON, M.D., F.A.P.H.A.
New York, N. Y.

DURING the meeting of the American Public Health Association in Kansas City in October, 1938, there was a session of the Committee on Evaluation of Administrative Practices at which comment was made upon what appeared to be unnecessarily long periods of isolation required for some of the communicable diseases in certain cities. The health officer of one city referred to explained that while he believed that his isolation regulations were inconsistent with the known periods of communicability of some of the diseases, he had no choice but to enforce them as they were so specified in the state sanitary code.

A request was made that the Committee on Evaluation study the current state procedures for Communicable Disease Control to learn the extent of their variance from or agreement with those proposed by the Committee on Control of Communicable Diseases, and

officially adopted by the American Public Health Association and endorsed and published by the U. S. Public Health Service in three successive editions of 1916, 1926, and 1935. (*Reprint 1697*).

Your invitation to me to take part in your program is, I presume, to hear a report upon this study which has been made from the official documents courteously supplied from the offices of the various officers of state, insular, and territorial health services.

It must be admitted that there is no intrinsic merit in the uniformity of regulations, *per se*, nor is standardization of procedures for the sake of uniformity of practice alone always justified. However, when personal liberty is restricted in the interest of the prevention of communicable disease, under the authority of sanitary laws, ordinances, rules and regulations, it is a matter of official concern and may at any time become a matter of legal intervention, if it appears that the periods of isolation imposed upon infected persons, and periods of quarantine required of exposed susceptible persons are in-

* Read before the Conference of State and Provincial Health Authorities of North America in Washington, D. C., April 22, 1939.

consistent with the known periods of incubation and communicability of the disease in question. Furthermore, the credit of a public service presumably conducted on the basis of exact knowledge of the natural history of disease is at stake, and may easily be brought into disrepute and the reasonable disregard of both the laity and the medical profession, when within neighboring health jurisdictions the same disease is subject to widely varying official restrictions.

Of the 44 communicable diseases of which notification to local or state health department is usually obligatory in the states and other political subdivisions of the United States, I have selected 12 as illustrative of the major factors involved in administrative control.

It can be easily seen that if for each disease and each of the 56 political units under study, every stage of control from notification to terminal disinfection, immunization of susceptibles and discovery of the source or sources of infection were analyzed, the presentation of any useful observations would require an encyclopedic monograph. Any such meticulous and detailed analysis appears to be quite unnecessary in view of the ample evidence of lack of uniform agreement between legal requirement and scientific fact offered in the restricted field of the present study.

I have therefore selected from among the 15 items tabulated for each disease and each state only a few, including the incubation period, period of communicability, isolation and quarantine periods, for our present discussion.

It is customary although by no means universal practice for a state department of health to present in printed form for guidance of its own professional staff and for the convenience and education of physicians, sanitarians, and nurses in official and voluntary health agencies, and for medical institutions

and agencies and practitioners of medicine within the state, a statement of procedures and the phenomena of disease upon which these are based at least for the commoner notifiable diseases.

Among the essential facts to be included in any such official publication are the lengths of the incubation and communicable stages of the disease upon which the isolation and quarantine requirements are based, as well as a precise definition of the duration of and conditions of release from isolation and quarantine.

While much remains to be determined by further and more exact definition of these periods even in diseases with which we have long been familiar, there is sufficiently exact information, officially accepted by the American Public Health Association and the U. S. Public Health Service, and available at nominal cost from the Superintendent of Documents, so that there is no excuse, except a greater accuracy of knowledge on the part of the state health officer or board of health, for any serious discrepancies in the procedures recommended. Taking the requirements applicable to these 12 diseases as convenient examples I can express in relatively brief form the range of variance in the practices as provided for (I cannot say in all instances observed) in the several states. In using the term states I include for convenience, Washington, D. C., the Canal Zone, Hawaii, Alaska, Philippine Islands, Virgin Islands, and Puerto Rico.

1. CHICKEN POX

Chicken pox has a recognized incubation period of from 14 to 21 days and a period of communicability of not more than 6 days from the appearance of the first crop of vesicles and certainly not more than 10 days, regardless of the disappearance of primary or secondary scabs and healing of the

lesions on skin and mucous membranes.

Seven states do not require the reporting of chicken pox. Twenty-five states either fail to declare the incubation period or state it to be 14 to 21 days. A few states make a routine practice of verifying diagnosis in cases reported in persons over 15 years of age, and in 1 state for persons over 12.

Isolation is required by 17 states "until the scabs disappear."

Twenty-two states fix the period of isolation at anywhere from 6 to 21 days. Thirteen of these specify that in any event scabs must have disappeared prior to release. Only 2 states definitely commit themselves to an isolation period of 6 to 10 days from the appearance of the first vesicle.

While there is no known benefit to the patient, to susceptible contacts, or to the public at large, from quarantining susceptibles exposed to chicken pox, there are 7 states which require quarantine of adult contacts, and 15 which require quarantine of child contacts. Five other states leave quarantine to the discretion of the local health officer in the case of adult contacts and 4 in the case of children. In 1 state daily inspection of contacts for 21 days from last exposure to chicken pox is required.

In 16 states concurrent and terminal disinfection is called for, in 11 concurrent alone, and in 2 terminal alone.

2. DIPHTHERIA

Diphtheria has a recognized usual period of incubation of 2 to 5 days. The period of communicability, while determinable with considerable precision by culture methods, is usually less than 2 weeks, rarely over 4, and only in exceptional instances a convalescent carrier state continues for 2 to 6 months.

The questions we are mainly concerned with are: When should we begin with cultures for release from isolation? When should we release from isolation if culture control cannot be

had? At what time after the onset of the disease should we apply the virulence test to determine whether a convalescent carrier need be further isolated?

In 29 states the incubation period is officially declared to be not more than 7 days (almost all specify 2 to 7 days); 19 states make no declaration on this point.

Thirty-eight states require for release from isolation 2 negative cultures from nose and throat with at least a 24 hour interval between. One state requires only one negative nose and throat culture. Among the states requiring 2 negative cultures for release, 24 specify the time at which the first culture may be taken, from 7 to 21 days after onset of the disease.

A virulence test is called for in the regulations of 22 states, the time when this is first to be applied varying from 2 weeks to 6 weeks after onset of the disease. In 4 states the time when the virulence test is to be made is not specified.

Quarantine procedures must be analyzed according to the status of the contacts, *i.e.*, adults or children, susceptible or not, for each of which classes of contacts there are various procedures in the several states.

Eleven states do not isolate adult contacts except food handlers or those in occupational relation to children. Twenty-six states release adults on one or two negative cultures. One state quarantines all adult contacts until the death or recovery of the patient. One requires food handlers to live elsewhere if they return to their work when they have had two negative cultures.

For immune children 8 states require quarantine, 4 require negative Schick test before release; 28 require negative cultures before release; 6 states leave all quarantine of adults and children to the discretion of the health officer.

For susceptible children 10 states re-

quire passive immunization or a Schick test; 17 release a child on a negative culture; 9 require absolute quarantine; 1 requires quarantine up to 7 days after release of the patient.

Two states require fumigation of upholstery and 1 requires destruction of all articles exposed to patients' discharges which cannot be sterilized.

3. DYSENTERY (AMEBIC)

In amebic dysentery, neither isolation of the patient, nor quarantine of contacts is recommended.

The basis of release from isolation which is commonly required varies as follows: 7 states release from isolation only on several negative stool findings at various intervals; 1 state requires 3 negatives at 24 hour intervals, and then monthly for 4 months, and thereafter once every 6 months; 1 holds the patient for 5 days and releases on repeated negative stool specimens: 1 releases on 2 negative specimens with a week's interval; 1 releases on 3 negative specimens with a week's interval; 3 on 2 negatives with a day's interval. In some instances these regulations apply only to sick food handlers, in others to all patients.

4. DYSENTERY (BACILLARY)

The recommended procedure is isolation during the period of communicability, which is believed to be while the fever lasts and the infecting organism continues to appear in the bowel discharges. This may be as long as 4 weeks, and may continue into a carrier state. Rigid precautions by attendants are advised and quarantine of contacts is not recommended. An incubation period of 2 to 7 days is recognized.

Fourteen states declare the incubation period to be 2 to 7 days, the others make no mention of this in their regulations.

Isolation is required by 2 states for 10 days after the patient's temperature

is normal; 7 states release after repeated negative stools following normal temperature; 2 release after 3 to 4 weeks. Eight states release on negative stool findings specified as to number and intervals, *viz.*, 3 require 3 negative stools with one day intervals; 3 require 2 negatives with one day interval; one requires 4 negatives at 5 day intervals; one requires 2 negatives after a 4 week isolation period.

No state requires quarantine of contacts.

5. RUBELLA—GERMAN MEASLES

The recognized incubation period is 14 to 21 days, usually 16. The period of communicability is from the onset of catarrhal symptoms for at least 4 days but not more than 7 days. Isolation of patients is rarely practicable but it is recommended for the presumed period of communicability. Quarantine of contacts is not recommended.

Reporting is required by all but 5 of the states. The incubation period is declared by 24 states, all but 2 adopting the period 14 to 21 days, while 1 uses a 14 day period, and 1 a 10 to 21 day period. Twenty-eight states make no mention of the incubation period in the regulations.

Isolation for the recommended period of 4 to 7 days is required by 28 states, with 4 states requiring 8 days, and 1, 4 days from appearance of the rash. Of the other states 16 mention no isolation period, and 3 leave it to the discretion of the attending physician or health officer; 1 holds the patient for 5 days after the disappearance of the rash; 1 holds for 10 days from onset; 1, 16 days; and 1, 21 days.

Quarantine of susceptible children is required by 9 states; in 5 states for 14 days after exposure; in 1 for a period from the 10th to 22nd day after exposure; in 2 for 21 days from exposure and in one for 14 days after a 10 day interval since exposure.

6. MENINGOCOCCUS MENINGITIS

The incubation period is recognized as being 2 to 10 days, commonly 7, and the period of communicability during the clinical course and until the infecting organism is not found in nose and mouth secretions, usually 2 weeks. Quarantine of contacts is not recommended.

All but 4 states require notification of the disease. Twenty-eight states do not mention the incubation period. Twenty-one states declare it to be 2 to 10 days, while 1 state gives it as 16.

Isolation of the patient is terminated on the basis of negative cultures, usually specified to be taken after an interval of days after the onset of the disease by 14 states, and without culture by 17 states. Release is at the discretion of the health officer in 4, and is not specified by 9 states. Three negative cultures are required by 4 states, with 5 day intervals or less the first taken 2 to 3 weeks after onset. One state requires isolation to last until recovery, death, or transfer of the patient.

Quarantine of contacts is not required by 8 states, and its duration is not specified by 6 states. It is required that all contacts be held at the discretion of the health officer in 9 states. Contacts are released after 14 days (in two instances after 10 days) on negative cultures. Contacts who remain at home are released in 1 state 1 week after the patient is isolated, and in 13 states are held for a 2 week incubation period, and in 2 states for a 10 day period.

7. TYPHOID FEVER

The accepted period of incubation is 7 to 38 days, usually 7 to 14. The period of communicability is from the appearance of prodromal symptoms until the discharges are free from the infecting organism.

The incubation period is not speci-

fied in 16 states. It is declared to be 7 to 14 days by 3 states; 7 to 24 days by 1 state; 1 to 21 days by 1 state; 7 to 21 days by 2 states; 7 to 23 days by 11 states; 14 to 21 days by 1 state; 7 to 16 days by 1 state; 14 days by 1 state; up to 30 days by 1 state.

Release from isolation is neither required nor referred to by 7 states. Release on the basis of negative cultures of feces and urine is required by 34 states of which 14 do not specify the number or interval between specimens, nor the time when the first specimen is to be taken. The practice recommended, *i.e.*, release after 2 negative cultures from urine and stools taken 24 hours apart, is specified by 5 states. Release is permitted after 3 negative cultures at 24 hour intervals by 2 states; 2 specimens 1 week apart by 1 state; 2 specimens 5 days apart in 1 state; 2 specimens 7 days apart in 4 states; 3 specimens at 1 week intervals in 1 state; 2 negative specimens 3 weeks apart, the first taken 10 days after clinical recovery in 1 state, 3 negative specimens at 4 day intervals in 1 state. The time for taking the first specimens varies from 6 to 10 days after the patient's temperature returns to normal or there is clinical recovery.

In 1 state release follows 7 days of normal temperature without release cultures.

8. MEASLES

The accepted facts about measles are that the incubation period is 8 to 10 days from exposure until the onset of fever, or 12 to 14 days from exposure to appearance of the rash, rarely as long as 18 days.

The period of communicability begins with the catarrhal symptoms and lasts until abnormal secretions of mucous membranes cease; from 4 days before to 5 days after appearance of rash.

Isolation is recommended during the period of communicability.

Exclusion of exposed susceptible children and teachers from school for 14 days from last exposure may be justifiable. With date of a single exposure known, an exposed susceptible school child may attend school for the first 7 days of the incubation period.

In 10 states the regulations are consistent with the above facts in all essentials. The incubation period is not specified in 19 states; is given as 7 to 14 days in 1 state; 7 to 18 days in 3; 6 to 18 days in 1; 8 to 21 days in 2; 10 to 14 days in 1; 1 to 14 days in 1; 14 days in 5 states.

The isolation period is consistent with the facts in 13 states; is required for 14 days after notification in 1 state; 10 days in 3; 7 days in 6; 5 days after disappearance of symptoms in 5; 7 days after disappearance of symptoms in 7; 8 days after disappearance of symptoms in 1; there is no specification in 3; and the duration of isolation is at the discretion of the health officer in 4.

Quarantine: for adults there are no restrictions in 9 states; 14 days of quarantine are required in 13 states of which 6 specify school teachers; the quarantine periods are at the discretion of the health officer in 7 states.

For children there are no restrictions in 2 states; quarantine is required for 14 days from exposure in 22 states; for 7 to 17 days in 2 states; at the discretion of the health officer in 4 states.

9. MUMPS

The accepted incubation period for mumps is 12 to 26 days, most common 18 days, and 21 days not uncommon. Communicability is assumed to be from onset until the parotid gland has returned to its normal size.

Twelve states have procedures essentially consistent with the accepted facts.

Six states do not require reporting; 39 do.

The incubation period is declared to

be 12 days in 1 state; 14 days in 1; 4 to 30 days in 4 states; not less than 21 days in 1; is not specified in 18.

Isolation: In 22 states children are isolated and excluded from school while in the communicable stage, although none of these states defines the period. In 4 states isolation is required for 2 to 7 days; in 1 state for 10 days; in 1 state 3 weeks from onset; in 1 until recovery; in 2 states 2 weeks from onset and 1 week after swelling of parotid has disappeared.

Quarantine: Most states do not require quarantine of exposed susceptibles. In 4 states quarantine is at the discretion of the health officer; in 7 states it applies to susceptible children for 21 days, with or without daily inspection of the child.

10. SCARLET FEVER

The accepted facts regarding scarlet fever are, that the incubation period is 2 to 7 days, usually 3 to 4, and a period of communicability usually 3 weeks from the onset and until abnormal discharges have ceased and open sores or wounds have healed, regardless of stage or extent of the desquamation.

Fourteen states accept the facts as to length of the incubation period; 2 states specify 2 to 10 days; 1, 10 days; 4 specify 3 to 4 days; 1, 14 days; 12 do not specify duration.

The isolation period required in 25 states is 21 days; in 8 states it is 28 days; in 1 state 14 days; in 1 state 30 days; in 1 state until complete recovery; in 3 states at the discretion of the health officer; in 12 states it is not specified.

Quarantine is as recommended in 29 states, *i.e.*, exclusion of exposed school teachers and children from school, and food handlers from their occupation, for 7 days from last exposure (6 release earlier on negative Dick test); 8 quarantine at the discretion of the

health officer; 4 do not quarantine adults if the patient is isolated; 4 maintain quarantine of members of the household for the duration of the patient's illness.

11. POLIOMYELITIS

An incubation period of 7 to 14 days is accepted as common. The period of communicability is not definitely known, but is believed to include the latter part of the incubation period and extend after onset of the disease for a week or two and possibly much longer. Tracing of a case to a previous case is rare.

In one state the disease is not reportable.

An incubation period of 7 to 14 days is so defined by 10 states; is specified to be 6 to 21 days by 1 state; 3 to 10 or 14 days by 5 states; 2 to 3 days by 2 states; 10 days by 1; 14 days by 1; and is not mentioned by 17 states.

Isolation is required for 2 weeks from onset by 15 states; 3 weeks by 18 states; at the discretion of the health officer by 3 states; no duration is specified by 4 states.

Quarantine of adults and immune or susceptible children is required as recommended by 17 states; quarantine of adult wage earners is not required if the patient is isolated, by 4 states; is required of exposed adults in contact with children or food handlers for 21 days in 4 states; release from quarantine is permitted after disinfection and removal to other residence by 1 state.

For immune children quarantine is not required if they are removed from the household and public places in 3 states; is required for 10 days in 1 state; for 21 days in 5 states; at the discretion of the health officer in 5 states.

For susceptible children: quarantine is not required if they are removed to a household where there are no other

children in 2 states; for 10 days in 1 state; for 21 days in 5 states; at the discretion of the health officer in 6 states.

Two states require gaseous disinfection at termination of the case.

12. PERTUSSIS

The accepted incubation period is commonly 7 days, almost uniformly within 10 days, and not exceeding 16 days; the period of communicability is believed to be from the beginning of the catarrhal stage for 7 to 14 days until 3 weeks after the development of the characteristic whoop.

The incubation period as stated above is accepted by 15 states; is specified to be 10 days by 1 state; 14 days by 2 states; 16 days by 1 state; 14 to 21 days by 2 states; 4 to 14 by 4 states; and is not specified by 11 states.

All states require isolation of the patient; 6 for the period of communicability; 1 for 1 week after onset of the whoop; 2 for 2 weeks from the whoop; 6 states for 3 weeks; 6 states at discretion of the health officer; and 3 for an unspecified duration.

Quarantine of exposed susceptible children is required as recommended for 10 days after last exposure by 11 states; for 14 days by 1 state; for 16 days by 1 state; at the discretion of the health officer by 8 states; during the illness of the patient by 3 states; only for children in institutions in 1 state; for an unspecified duration by 4 states.

One state requires terminal fumigation.

COMMENT

The inconsistencies between reasonably exact experience or observation of incubation and communicable periods of these notifiable diseases and much of the regulation of isolation and quarantine as implied or specified in the publications of state health authorities,

and in the main obligatory upon the respective subordinate health jurisdictions of the states, appear to me to be so considerable in number and degree as to justify your attention.

In spite of these evidences of somewhat irresponsible exercise of the powers of state health authorities in this, the oldest field of preventive medicine, a field full of triumphs and general progress, the present status of communicable disease control is encouraging. Still greater success, with less annoyance to the patient, his family, and the public can probably be achieved if administrative requirements and practice are brought more nearly into agreement with our knowledge of the natural history of these diseases.

Among the multitude of obligations, which should be met by state health authorities in the traditional fields of their authorized functions, namely, to do their own work with approximate

scientific accuracy, before they attempt the difficult and intricate functions of organized care of general medical and surgical illnesses, are those which involve the control of communicable diseases.

It seems to me that the best way to earn merit and the confidence and support of the public for essential health functions is to do the duties now required by law so well that no reasonable criticism from the public or the medical profession can be brought against you.

Rather than to encourage the exercise of persuasion and publicity and politics to have new functions and extensive new funds and duties added to you, for which in the main you lack essential experience and professional qualifications, I urge you to serve in the best possible way with your present resources those functions which no one else can carry on under the law, or is so well prepared for as you are.

The Selenium Problem and Its Relationship to Public Health*

IRA A. MANVILLE, M.D., Ph.D., F.A.P.H.A.

Nutrition Research Laboratory, Department of Medicine, University of Oregon Medical School, Portland, Ore.

IN the preparation of this review reference has been made to 78 published studies on the selenium problem and its various aspects. These articles embrace only those written in the last 5 years. It is the desire of the writer to call special attention to the splendid contributions to this subject by Stenn, Moxon, Dudley, Franke, and Byers and his associates.

The earliest description of what was probably selenium poisoning is found in Marco Polo's accounts of his travels in the 13th century. In this country the Sioux Indians told the white man of a legend based on its effects. Probably the first recorded account of toxic forage was made in 1856 by Dr. T. C. Madison, an army surgeon stationed at Fort Randall, Territory of Nebraska, now more specifically located on the Missouri River in South Dakota. Since then Mayo, Peters, and Lipp, and others have further implicated Wyoming, Nebraska, and South Dakota. These early observations showed that horses, cattle, pigs, chickens, and mules were the principal animals affected. No mention is made of any human involvement. In 1937, Byers described an interesting

situation that he found in Mexico. In a certain valley of that country there has existed for more than two hundred years an obscure disease known as "soliman" whose symptoms bore an exact resemblance to those of "alkali disease."

Although these isolated observations were a matter of record, and stock poisoning continued to be a malady reaching serious proportions, very little if any light was thrown upon the problem until 1934. In this year, Franke reported experiments indicating that the cause of the trouble was resident in the ration. He showed that grain grown in areas where it was known that animals became toxic caused definite symptoms of poisoning when fed to rats. From this time on the solution to the mystery unraveled itself rapidly. Robinson discovered selenium to be present in the toxic grain. Byers showed the wide, though spotty presence of selenium in shale soils. Hurd-Karrer demonstrated the fact that plants could take up selenium from the soil. Finally, Franke proved the implication of selenium by demonstrating that selenium salts when fed to rats produce the same results as when toxic grains were added to the ration. It is true, that Byers showed chromium, vanadium, arsenic, molybdenum and tellurium to be present in the soils along with selenium and

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

that some of these metals were also found in plants. Nevertheless, the work of Franke and others points conclusively to selenium as the toxic factor producing the symptoms of the condition known commonly as "alkali disease" or "blind staggers."

What is now known as selenium poisoning was called "alkali poisoning" in the earlier days. This appellation is now known to be a misnomer for the disease is neither directly nor indirectly caused by alkali water or by alkali spots in the soil. There are two forms of selenium poisoning among livestock. One is an acute form "blind staggers" which is the predominant type in South Dakota, and the other is a semi-acute or chronic form "alkali disease" which is the predominant type in Wyoming.

There is a very definite similarity between selenium, sulphur, and tellurium. They have chemical and physical properties in common. Nutritionally, selenium is regarded as of no importance, but the similarity of selenium and sulphur and the value of the latter in the oxidation-reduction mechanism make it seem possible that in sub-lethal doses, selenium might play a nutritive rôle. Selenium was the only one of the elements used that caused liver pathology in rats. In toxic cereals it is present for the most part, if not exclusively, in organic combination and is probably not in a high state of oxidation. It is bound in the protein molecule in such a manner that it will go into solution only after the protein has been hydrolyzed. Available evidence favors the belief that selenium may be able to displace sulphur in the cystine and methionine molecules. Jones has shown that selenium is associated with cystine and the selenium analog of cystine has been prepared by a couple of workers. For nearly every organic sulphur compound, a selenium homologue has been prepared. These sele-

nium compounds resemble those of sulphur in both their preparation and their reaction.

The amount of selenium in wheat is not proportional to the amount in the soil which may indicate that there is a difference in the forms in which it occurs, and in their availability. The toxicological features of organic selenium compounds may be entirely different from those of the inorganic compounds. In the body, selenium undergoes some type of change for it occurs as an organic protein-like complex in the red corpuscles and as an ether soluble volatile fraction in the urine.

Plants differ greatly in their ability to take up selenium from the soil, and consequently it is present in plants in concentrations which range from traces up to quantities that are lethal to animals. It is the only mineral known to be absorbed from the soil by food plants in sufficient quantities to render them lethal to animals. It may be absorbed in larger quantities in dry than in wet seasons.

There are certain native plants that always contain selenium when they are grown on seleniferous soils. In fact, it appears that some plants called "indicator plants" are incapable of growing on a soil unless it contains this element which may indicate that it is essential for their growth. In one variety of plant, at least, it was shown that the growth rate could be accelerated by the addition of selenium to the soil. These plants are capable of taking selenium out of soil to a much better degree than other plants, and by their death and disintegration steadily enrich the soil in an available form of this element. Other forms of vegetation will therefore show a marked variation in selenium content depending upon the proximity to or absence of these plants. For this reason "indicator plants" are also called "converter plants."

The absorptive power of plant life for selenium depends upon the degree of rainfall, leaching, weathering, the composition of the soil, the geological outcrop upon which the plant material grows, the species of plant, the presence of converter plants, available sulphur, the stage of growth of the plant, and the part of the plant examined. So far as is known at present, no crops grown on a large scale have any special absorptive power for selenium, but all the plants so far investigated absorb some.

Toxicity of cereal grains may vary with the season, with the maturity, and with the length of the storage period. It is thought that the toxicity of selenium depends largely on the ionic combination in which it occurs. All experimental evidence is against the assumption that a tolerance for selenium can be acquired. It favors rather the belief that selenium shows cumulative effects. While the lethal dose of selenium in vegetation is approximately 2 milligrams per animal pound, no minimal concentration at which selenium may be harmful has yet been found. Amounts of selenium less than lethal, have a definite inhibitory effect on the growth of young animals.

Selenium is widespread in the earth's crust, occurring in small quantities (0.005 per cent) in the combined and in the free state. All soils of pyritiferous origin and not exposed to the leaching effect of rainfall, should show the presence of selenium. Primarily, selenium is volcanic in origin. It has been found associated with sulphur in the volcanic emanations. Rain washes the selenium from the air and deposits it in the soil. There the percolating waters gradually leach out the selenium and carry it down to the sea where shales of the upper cretaceous period were formed. The distribution of dust and gaseous material of volcanic origin is world-wide. In the North Central Plains, selenium was deposited con-

temporaneously with periods of high volcanic activity of the Rocky Mountains. It may therefore be said that no soils and especially no ferruginous soils exist in which selenium cannot be found. Soils of arid and semi-arid regions that have in the past been exposed to volcanic action and which have not been exposed to the leaching effect of water may be expected to contain selenium. Many of the toxic districts existing in the Rocky Mountain area have been brought about by vegetable enrichment of selenium through countless cycles of growth and decay of the indicator or converter plants already described.

Selenium has been found not only in the soil and in the crops, but also in the water of temporary springs and in the drainage from irrigated lands. Usually, however, the water supplies of seleniferous areas are either free or so low in selenium as to preclude any possibility that they might be responsible for serious injury unless this water be used for irrigation purposes.

The distribution of seleniferous areas is so widespread (12 states are definitely known to possess such areas and 2 others are suspected), and the economic and public health aspects of the situation so critical that much effort has been and is being spent in determining the best manner to meet the difficulties presented. Some effort has been made to mitigate the toxic effect of grain by storing it for several years before using it. Hurd-Karrer showed that the addition of sulphur to selenium-containing soils reduced the absorption and assimilation of selenium by plants. This has not been borne out in practical trials. Even if it were proved correct, economic considerations would bar its use because the cost of the sulphur would exceed the cost of the land.

The same would be true probably for the use of iron. It has been shown that basic iron reacts with selenite to

produce an insoluble compound. Highly ferruginous soils convert absorbed selenium to a highly insoluble form—a basic ferric selenide.

Moxon has recently made some most interesting observations. When arsenic is fed along with seleniferous grains to rats, the characteristic symptoms of poisoning do not occur. As little as 5 p.p.m. of arsenic in drinking water protects the liver from injury. The animals also remain free from the other symptoms characteristic of this intoxication. Compounds other than arsenic that are non-toxic in themselves have also given promising results.

Physiologically selenium salts may be reduced in the body to the metallic state, as for example by glucose. If this occurs in the intestinal tract, the insoluble material may then be eliminated with the feces. The absorbed selenium undergoes changes whereby some is excreted by the lungs in a volatile form—methyl selenide—and another portion in the urine as an ether soluble volatile compound. It has been noted that animals are capable of detecting minute traces of selenium in forage plants or rations and will avoid them whenever possible. As the result of such observations, it has been suggested that seleniferous areas be allowed to revert to prairie and be used only for grazing purposes.

The federal government is aiding in the solution of the problem by cutting out of agricultural use large areas of seleniferous land. Already about 100,000 acres have been removed from use by outright purchase under the marginal land purchase program.

The participation of the government in the solution of the selenium problem is evidence of its seriousness. Because of the tremendous economic aspects of the problem, the toxicological phases of the research were directed exclusively to the study of animal involvement. Not until the last two years has there been

a great enough realization of the economic and sociologic phases of human involvement to divert some of this research into this aspect of the problem. Since 1936, Dudley has published a few reports on selenium as an industrial hazard, and Smith and his associates have published two reports of surveys made of the inhabitants of involved areas. In contrast to these meager reports are dozens of publications dealing with selenium poisoning in stock, farm animals, and poultry.

In many respects the very nature of the problem is such that animal experimentation must precede studies of human involvement. Experiments on the toxic effect of selenium have been carried out with rabbits, rats, cats, dogs, hogs, calves, fish, and sheep. The pathology and symptoms of selenium poisoning to be described will be, therefore, largely those determined by animal experimentation. The results will be presented concisely and as far as possible correlated with the findings obtained from human studies.

It must be recalled that selenium occurs in vegetation in variable quantities. It is therefore possible that animals feeding over various areas or animals fed rations obtained from different districts may manifest degrees of selenium poisoning ranging from mild to very severe. With a highly toxic ration a sound animal will in a few hours or several days at the most, refuse to eat, become blind, drool profusely, and begin to wander about aimlessly. With a less toxic ration there will be noted a decreased rate of growth, a restricted food intake, an impairment in the general appearance, marked anemia, and, upon necropsy, gross evidences of abnormality.

Little is known of the relative susceptibility of farm animals to the poisonous effect of selenium. It is stated that the untrained individual does not easily recognize selenium

poisoning until the case is well developed. By that time the tissues have been permanently injured. The symptoms and pathology of selenium poisoning have been described under two heads: acute and chronic.

Animals suffering an acute poisoning have a marked pulmonary congestion or edema, hemorrhage and edema, general muscular weakness, labored respiration, and asphyxial convulsions. Animals dying early show little pathological change except for varying degrees of congestion, hemorrhage, and edema of the lungs. The large collections of fluid in the pleural and peritoneal cavities cause an anhydremia which in turn explains the high hemoglobin values found in cases of acute poisoning.

In human beings selenium is partly eliminated by the breath in the form of methyl selenide, a volatile compound which gives rise to the odor of garlic. This method of excretion as well as inhalation possibly accounts for the painful and prolonged bronchitis and pharyngitis found in humans exposed to selenium in the air. There is also an excessive secretion accompanying these disturbances.

Catfish living in water to which selenium has been added become very anemic. On severely toxic diets, rats also develop a progressive anemia frequently showing, in the severe cases, red cell counts as low as 450,000. The hemoglobin usually shows lower values than the red cell count. Often there is a marked reticulocytosis, reaching as high as 8 per cent. The anemia, when well developed, is essentially hypocytic and hypochromic. Anemia, however, has not been described as a symptom of selenium poisoning in humans.

When inorganic selenium or seleniferous grain is added to a ration, food consumption decreases as the quantity of poison increases. Rats voluntarily reduced their food intake to as little as 25 per cent of the normal. There fol-

lowed a corresponding decrease in the rate of growth in the young or a loss of weight in the older animals. Many animals literally starved themselves to death rather than eat the food. The rats would assume a hunched position, their fur would become rough and stained a brilliant yellow around the genitals due to the excessive amount of bile pigment in the urine. Young rats are more susceptible than old ones. Animals on toxic diets do not reproduce well. If both mates were fed toxic food, the matings were infertile. If one animal was fed toxic food and the other a normal diet, occasional fertility resulted. Affected females could not raise young. Rats receiving as much as 17.5 p.p.m. of selenium in their food had no change in the basal metabolic rate.

Chicks hatched from eggs into which selenium salts have been injected were greatly deformed. Similar deformities occurred in eggs laid by hens fed toxic grain. Hens fed diets varying in the amount of selenium showed an equal variability in selenium in their tissues. When chickens were raised on a ration containing 65 per cent toxic grain, there was noted an inhibition in the rate of growth and a decrease and delay in egg production. Egg weights were less. After 6 days of feeding deformed embryos occurred. A continuation of the feeding for 6 more days resulted in complete loss of hatchability.

In acute poisoning in the hog, calf, and sheep, selenium was found in the blood, bile, and urine. The liver, kidneys and spleen contained the largest amount while less was found in the heart, brain, muscles, and lungs.

Acute effects of the ingestion of soluble selenium compounds may be summarized as consisting primarily of early cellular destruction of the liver with later pathological changes throughout the organism. The ingestion of small amounts of selenium compounds

over a long period results in retrograde changes in the liver and kidneys accompanied by a general debility.

After chronic selenium poisoning in rats, the liver, spleen, kidney, and pancreas contained the greatest concentration. In both rats and rabbits, the continued administration of selenium produced cumulative effects. Much of the selenium appeared susceptible to detoxication. Excretion of selenium is rapid at first, but traces remain for a long time. Animals dying after a prolonged exposure to selenium showed not only pathological liver changes, but serous effusions as well. It was noted that pathological changes occurring as a result of as little as 10 days' feeding were never repaired. Rats' stomachs showed a diffuse atrophy of the mucosa with areas of necrosis and ulceration. The liver changes were those of a periportal cirrhosis. The heart muscle and renal tubules were degenerated.

In a study of chronic selenium poisoning in the hog and horse, a distribution of selenium in the tissues similar to that in acute poisoning was observed. High concentrations of selenium were found in the hoofs. It is believed that selenium replaces sulphur in certain amino acids which are utilized in hoof formation. It was observed that cattle poisoned on the range improved when removed to better forage but never recovered from the injury done the liver and kidneys.

Hemorrhages occurred in the subcutaneous tissue and the muscle fascia near the joints. In the joints themselves—especially those involving the long bones—there was marked erosion of the articular surfaces. In horses, cattle, and swine there was a loss of hair from the mane, tail, switch, and body.

How near may the pathological changes and the symptoms of selenium poisoning as observed in animals par-

allel those occurring in man? It is stated that normal urine does not contain selenium and that if urinary selenium is found, it indicates exposure and absorption. In one of the surveys to which reference has already been made, 111 families living in a seleniferous area were examined. Ninety-two per cent of them showed the presence of selenium in the urine. The quantity ranged from 2 to 133 micrograms per 100 cc. Forty-seven and two-tenths per cent of these urines contained over 20 mg. per cent of selenium. The urine from horses showing definite evidences of selenium poisoning contained from 33 to 170 mg. per cent. Many of these individuals showed symptoms of chronic selenium poisoning. In humans as in animals it was found that the younger the individual the greater the effect of selenium.

In selenium poisoning of industrial origin, the symptoms were pallor, gastrointestinal disturbances, a garlicky odor of the breath and perspiration, irritation of the nose and throat, a coated tongue, a metallic taste in the mouth, and nervousness. In the surveys of human beings living in seleniferous regions, there were described vague symptoms of anorexia, indigestion, a general pallor, and malnutrition. From the amount of selenium in the urines of these individuals, it is probable that they were absorbing this element in quantities ranging from 0.01 to 0.2 mg. per kg. per day. All of these individuals had lived on seleniferous farms over 3 years, and most of them from 10 to 40 years.

A more detailed recital of the disorders found among people studied in these surveys includes (a) gastrointestinal disorders, (b) icteroid discoloration of the skin with a history of recurrent jaundice, (c) a sallow, pallid color, (d) rheumatoid and deforming types of arthritis, (e) cardio-renal disease and edema, and (f) changes of the skin

including dermatitis, pigmentation, diseased nails, and bad teeth.

So far human selenium poisoning has not been reported in the toxic areas but because of its occurrence among animals, definite absorption by humans of quantities known to be toxic to animals and the fair degree of resemblance in the symptoms between humans and animals, there is no reason to believe that it does not occur.

Workers in this field have been very cautious in their utterances. One has stated that although there was no definite correlation of symptoms and their incidence with the urinary selenium concentration, the assumption that selenium is harmless is not warranted. He feels that some of the signs of ill health are the direct result of a more or less continuous ingestion of small amounts of selenium over a long period of time. He adds further that symptoms existing in people with low selenium values can be explained as being due to chronic irreparable damage caused at some time in the past.

Intimately connected with the general problem of selenium poisoning as a health hazard to man are the following: (1) the precise sources of selenium to which man is exposed; (2) chemical nature of selenium; (3) the probable amounts absorbed by man in the places where exposure is known to occur; (4) the limits of tolerance, that is, how much may be absorbed with impunity. The selenium to which man is exposed—at least from food sources—is probably for the most part organic in nature. It does not seem probable that as little as 5 mg. of selenium daily could be absorbed more or less continually with impunity.

Man is exposed to the absorption of selenium from two sources—occupational and nutritional. Industries where selenium is a hazard can be divided into primary and secondary classes. The primary group includes industries

which extract, mine, treat, or process naturally occurring minerals which contain selenium in appreciable quantities. The secondary group includes those industries which use selenium or selenium compounds as basic materials for manufacturing processes. The production of dusts, fumes, vapors, or liquors presents opportunities for the introduction of selenium into the body by absorption through the skin, inhalation, and ingestion. That these are definite industrial hazards is attested by the fact that selenium has been found in the urine of workers so exposed.

Mention should also be made of the use of Selocide—a selenium compound used as an insecticide for the control of the Pacific mite and the citrus red spider. Soils catching the run-off spray were also found to contain selenium.

Byers has set the tolerance limit of selenium in foods at 4 p.p.m. It is stated that the form of selenium occurring in cereals is more toxic than the inorganic form. Nearly all the selenium in wheat is concentrated in the gluten fraction. Two samples of gluten contained 0.8 and 15 p.p.m. Since the gluten of wheat carries most of the selenium, the examination of gluten proposed for special diets becomes of extreme importance.

Wheat, corn, barley, and emmer from seleniferous areas have been found to contain selenium. The degree of toxicity is in the order named. Hens fed a toxic grain in their ration, laid eggs that contained selenium. This was equally divided between the white and the yolk. Their own flesh contained selenium in rather high proportions. The selenium content of the eggs and flesh increased as this element increased in the ration.

In several areas in the United States, it has been shown that irrigation tends to diminish the effect of selenium on plants but this was not so when the

irrigation water contained selenium. Irrigation cannot be considered a remedial measure if the water contains selenium. This fact is well illustrated by the findings of Byers in his study of conditions in a certain valley in Mexico. The river water used for irrigation purposes was found to contain selenium. As a result, all vegetables, milk and meat raised in that valley contained selenium. Of special interest in this connection is the finding that Colorado River water at Topock, Ariz., after it has drained seleniferous areas contains 3 parts per billion of selenium. At Yuma it had increased to 4 parts. Similar findings should be expected in other rivers draining seleniferous areas. Now that the water from the Colorado River is to be used for irrigation purposes, the selenium that was carried into the Gulf of Mexico will be deposited in the soils irrigated and thus actually build up new seleniferous areas.

Smith and his coworkers found that foods raised in seleniferous areas gave high selenium values as Table I shows. The values are given in micrograms per 100 cc., or grams of material.

TABLE I

Micrograms per 100 cc.

Beets	0- 118
Beans	38- 204
Bread	25- 100
Barley	165- 575
Cucumbers	0- 55
Carrots	43- 130
Corn	100-1,490
Cabbage	23- 452
Eggs	25- 914
Meats	117- 800
Milk	16- 127
Onions	36-1,780
Oats	200-1,000
Potatoes	24- 94
Peas	38- 204
Rye	87- 380
Rutabagas	172- 600
Tomatoes	0- 122
Wheat	115-1,880
Water	0- 33

Lettuce and turnip greens have been reported to contain selenium in amounts

ranging from 0.3 to 150 p.p.m. Of the food listed, cereals are of special importance because of the quantities raised and their wide distribution to the markets of the world. Next in importance are the food concentrates such as egg powder, milk powder, cheese, gluten, and the flesh of chickens, cattle, hogs, and other flesh-producing animals. Fruits become involved because of the use of sprays. Vegetables and fruits both may become involved in newly developed irrigation districts. In this country milk from "alkalied" cows contained enough selenium to produce in their nursing young all of the prominent symptoms of selenium poisoning. Suckling pigs also became "alkalied" and lost their hair because of the transmission of selenium through the milk. The placenta is capable of transmitting selenium to the fetus so that the young are born with selenium in their tissues. This increases during the nursing period.

The future of seleniferous lands is a problem. The ability of animals to detect toxic vegetation would seem to indicate that one solution at least would be to let affected areas revert to natural prairie land to be used only for open grazing.

The human aspect of selenium poisoning is less well known. Only two efforts have been made thus far in determining to what extent humans may be involved. The awakening consciousness that the human being as well as the farm animal has an economic value; that human problems as well as agricultural ones demand concerted action, is making it highly desirable, if not imperative, that research laboratories and public health agencies make every effort to bring about a clearer understanding of the questions involved.

Only a few cases of injury to man have been definitely determined. The only studies made on humans have shown the presence in the urine of

selenium in quantities equal to that found in the urine of toxic animals. To deny the existence of selenium poisoning as such in these individuals because studies have not shown a symptom pathognomonic of selenium poisoning is assuming a very conservative attitude. Byers, in his Mexican studies, was not willing to commit himself by stating that the evident ill-health of the inhabitants was due to the selenium content of their food and concluded that the question was problematical and worthy of study.

By the investigators who have studied the selenium problem the most thoroughly, the public health aspect of the situation is limited exclusively to the affected areas. It should not be overlooked, however, that the largest part of the world's wheat is grown in semi-arid soils where selenium, if present, would tend to remain and perhaps even accumulate in the soil. Of equal importance is the contamination of food material by seleniferous sprays. Byers and Knight state that while it is true quantities of toxic foodstuffs have been produced and marketed, and that unless preventive measures are taken they will continue to be produced and marketed, no serious concern need be felt except in the areas concerned. In this connection it should not be forgotten that toxic areas in this country have been found in some 14 states and that the investigation of other areas is not yet complete.

Others tend to minimize the public health aspects of the problem by stating that in the general market it is impossible that any serious concentration of toxic food is likely to reach any individual. It is freely admitted, however, that "there exists the possibility that the health of the public as well as that of livestock might be involved since selenium bearing foods grown upon seleniferous soils also enters human dietary."

There is no doubt that the selenium problem is one of such magnitude that it cannot be ignored. It presents to research people and public health authorities a great responsibility. Not only should food supplies derived directly or indirectly from seleniferous areas be scrutinized, but special emphasis should be placed upon the protein concentrates or derivatives of those foods. Foods that have been sprayed with selenium-containing sprays should also be given consideration and soils catching the spray run off should be studied from the standpoint of the building up of seleniferous soils. Foods raised on soils exposed to the wash-off from certain mines and on soils in proximity to smelters should also be regarded in the same light. A new and equally important aspect of the problem is the strong likelihood of increasing seleniferous areas in irrigation districts using water containing selenium. This problem is of more than theoretical interest in the lower Colorado River since Byers demonstrated the presence of selenium in appreciable quantities. This same authority is responsible for the statement that "irrigation does not diminish the effect of selenium in plants when the water contains selenium." Furthermore, the use of such water for irrigation purposes in arid regions where the rate of evaporation is high may actually build up new seleniferous areas. Those considerations mentioned by Marcovitch in connection with fluorine should be considered here also. Food raised in these districts should also be studied from the standpoint of an increasing content of selenium. Last but not least is the consideration that should be given the worker in those industries where selenium is either used or is present as a by-product.

No more fitting conclusion can be given to this review than the following statement made by Smith, Franke, and Westfall:

More detailed information regarding the sources of selenium; accurate knowledge concerning the quantitative relationship between the selenium excreted to that ingested and stored in the tissues; more intimate knowledge concerning the chemical nature of the compound or compounds of selenium occurring in foodstuffs, and a thorough knowledge of the fate of these compounds in the body, are some phases of the general problem requiring solution before its public health significance can be fully appreciated.

To this must be added, of course, the dangers that may accrue in developing new seleniferous areas through spray processes, irrigation, and industrial practices and the marketing of foods raised in such areas; foods subjected to seleniferous sprays and the various concentrates made from these foods.

Mass Immunization Against Diphtheria with Sordelli's Toxoid and Contact Immunization*

ALBERTO P. LEÓN, M.D., M.P.H., R. HERNÁNDEZ
VALLADOS, AND F. ESCARZA

*Chief; and Epidemiologists, Division of Epidemiology, Department
of Public Health, Mexico, D. F., Mex.*

IN Mexico diphtheria has been more frequent than was believed to be the case in other countries. An average of 1,295 deaths occurred annually from 1931 to 1936. The trend of mortality from this disease has been increasing from 1930 to 1936, as can be seen by the following death rates: 1930-5.4; 1931-6.5; 1932-7.8; 1933-7.4; 1934-7.5; 1935-7.0; 1936-7.6.¹

Probably this is not an apparent increase but a real one, because the trend of most of the other communicable diseases is downward and for this reason it would not be wise to think that in the case of diphtheria the increase is due to better registration. Besides this, the increasing crowding of our rural population into the cities, due to social, political, and economic reasons, and the high percentage of susceptibles to diphtheria in our population, as we shall see later, are two factors that may explain the increase of morbidity and mortality from this disease.

For these two reasons diphtheria is a very important health problem in Mexico. Each year more attention is

given to its control, and research work is now being done to improve methods and technics of control.

Diphtheria has been very prevalent in the past in most countries, and if it is now under control in many places, it is due to the constant and careful preventive measures taken, but as soon as these are relaxed the disease spreads. In some countries the mortality is rising, notably in Germany from 1931 to 1935; in England from 1932 to 1937; Poland from 1929 to 1934.² In some others, like Japan, it is stationary; in the United States and Canada, there have been some outbreaks that caused a number of cases and deaths. For all these reasons diphtheria is a disease that deserves careful and permanent attention from the public health authorities.

The main factor in the control of diphtheria has been active mass immunization and immunization of the contacts of cases. Several products have been used in active immunization, but the one most commonly employed has been Ramon's anatoxin, introduced in 1924.³ This has the disadvantage that several injections are needed and in mass immunization this is a great obstacle to reach the proportion of im-

* Read at a Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

munes necessary to protect the herd, since, for several reasons, many do not receive the second or the third doses. Ramon's anatoxin has also the disadvantage that it takes several weeks to induce immunity, and consequently it cannot be used to protect contacts of cases of diphtheria that have been already infected or may be infected within a few days or weeks. For this purpose antitoxin has been used; but the immunity that antitoxin confers lasts only 2 or 3 weeks, and after that the contacts may be still in danger of infection. It is not advisable to repeat the injections of antitoxin for reasons that are well known. What is done at present is to induce active immunity to diphtheria contacts 2 or 3 weeks after the injection of antitoxin. This procedure is not practical because it is necessary to follow up the contacts and to inject them several times.

To avoid the disadvantages found in mass immunization against diphtheria with Ramon's anatoxin and other products which are given in repeated injections, several investigators have tried to induce immunity with a single dose of concentrated and activated toxoids. The alum precipitated and the aluminium hydroxide activated toxoids are the most commonly used. Glenny, Pope, Waddington, and Wallace⁴ proved that the precipitate made by alum in the diphtheria crude toxoid was more antigenic than the latter for the immunization of horses, and this was confirmed in human immunization by Park, by Wells, Graham and Havens. Now the use of this produce is very widespread in the United States, England, Scotland, and other countries. Cumming reported to the Office International d'Hygiene Publique that 85 per cent of the diphtheria immunizations in the United States are made with alum precipitated toxoid.²

Lindes Krom, Lang and Schmith,⁵

and Schmith and Hansen,⁶ activated the acid precipitated toxoid adding aluminium hydroxide ($Al(OH)_3$). This product has been extensively used in Denmark and Argentine. Sordelli modified the original technic for the preparation of the alumina activated toxoid and has reported great success with it for mass immunization.

For the immunization of contacts it would be very important to have a method by which it was possible to induce a rapid and lasting immunity, so that those exposed to infection could be protected immediately, and for a long time. This could be done if it were possible to induce simultaneously the passive and active immunity. This is not possible with antitoxin and Ramon's anatoxin because, as several authors have stated, particularly Rose-nau,⁷ if these two products are injected at the same time or a few hours or days apart, they combine and interfere with one another, nullifying their immunizing properties.

Schmidt and Kjaer, quoted by Leonard and Holm,⁸ observed that toxoid precipitated with acetic and hydrochloric acids do not flocculate with antitoxin; in other words, they have lost their property to combine with antitoxin. Schmith and Hensen, quoted by the same authors,⁸ state that "diluted diphtheria toxine treated with aluminium hydroxide are not stable in their flocculating properties in contact with antitoxin," and conclude from their investigations with alumina activated toxoid that it remains antigenic, notwithstanding that it has lost its combining property.

We observed that Sordelli's toxoid has lost its property of combining with antitoxin, and this gave us the idea that it might be possible to induce simultaneous immunity, active and passive, with Sordelli's toxoid and antitoxin.

This paper is intended to report on the investigations performed in Mexico

by us on mass immunization against diphtheria with Sordelli's toxoid and the simultaneous immunization, active and passive, of the contacts, with Sordelli's toxoid and antitoxin.

We divide the account of our investigation into two parts: the first dealing with mass immunization, and the second with the immunization of contacts.

MASS IMMUNIZATION

We Schick tested 4,309 persons of all ages. Readings were made from the first to the fourth day. We classified as susceptibles all who gave a positive or combined reaction, and as immunes those who gave a negative or pseudo-positive reaction. Three thousand, one hundred and ninety-two, or 74.1 per cent, were susceptibles, the percentage of susceptibles being higher at the lower ages, though 48.8 per cent of those 25 years of age or over were found susceptible. The percentage of adult susceptibles found in Mexico is higher than that found in other countries. The susceptibility to diphtheria of different age groups, as shown by the Schick test, is presented in Table I.

The immunes were not further taken into consideration. The 3,192 susceptibles were divided into 3 age groups.

Group 1 comprises from 0 to 5 years age; group 2, from 6 to 10, and group 3, from 11 years on. Each group was subdivided into 3 subgroups. Those of subgroup I were injected with $\frac{1}{2}$ cc. of Sordelli's toxoid; those of subgroup II with 1 cc., and those of subgroup III with $1\frac{1}{2}$ cc.

The toxoid used was prepared in the Instituto de Higiene of Mexico according to the technic of Schmith modified by Sordelli, briefly described as follows:

From diphtheria toxin of 80 m.l.d. potency was prepared the anatoxin adding 0.4 per cent formalin and storing in the incubator until detoxification. One cc. of the anatoxin protected guinea pigs of 250 to 300 gm. weight against 5 m.l.d. To the anatoxin was added a 20 per cent sulfuric acid solution until a pH of 3.2 to 3.4 was reached. It was left to settle for 20 minutes and then centrifuged 1 hour at 3,500 r.p.m. The supernatant was discarded and the sediment redissolved in distilled water. To this solution was added NaOH until a pH of 7.6 to 7.8 was reached, and then enough distilled water was added to bring it up to $\frac{1}{10}$ the original volume. Sterilization was done by filtration through Berkefeld candle and finally aluminium hydroxide (Al

(OH)₃) was added in the proportion of 4 mg. per cc.

The Sordelli's toxoid was prepared by G. Varela and Aguirre Colorado.

The lots of toxoid we used had from 10 to 15 L_t units per cc. Tests were always made for potency, sterility, and innocuity according to Government Standards.

Of the 3,192 susceptibles injected with toxoid, 1,802 were retested at intervals of 20 to 307 days, and 1,357, or 75.3 per cent, gave a negative reaction or, in other words, became successfully immunized; but it seems that the percentage of immunizations varied with the age of the persons injected, the dose employed and the time interval between injection and test, although

the differences observed are not statistically significant.

The percentage of persons successfully immunized was greater among the higher ages, with the larger doses, and when the interval between injection and test was longer. The first statement is based on the figures in column 8 of Table II, and these figures were chosen because they have the lower probable errors. The second statement is based on the figures in the last line of Tables II and III; and the third on figures in column 8 and 2d, 3d and 4th lines of Table III.

On the average, a little more than 80 per cent of susceptibles injected with $1\frac{1}{2}$ cc. (15 to 22.5 L_t) of Sordelli's toxoid became immune as shown by

20 to 307	151	93	61.59	5.01	894	653	73.04	2.44	757	611	80.71	2.93

the Schick test, 73 per cent of the injected with 1 cc. (10 to 15 L_r) and 61 per cent of those injected with $\frac{1}{2}$ cc. (5 to 7.5 L_r). These percentages are reached 20 days after the injection and are also found after 307 days.

The reactions observed in persons injected with Sordelli's toxoid were divided in local and general, and the locals in mild, moderate and strong.

We considered as strong local reactions those in which inflammatory signs were present at the site of the injections in an area of about 5 cm. in its longer diameter; moderate, when the area of inflammation was less than 5 and more than 2 cm. in diameter, and pain moderate; and mild reaction, when the area of inflammation was limited to less than 2 cm. in diameter and pain absent.

An average of 50 per cent had a local reaction, and 13 per cent a general reaction. Both reactions were a little more frequent with the larger doses, but no significant difference was observed with the age.

The local reactions were mild in 30.3 per cent, moderate in 48.2 and strong in 19.3.

The general reactions were always mild, consisting of a moderate rise of the temperature for a few hours, with the exception of one case in which an urticarial exanthem was observed.

We also observed the formation of abscesses at the site of the injection in 8 cases among the 3,192 persons injected with Sordelli's toxoid; but the evidence pointed to careless technic in making the injection as the cause. *Staphylococcus pyogenes* was found in the pus obtained by aseptic puncture of 4 abscesses.

THE IMMUNIZATION OF CONTACTS

As said, I conceived the idea that it could be possible to induce simultaneously passive and active immunity against diphtheria, with antitoxin and Sordelli's toxoid, because I observed that

this toxoid had lost its property to combine with antitoxin. To prove this idea we performed laboratory investigations. Two lots of several guinea pigs each were injected with appropriate doses of diphtheria antitoxin and Sordelli's toxoid, at the same time but at different sites. To test the production of passive immunity, the guinea pigs of the first lot were injected with 5 m.l.d. of diphtheria toxin 24 hours after the injection of antitoxin and toxoid. Two normal guinea pigs were also injected with diphtheria toxin as controls.

Within 3 days after the injection of the toxin, the controls died, but the guinea pigs injected previously with antitoxin and toxoid survived and did not show signs of illness during the following month.

In order to test the active immunity induced by the simultaneous injection of toxoid and antitoxin, the second lot of guinea pigs were injected with 5 m.l.d. of diphtheria toxin 30 days after the injection of antitoxin and toxoid. Two normal guinea pigs were also injected with toxin, as controls. Within 24 hours after the injection of the toxin, the controls died, but the guinea pigs that had been previously injected with toxoid and antitoxin survived and did not show signs of illness. The protocols of these experiments have been published elsewhere.⁹

From the experiment described we drew the 2 following conclusions:

1. The Sordelli's toxoid and the diphtheria antitoxin confer simultaneous immunity, active and passive, when they are injected at the same time, but at different sites in doses at which the serum confers passive and the toxoid active immunity when injected separately.

2. When Sordelli's toxoid and diphtheria antitoxin are injected at the same time but at different sites, they do not combine *in vivo* and do not interfere with one another.

Based on these 2 conclusions we made investigations in the field and in human beings.

TABLE IV

Schick Reactions Resulting After Simultaneous Injection of Diphtheria Antitoxin and Sordelli's Toxoid in 90 Susceptible Individuals

Ages	Total of Indi- viduals Studied	First Schick 1 to 3 Days After Injection				Second Schick			
		Positive		Negative		1 Month After		2 Months After	
		No.	%	No.	%	Pos. No.	Neg. No.	Pos. No.	Neg. No.
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
0 to 4 years	29	29	100.0	2	8	4	8
5 to 9 "	26	26	100.0	2	10	4	9
10 to 14 "	12	12	100.0	..	7	..	4
15 to 20 "	4	4	100.0	..	1	1	2
20 and over	19	2	10.5	17	89.5	2	10	..	6
Totals	90	2	2.2	88	97.8	6	36	9	29
Total Negative React. 81.2 %									

The investigations were made among contacts of diphtheria cases and carriers. The contacts were Schick tested; those who gave a negative reaction (immunes) were not taken into consideration. The Schick positives (susceptibles) were injected with 1,000 to 1,500 A.U. of diphtheria antitoxin and with 1 cc. to 1½ cc. of Sordelli's toxoid. These products were injected subcutaneously, at different sites, but at the same time.

Within 24 to 72 hours after the injection of toxoid and antitoxin a second Schick test was made to see if passive immunity was established and 1 or 2 months later a third Schick test was made to see if active immunity was induced.

In accordance with the plan outlined 90 susceptible contacts of diphtheria cases or carriers were injected with Sordelli's toxoid and diphtheria antitoxin, and Schick tested before and after the injection: 88, or 97.8 per cent gave a negative Schick test within 24 to 72 hours after they had been injected, and 2, or 2.2 per cent, gave a positive reaction. It must be said that the 2 persons who remained susceptible were adults injected for some reason with

only 900 A.U., a dose which is insufficient, as we know.

Of the 90 susceptible contacts injected with toxoid and antitoxin, and Schick tested before and after the injection, only in 80 was a third Schick test made 1 or 2 months after the injection. Among 42, the Schick test made 1 month after the injection, 36 gave a negative reaction and 6 a positive one. In 38 the test was made 2 months after the injection—29 gave a negative reaction and 9 a positive. Taking into consideration the Schick tests made 1 month and 2 months after the injection of toxoid and antitoxin, the result was negative in 82.2 per cent of the contacts injected (see Table IV).

In 132 persons injected with toxoid and antitoxin it was possible to observe the reactions that followed with injection of these products.

In 96, or 72.7 per cent, a local reaction was observed, of which 18, or 13.5 per cent, were strong; 26, or 19.7 per cent, were moderate; and 52, or 39.4 per cent, were mild. In 34, or 27.5 per cent, a general reaction was observed (see Table V).

The criterion followed to classify the reactions was the same as stated above.

SUMMARY AND CONCLUSIONS

We have described the technics and methods followed in mass immunization against diphtheria with Sordelli's toxoid. The percentage of persons successfully immunized after the injection of $\frac{1}{2}$ cc., 1cc. or $1\frac{1}{2}$ cc. of toxoid has been specified. The correlation of the doses of the product, age of the persons injected, and time between the injection and immunity test, with the percentage of successful immunizations have been studied. The frequency of local or general reactions after the injection of Sordelli's toxoid and their intensity were observed.

We have also described our studies as to the simultaneous immunization, active and passive, of the susceptible contacts of diphtheria cases and carriers, with Sordelli's toxoid and anti-toxin and results obtained.

From these studies we draw the following conclusions:

1. The Sordelli's toxoid, acid precipitated

and aluminium hydroxide activated, when injected in a single dose of $1\frac{1}{2}$ cc., having 10 to 15 L_t units per cc., confers immunity to an average of 80 per cent of the susceptibles of all ages so injected.

2. The immunity induced with Sordelli's toxoid is already acquired 20 days after the injection and remains at the same level at least 307 days later, according with our observations.

3. The higher proportions of successful immunizations with Sordelli's toxoid are observed in the older age groups. Probably this is an indication that the doses must be higher for the preschool age children than for school age children and adults.

4. Local reactions at the site of the injection of toxoid were observed in about 50 per cent of the persons injected, and general reactions in 13 per cent; but both reactions were always mild and transitory. They do not contraindicate the use of Sordelli's toxoid.

5. We believe that Sordelli's toxoid is a product that can be used with advantage in mass immunization against diphtheria since about 15 L_t units in a single injection are enough to immunize 80 per cent of the persons injected; but we think that it would be convenient to prepare and use more potent toxoids, probably with not less than 30 L_t units

per cc., in order to obtain higher proportions of successful immunizations.

6. Simultaneous immunization, active and passive, against diphtheria, can be induced with Sordelli's toxoid and diphtheria antitoxin, if these products are injected subcutaneously, but at different sites, in doses in which the toxoid confers active and the antitoxin passive immunity when used separately.

7. We believe that the simultaneous immunization, active and passive, with Sordelli's toxoid and antitoxin should be the method of election for the immunization of susceptible contacts with diphtheria cases or carriers, since with this method they will be protected immediately and for a long time, or permanently. Probably alum precipitated toxoid may be used as well as Sordelli's toxoid for this purpose.

Administration of Laws for the Prevention and Control of Occupational Diseases*

THEODORE C. WATERS

Mullikin, Stockbridge & Waters, Baltimore, Md.

LEGISLATION providing for the compensation for and prevention of occupational diseases has been the result of a definite economic need in our present-day industrial relations. In the same manner that Workmen's Compensation Acts were necessary to provide some new method to adjust disputes between employer and employee as to the liability of an employer for accidental injuries, so occupational disease compensation acts have become essential to provide the medium for the settlement of claims for occupational disease injuries. Industrialists today accept the obligation imposed upon industry to provide compensation for injuries to their employees arising out of and in the course of employment, no matter whether they are caused by occupational disease or accidental means.

One of the most serious problems that have arisen in connection with the administration of the Workmen's Compensation Acts has been the problem of disease caused or aggravated by accidental injuries. There had already de-

veloped the tendency for these laws to be administered as general health insurance laws, and this tendency became even more acute with the adoption of laws providing compensation for occupational disease injuries. The primary purpose of the compensation statutes is to compensate only those injuries that are characteristic of and peculiar to the employment where the hazard of injury occurs. If there were no such limitation as to the scope of the compensation acts, they would inevitably be administered as general health insurance laws, which was certainly not the intention or purpose sought to be accomplished by their enactment.

The American Public Health Association has had as one of its major interests the subject of industrial hygiene, and your officers, committees, and members are to be commended for the part the Association has played in the protection of the health of workers engaged in trade and exposed to the hazards of industrial disease. You have tendered your assistance to compensation commissions and legislative committees in the draft and preparation of occupational disease laws that were later enacted, and your As-

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

sociation is now concerned with the administration of these laws. Many perplexing problems have already arisen and will continue to arise in the course of this administration, and the continued assistance and interest of your Association is essential in order for this administration to be successful.

In the United States occupational disease compensation laws have been of comparatively recent enactment; the States of California and Wisconsin enacted such laws in 1919; the State of New Jersey in 1924; North Dakota in 1925; Minnesota and Connecticut in 1929; and the remaining 15 states have enacted their laws since 1930.* During this period public hysteria developed about the subject of occupational diseases in industry. I do not mean to be critical of this fact, because it has served to emphasize an industrial problem which should have received legislative attention. However, one of the results of this hysteria has been the hasty enactment of ill-advised laws, whose provisions have led to difficulties of administration and the occasion of unfortunate industrial conditions that might have been avoided by more careful supervision of the legislative programs. The experience in the administration of many of these laws has not extended over a sufficient period of time to appraise properly their merits or demerits. It is to be regretted that this legislation has not been more uniform in certain of its aspects, although future amendments may tend toward uniformity and remove some of the inequities that at present exist. None of the laws so adopted are perfect; many of their provisions are objectionable; and, in

the course of their administration, there have developed and will continue to develop problems that could not have been foreseen at the time of their enactment. In every state questions have arisen, making necessary the judicial construction of these laws in order to determine the liabilities of employers and the benefits granted to claimants thereby.

As typical of the confusion that has arisen with respect to certain of these laws, it is interesting to review certain cases wherein judicial interpretation was essential in order to determine the scope of the laws so enacted.

You are all familiar with the type of occupational disease law that provides what is known as "general coverage" for all occupational disease injuries. These laws do not schedule or classify the diseases that are compensable, but purport to make compensable any and all occupational diseases. As an example, consider the following provisions of the laws of the States of New York, Connecticut, and Illinois.

The New York Workmen's Compensation Act was originally amended to compensate a scheduled list of occupational diseases. By the Acts of 1935, Chapter 254, the following was added to the schedule: "Item 28. Any and all occupational diseases." The law itself does not define the term "occupational disease," and you will readily recognize the need for judicial interpretation of this term in order to determine the scope of the law.

The Connecticut Compensation Act was amended in 1927 to provide compensation for accidental injuries and "occupational disease as herein defined." The Act contains the following definition of occupational disease:

The words "occupational disease" shall mean a disease peculiar to the occupation in which the employee was engaged and due to causes in excess of the ordinary hazards of employment as such.

* Delaware—1937
Illinois—1936
Indiana—1937
Kentucky—1934
Massachusetts—1932
Michigan—1937
Missouri—1931

Nebraska—1935
New York—1930
North Carolina—1935
Ohio—1931
Pennsylvania—1937
Rhode Island—1936
Washington—1937
West Virginia—1935

The occupational disease law adopted by the State of Illinois in 1936 contains the following definition of the term "occupational disease."

The term "occupational disease" means a disease arising out of and in the course of employment. Ordinary diseases of life to which the general public is exposed outside of the employment shall not be compensable, except where the said diseases follow as an incident of an occupational disease as defined in this section.

What is the meaning of the term "occupational disease" as set forth in these statutes and what diseases that arise out of and in the course of employment are thereby made compensable?

It is interesting to note the judicial interpretation of the courts construing the term "occupational disease" and defining the scope of the law granting compensation therefor.

The case of *Goldberg v. 954 Marcy Corporation*, reported 12 N. E. Rep. (2nd) at page 311, involved an appeal from the action of the Appellate Division, sustaining an award granted by the New York Compensation Board to the claimant for an alleged occupational disease injury. The duties of the claimant required her to sell tickets for a motion picture theatre in a small sidewalk booth which was heated by an electric heater. Her claim set forth that her legs became weakened by the heat and that on her way to the doctor's office for medical attention, she fell and sustained a fracture of the ankle. I quote the following averments of her claim:

My condition was caused by the electric heater in the cash box. It drew the blood out of my feet and caused blotches and veins to come out, making my feet weak.

The referee awarded compensation on the theory that the injury sustained was both an accident and an occupational disease. The Workmen's Compensation Board sustained this finding

on appeal, which was likewise affirmed by the Appellate Division. The New York Court of Appeals, in the case cited above, affirmed the award on the ground that the plaintiff had suffered accidental injury arising out of and in the course of her employment and, in the course of its opinion, in refusing to affirm the appeal on the ground that the claimant had suffered an occupational disease, said:

An occupational disease is one which results from the nature of the employment, and by nature is meant, not those conditions brought about by the failure of the employer to furnish a safe place to work, but conditions to which all employees of a class are subject, and which produce the disease as a natural incident of a particular occupation, and attach to that occupation a hazard which distinguishes it from the usual run of occupations and is in excess of the hazard attending employment in general. Thus compensation is restricted to disease resulting from the ordinary and generally recognized risks incident to a particular employment, and usually from working therein over a somewhat extended period. Such disease is not the equivalent of a disease resulting from the general risks and hazards common to every individual regardless of the employment in which he is engaged.

It is a fact that today, in New York State under the present law, there are pending claims for such diseases as asthma, tuberculosis, pneumonia, colds, bronchitis, and other human ills not peculiar to or characteristic of the trade or employment wherein the claimant is engaged. I do not mean to imply that compensation will be awarded for all such cases and express the hope that the New York statute will never be construed to provide general health insurance for employees. However, there is always present the danger of awards for disease injuries that are not truly occupational in their nature.

A case that arose in connection with the construction of the Connecticut statute is that of *Madco v. I. Dibner & Bro., Inc.* (1936), 186 Atl. 616. There the claimant contracted pul-

monary tuberculosis while employed in a dress factory. In denying compensation, the court, referring to the definition quoted above, said:

To award compensation to the claimant in this case would be to go against the legislative intent emphasized in the amendment of 1927 and to violate the statute as it has since stood.

The Illinois statute above cited became effective in 1936, and to date there does not seem to be any reported opinion wherein the meaning of the term "occupational disease" has been judicially construed. However, there are claims now pending under this statute for many of the common ills of life, not peculiar to any particular occupation, such as "pneumonia, flat feet, bronchitis, etc." It is inevitable that cases involving such diseases will be passed upon by the courts to determine whether or not they are compensable under the statute.

Recognizing the difficulties of administration that are caused by the inherent defects in these laws, I would like to discuss certain of their administrative provisions that are of particular interest to your Association. These subjects relate to provisions for the determination of occupational diseases and the extent of disability arising therefrom, together with provisions for control and prevention.

- I. Provisions for the creation of Medical Boards or the appointment of medical examiners, defining their functions.
 1. To advise the administrative agency whether or not the claimant is suffering from the occupational disease for which compensation is claimed.
 2. To determine the degree of disability caused by the occupational disease.
- II. Provisions for the establishment of Bureaus of Industrial Hygiene, defining their functions.
 1. Maintenance of an occupational disease reporting system.
 2. Establishment of rules and regulations for the control and prevention of occupational diseases.

3. Maintenance of a factory inspection service.

PROVISIONS FOR THE CREATION OF MEDICAL BOARDS OR THE APPOINTMENT OF MEDICAL EXAMINERS

The adoption of compensatory legislation makes necessary the delegation to some administrative agency of the power to determine whether or not the claimant is suffering from an occupational disease, and the extent of disability arising therefrom. In many occupational disease claims the medical testimony offered by the claimant and the employer will be controverted and expert medical evidence that is highly technical will be offered on behalf of the contesting litigants with resulting confusion and uncertainty in the minds of the agency charged with the administration of the law. The fees payable to expert witnesses are substantial and the parties litigant may, in given instances, expend exorbitant sums in order to accomplish successful results. The employee, unable to finance such trials, is at a distinct disadvantage and may not have available competent medical advice to present his case properly. Under such circumstances, what is the administrative agency to do? To whom may it turn for unprejudiced nonpartisan advice? What agency can be established as representative of the State, to serve the function of determining these all-important medical questions upon which the award or denial of compensation will depend? An answer to this query has been found in many of the occupational disease compensation acts, wherein provisions have been made for the appointment, either of a medical board, or of special medical examiners.

A medical board, composed of competent, impartial physicians, representing the State, disinterested as a party in the proceeding, benefitting by its continued experience in handling this type of claim, is the best agency to

determine medical questions. In order to accomplish the appointment of a board composed of competent, non-political appointees, it may be well to consider the suggestion that the appointments should be made by the governor of the state from a list of nominees to be submitted by the dean or deans of the medical departments of state universities or other medical schools within a given state. There should be the requirement that appointees should have had extensive practice and experience in the diagnosis, treatment and care of occupational diseases. The board should be empowered to make rules regulating its procedure, to contract for laboratory work, to make necessary investigations of working conditions, to provide for the ordering of autopsies, to examine claimants, and to determine all medical issues presented by the claim. All claims involving occupational diseases should be referred to this board for investigation, hearing, and report, which report, when completed, should be filed in the record of the case. At hearings before the board, either party should be given the privilege of offering testimony of its own doctors or such other witnesses as they may desire, and the further privilege of cross-examination of witnesses offered by the other party.

In those states where the findings of the medical board are final, the board should continue its jurisdiction over the case, with the privilege of reopening it at any time it elected to do so, for the purpose of reviewing, reversing, or modifying its decision in such manner as it deems proper. In those jurisdictions where the board serves solely in the capacity of advising the administrative agency, its members should offer testimony as to their findings before the administrative agency and be subject to examination and cross-examination by the parties litigant.

FUNCTIONS OF MEDICAL BOARDS OR MEDICAL EXAMINERS

1. To advise the administrative agency whether or not the claimant is suffering from the occupational disease for which compensation is claimed—

Upon the filing of a claim for occupational disease compensation, the claimant should be required to submit to such medical examinations as the medical board deems necessary or proper to determine the existence of injury and the extent of disability from which the claimant is suffering. In the event that the claimant refuses to subject himself to such examination, the payment of compensation should be suspended until he does submit. Broad powers should be granted to study the condition of the patient over such period of time and under such conditions as are necessary for the proper determination of injury. Either party litigant should have the privilege of offering to the medical board the testimony of its own medical advisers, so that the right of each party to present its own evidence would be retained. The witnesses so offered should be subject to examination by the other party and by the individual members of the medical board. The medical records, laboratory and X-ray findings of either party should be offered in evidence and made an official part of the record of the proceedings before the medical board.

Provision is made, under many of the occupational disease laws, for the conduct of autopsies in death cases. Such autopsies may be ordered by the medical board for the purpose of determining the cause of death since, in the case of many of the occupational diseases, an autopsy will afford the best evidence as to whether or not death was caused by the occupational disease for which claim is made. The board should have the power to order such autopsy and should supervise its conduct, with

the privilege to its members to attend and participate in the examination of the decedent. The findings should be certified by the board as a part of the record in the case.

2. To determine the degree of disability caused by the occupational disease—

One of the most difficult factual determinations involved in occupational disease compensation is that of the extent of disability arising from certain occupational diseases. The formulae that have been established in the Workmen's Compensation Acts providing compensation for accidental injuries are not and cannot be made applicable to occupational disease claims. In the case of many of the occupational diseases the medical profession has not yet agreed upon a satisfactory method for the determination of partial disability. In any given case each party litigant could offer its own testimony as to the extent of the injury and the degree of disability that would be in hopeless conflict with the testimony offered by its opponent. It is recognized that this problem is one that can only be solved after extensive experience in the administration of occupational disease laws and the adoption of a satisfactory method, accepted by the medical profession, for the determination of the degree of disability.

In view of the perplexity of the question and the desire to provide the most expeditious method for the determination of the extent of injury and the degree of disability, it is suggested that this function should be served by the medical board, which should be better able to decide these questions.

Of the occupational disease laws now effective, the laws of the States of Connecticut, Delaware, Missouri, Nebraska, and New Jersey make no provision for the appointment of medical boards. In the laws of the other states such provisions are made. The laws

of the States of Massachusetts and Michigan make the diagnosis and opinion of the board upon medical questions binding upon the agency administering the law. In the States of California, Illinois, Indiana, Kentucky, Minnesota, New York, North Carolina, North Dakota, Ohio, Pennsylvania, Rhode Island, Washington, West Virginia, and Wisconsin, provisions are made for medical boards and examining physicians to act in an advisory capacity to the agency administering the law. The importance of medical boards cannot be over-emphasized and it is submitted that the successful administration of occupational disease laws will depend upon the proper determination of medical questions of fact that are involved in these claims.

Is it not reasonable to believe that the most satisfactory determination of medical issues presented by claims arising under these laws could be made by a board of examining physicians? If the determination of these questions is left to lawyers, judges, or other bodies of laymen, each given case will require the parties litigant to educate the administrative agency in the intricacies of the industrial disease for which compensation is sought. There is no agency in the United States whose voice should be more effective for the accomplishment of this result than the American Public Health Association, and it is to be hoped that it will be the policy of your Association to extend its support and coöperation to the state medical agencies that are charged with the administration of these laws.

PROVISIONS FOR THE ESTABLISHMENT
OF BUREAUS OF INDUSTRIAL HYGIENE

There is one phase of the subject of the administration of occupational disease legislation that merits your careful consideration. That is the subject of prevention and the legislative provisions designed for the protection of

employees against the hazards of occupational disease. It is to be regretted that legislation heretofore enacted by the several states has placed primary emphasis upon compensation, while the subject of prevention has not received the attention that has been justified. In most of the states having occupational disease laws the only legislative methods provided for the control and prevention of occupational diseases are found in the health and labor laws, which are not primarily adaptable to the peculiar problems presented by occupational disease hazards. However, in several of the states, there is specific provision in the occupational disease law for the establishment of bureaus of industrial hygiene and a method provided for the adoption of rules and regulations designed for the control of occupational disease hazards. Let us refer briefly to legislative provisions of this type.

Article 4a, section 65, subsection 2 of the Workmen's Compensation Law of New York, effective June 6, 1936, provides as follows:

The industrial commissioner and the industrial board are hereby required to add to the industrial code, as provided in sections twenty-eight and twenty-nine of the Labor Law, effective rules and regulations governing the installation, maintenance and effective operation in all industries and operations wherein silica dust or other harmful dust hazard is present, of approved devices designed to eliminate such harmful dusts and to promulgate such other regulations as will effectively control the incidence of silicosis and similar diseases.

It will be noted that the provisions of this section are mandatory and that the industrial commissioner and the industrial board are required to adopt effective rules and regulations. Pursuant thereto, the New York Industrial Commissioner has proceeded to accomplish the purposes designed by the law. Before the promulgation of proposed rules and regulations, the Commissioner

has instituted surveys for the purpose of studying operating conditions in those industries in New York State where hazards exist, to determine the extent of the hazard and the effect of the proposed rules and regulations upon those industries that will be subject thereto. He has appointed code committees, whose representatives have been chosen from representatives of manufacturers, labor organizations, state departments, manufacturers of protective equipment, and industrial hygienists so that he may have the advantage of the experience and points of view of those who are best informed upon the problems thus presented.

The first code committee made a study of rock drilling and formulated a code for that industry which has since been adopted. A second code committee was appointed to draft a foundry code and that committee is presently engaged in its research. During the present fall and winter it will probably recommend the formal code to the board, which will then be adopted. There are indications of the appointment of other code committees for those industries wherein hazards exist. These code committees conduct public hearings and then promulgate rules and regulations for the protection of workmen in certain specific industries. When adopted, the code becomes law and must be complied with by the particular industries that are subject thereto within the state.

Of similar nature is Section 39 of the California Workmen's Compensation Law, Chapter 586, which provides as follows:

Sec. 39. The commission shall have power, after a hearing had upon its own motion or upon complaint, by general or special orders, rules or regulations, or otherwise:

(1) To declare and prescribe what safety devices, safeguards or other means or methods of protection are well adapted to render the employees of every employment

and place of employment safe as required by law or lawful order.

(2) To fix such reasonable standards and to prescribe, modify and enforce such reasonable orders for the adoption, installation, use, maintenance and operation of safety devices, safeguards and other means or methods of protection, to be as nearly uniform as possible, as may be necessary to carry out all laws and lawful orders relative to the protection of the life and safety of employees in employments and places of employment.

(3) To fix and order such reasonable standards for the construction, repair and maintenance of places of employment as shall render them safe.

These provisions enable the commission to require the installation of protective machinery and equipment or take any other steps that are necessary, in the commission's judgment, for the prevention and control of occupational diseases. It is apparent that provisions of this type are vitally important if the incidence of occupational diseases is to be controlled.

There are also provisions in the health, labor, and compensation laws of all the states that can be administered for the prevention and control of occupational diseases. It would appear to be desirable to assign to one state department or to a board of industrial hygiene the administration of those laws that relate to the protection of employees from the hazard of occupational diseases. Such a board, with trained personnel, could unify the activities of various state departments and eliminate duplication of supervision, inspection, and control that would inevitably result if such duties were undertaken by more than one state department.

FUNCTIONS OF BUREAUS OF INDUSTRIAL HYGIENE

Maintenance of Reporting System—

In most of the industrial states, there is at present no effective system for maintaining reports and classifications of occupational diseases. It is to be

regretted that the importance of this feature has been overlooked by those interested in the subject of industrial hygiene. The maintenance of such a system would be of material value to make known to state officials those industries wherein potential occupational disease hazards exist, so that effective methods for their control could be adopted. Furthermore, the reported diseases could be classified as to extent of disability sustained by the employee, and data could thus be accumulated that would constitute a valuable record for the purpose of determining the effectiveness of the state's program for prevention and the industrial cost occasioned by disease injuries.

Establishment of rules and regulations for the control and prevention of occupational diseases—

This is the most important function that could be served by the bureau of industrial hygiene. Prior to the adoption of rules and regulations extensive surveys and studies should be made of those industries where occupational disease hazards exist, for the purpose of determining the extent of such hazards and the peculiar operating conditions in given plants which gave rise thereto.

After the completion of its survey of given industries, the bureau could then formulate and recommend for adoption rules and regulations for the control of occupational disease hazards therein that they deemed necessary to promulgate an adequate and effective program of control. When adopted, such rules and regulations should have the force and effect of law. They should only become effective after opportunity for full public hearing, so that any industry that might feel aggrieved by their provisions could be heard and have the opportunity to obtain necessary amendments that the bureau might agree were desirable.

Maintenance of Factory Inspection Service—

Under the various state health, labor, and occupational disease laws, factory inspection has been assigned to different state departments for different purposes. For example, factory inspectors of state departments of health are concerned with matters of sanitation; inspectors of state departments of labor are concerned with the compliance of industry with particular labor laws, such as hours of labor; inspectors of the industrial commission administering the Workmen's Compensation Act, are concerned with the compliance of employers with safety provisions of the compensation law. Where inspection service is thus divided among several state departments, the inevitable result will be that one department will adopt the attitude that it will let some other department take care of a certain type of inspection. The bureau of industrial hygiene could unify such factory inspection service as would be necessary to control industrial disease hazards effectively in the industries within the state. With proper inspection service occupational disease hazards would be discovered, called to the attention of the employer, and remedies for the conditions found.

Every effort should be made to assist industry in the solution of objectionable methods of manufacture that may tend to cause occupational disease hazards. There are many industries that do not have the personnel, equipment, or necessary technical information to understand the extent of the disease hazards in their plants or to install effective methods for their control. The department should assist such industries to correct faulty operating conditions, which could be done at a minimum of cost to the state. Experience has indicated that the greatest number of occupational disease hazards are not within the large industrial plants, operated by

companies that are financially able to perfect their methods of control, but do exist in the smaller units of production where capital resources are not available for the necessary engineering control. Such industries would welcome the bureau's assistance to minimize their hazards effectively and, with intelligent direction, many of the existing hazards could be eliminated at a minimum of cost.

CONCLUSION

Occupational disease compensation laws are the result of definite economic need to afford to injured employees adequate compensation for injuries they have sustained during the course of employment. At the time of their enactment employers have been concerned about the additional cost to which they have been subjected, but to date it does not appear that these laws have placed an unjust burden upon industry. It is to be hoped that employers as a group will cooperate in the administration of these laws. It is too early to predict whether or not that administration will be successful, but if they fail to accomplish the purpose for which they are designed, they should fail because of their inherent defects and inequalities, and not because of the attempt by employers to avoid the imposition upon them of costs for compensating injuries resulting from the operations to which their employees have been subjected.

Those of you who have made special studies of occupational diseases know and appreciate the problem that these laws present to industry. We also know from experience that the cost of prevention of injuries, be they caused by accidents or occupational disease, is but a small part of the potential liability imposed by law for compensation. It is good business today for employers to prevent, rather than to compensate occupational disease in-

juries, and I hope that in the future, prevention so that compensation will primary emphasis may be placed upon not be necessary.

DISCUSSION

C. O. SAPPINGTON, M.D., DR.P.H., F.A.P.H.A.

Consulting Industrial Hygienist, Chicago, Ill.

EVERYONE doubtless agrees with the ideas presented in Mr. Waters's excellent paper, but there are certain difficulties that we may discuss to advantage. We should keep in mind among other things, that—

1. The successful administration of these laws involves an intimate knowledge of the intricate associations of employment, disease, and disability—and what is of equal importance, the establishment of cause and effect relationships.

2. Many of the difficulties arising thus far have been occasioned by a belief in the fallacy that methods used in reference to accidental injuries were also of use here. The administration of the legal problems of occupational diseases is much more complicated, especially as to etiology, diagnosis, and differential diagnosis.

3. The use of vague and indefinite wording in our terminology and definitions, and in the laws, breeds controversy. We commonly speak of compensation for occupational diseases—*diseases* are not compensable but *disability* is—the theory of the law is that the employee is compensated for disability which incapacitates him for his work. This is but one example of common loose usage.

4. There are and will continue to be (to borrow a phrase from Dr. Nau) "chiselers on both sides."

There have been many attempts to define the term occupational disease with some fairly good results from these attempts; but we have to remember that whatever definition may seem to be satisfactory medically, must eventually be construed by the courts. The language of the court in *Goldberg vs. 954 Marcy Corporation* hardly leaves room for doubt as to what is legally meant by the term "occupational dis-

ease." Of course there would be no necessity for such construction where the so-called schedule system of naming the diseases is in effect.

I am in hearty agreement regarding the suggestion of the appointment of medical boards, especially in reference to the *competency, impartiality, and non-political affiliations* of the personnel composing them. Let us not however, overlook the fact that such men are unusual, and furthermore it should be emphasized that the tenure of office should be secure and the financial consideration commensurate.

The technical problems assignable to a medical board are obviously of such nature that they cannot be appropriately handled by non-medical persons. You will recall that Kessler made some statement such as this in his book *Accidental Injuries* in 1931.

The industrial hygiene bureaus have done very effective work in the several states. A reporting system would be of tremendous importance to the industrial epidemiologist, but we must first convince the employer that he will not be penalized if he reports his cases regularly.

Since the time is far too short for the adequate and detailed discussion which Mr. Waters's excellent paper deserves, may I make the following suggestions for the thoughtful consideration of the officers and the Section Council:

1. The advisability of the creation of a medical board committee especially for the

purpose of studying the functions of medical boards and supplying a list of qualified physicians in the various states

2. The advisability of the creation of a legislative committee for the purpose of advisory work in reference to the formation and administration of laws and codes.

Legislators, administrators, and allied workers need adequate professional

advice and guidance. It is time that we threw off our reaction of shyness to the important medico legal phases of this question. Surely no other group has been so close to the various developments in this field and certainly we have a definite responsibility to the public to make our knowledge and experience readily available.

Water-Borne Outbreak of *Brucella Melitensis* Infection

A. W. NEWITT, M.D., C.P.H., T. M. KOPPA, M.D., C.P.H.,
AND D. W. GUDAKUNST, M.D., D.P.H., F.A.P.H.A.

*Director, Bureau of Epidemiology; Epidemiologist, Bureau of
Epidemiology; and Commissioner; State Department
of Health, Lansing, Mich.*

AN outbreak of at least 80 cases of brucellosis with 1 death occurred on the campus of Michigan State College, East Lansing, during December, 1938, and January, 1939. All persons attacked were either students in bacteriology or were associated with the bacteriology building during December. In the basement of this building there is a laboratory devoted to the study of brucella organisms and the production of "brucellin" and other materials for diagnosis and treatment of brucella infection. Prior to February 4, on which date the authors were requested to participate in the investigation, it had been demonstrated by the college authorities that several persons were infected with *Brucella melitensis*, giving positive blood cultures.

DIAGNOSIS

The majority of patients gave a his-

tory of an onset with chills, severe headache, and intermittent fever, followed in a few days by increasing weakness, general myalgia, anorexia, insomnia, nausea, constipation, high fever, and delirium. In several there was a particularly troublesome bronchitis resembling that associated with influenza. There were some subclinical or latent cases with a history of only transitory malaise or no symptoms at all, discovered only by laboratory examinations. A few of the latter had positive blood cultures but gave no history or evidence of being ill. Confirmation of diagnosis was available for the 80 cases reported. A summary of the laboratory findings is shown in Table I.

EPIDEMIOLOGY

The distribution of the cases by dates of onset is shown graphically in Figure I.

TABLE I
Laboratory Findings

<i>Blood Culture Br. Melitensis</i>	<i>Agglutination</i>	<i>Skin Test</i>	<i>Phagocytosis</i>	<i>Totals</i>
X	X	X	X	35
	X	X	X	40
		X	X	5
Totals 35	75	80	80	80

FIGURE I

Eleven gave a history of having had chills, headache, and fever during the Christmas holidays and several students appeared at the college hospital for treatment on the day classes were resumed after vacation. The onset of undulant fever is characteristically insidious and many of the patients were uncertain of the actual date on which illness began. There is evidence, however,¹ that the incubation period varies widely and this probably accounts for the distribution shown in Figure I. There were 210 students enrolled for laboratory courses in bacteriology during the first semester, divided into 8 classes, all taking the introductory course and working with non-pathogenic bacteria exclusively. These classes worked in the laboratories on the second and third floors of the build-

ing on the days and time schedule indicated in Table II.

It will be noted that frank clinical illness was present in 37, and 28 were latent or subclinical. The attack rate varied with each class but out of a total exposure, in the regular laboratory classes, this rate was 30.9 per 100. Only one clinical case occurred among students in classes 2 and 3, but no information could be obtained from college authorities relative to laboratory data as to whether it was obtained for the members of these classes.

In addition to the 65 cases in the regular classes 15 other cases occurred. Ten of these were students in other courses who used the same laboratories as the regular students for special assignments in parasitology, poultry pathology, etc., one a plumber who

Totals			210	37	28	30.9

worked in the building; one a stenographer employed in a library on the second floor; one a stockroom attendant; one a student who paid social visits to a friend in one of the regular classes; and one a salesman who made but one visit to the building on December 13.

The history of this salesman is worthy of special comment. His date of onset was January 14, making an incubation period of 32 days. He went to bed January 19, and a definite diagnosis was made February 6. A blood culture taken February 6 showed *Brucella melitensis*. It was thus quite definitely established that the exposure of the patients took place about the middle of December.

Every case found to be infected with Brucella melitensis had been in the bacteriology building during the month of December.

Complete histories were obtained on all clinical cases. None had had any contact with goats or goats' milk. There was no correlation in regard to living quarters, milk supply or other

dairy products, restaurants, banquets or dinners. All evidence pointed to a source of infection which could only have been present in the bacteriology building and common to all who became infected.

Only a few of the patients had ever been in the brucella laboratory in the basement. There was no evidence that any of the cultures of brucella organisms from that laboratory had been taken to the laboratories used by the students. One possible medium which could have been a disseminator of the bacteria was water through the service within the bacteriology building.

The building is quite old and unsuitable architecturally for its purpose. Adaptation of the plumbing system to meet the demands of greatly augmented numbers of students during the past several years has greatly exceeded the capacity of the service. (See Figures II and III). It will be noted that the building's water supply is obtained from the college distributing system through a $1\frac{1}{4}$ inch service pipe approximately 50 feet long. Immediately

FIGURE II

inside the building there is a T coupling diverting the water into two 1 inch lines which extend around the building in opposite directions but do not reconnect. One inch risers serve the first, second, and third floors.

It was a custom of the brucella laboratory to place discarded cultures contained in Petri dishes and culture tubes in copper containers of about 1 cubic foot capacity. These were packed full, a tight fitting cover adjusted, and placed in an Arnold sterilizer. At the end of 1 hour's exposure to steam the dishes were removed, media scraped out, and the glassware washed in a nearby sink. As a test of the effectiveness of this sterilization we carried out the following procedure: On removal of the copper container after 1

hour it was found that the glassware could be comfortably handled immediately and that the agar media was not even melted. It was obvious that the method was entirely inadequate for sterilization of cultures.

The custom followed in washing the glassware was as follows: After the media was discarded the glassware was put in a large dishpan in the sink, the dishpan filled with water, and after a period of soaking the glassware washed. A piece of rubber tubing connected to the faucet was used to prevent breakage. When the dishpan was filled this tubing extended below the surface of the water in the dishpan. The possibility of siphonage if a negative pressure obtained in the water system was apparent.

FIGURE III

DEMONSTRATION OF SIPHONAGE

By opening several faucets in the basement a negative pressure was produced in the faucet at the sink where the glassware was washed. A pressure recorder on the third floor showed a negative pressure equivalent to 2 inches of mercury when all outlets in the basement were allowed to remain open. A solution of fluorescein was placed in a container in the sink used for washing glassware and after a negative pressure was produced at that point the dyed water was siphoned into the water system. After the dye had reached beyond the riser pipes to the upper floors the pressure was again returned to positive, and green water was obtained from every outlet in the building.

Referring to Figure III it will be noted that one of the riser pipes supplying the third floor is connected with the line supplying the sink where the glassware was washed. This allowed for more direct water communication between this sink and the third floor laboratory. Considerably more pipes would need to be traversed by contaminated water to reach the first and second floors. This fact may have been

responsible for the higher percentage of infected students among those using the third floor than among those using the second floor.

A new sink and 2 autoclaves were installed in the building during December. The water main outside the building had been tapped for a service to a new building nearby. Thus, in addition to the possibility of negative pressure being created by the simultaneous opening of a number of outlets in the building, there were additional possibilities when the water was shut off during these installations.

SUMMARY

1. An outbreak of 80 cases of infection with *Brucella melitensis*, with 1 death, occurring at Michigan State College, East Lansing, Mich., is reported.

2. All cases occurred in students and others using a bacteriology building which contains a laboratory that handled large numbers of brucella cultures.

3. A faulty technic of sterilization of discarded cultures was demonstrated.

4. Inadequate and faulty plumbing was found in which siphonage could be produced from the point where contaminated glassware was washed.

Vitamin D Potency of Human Breast Milk*

ROBERT S. HARRIS, PH.D., AND
JOHN W. M. BUNKER, PH.D., F.A.P.H.A.

Assistant Professor of Nutritional Biochemistry, and Professor of Physiology and Biochemistry, Massachusetts Institute of Technology, Cambridge, Mass.

FOR the prevention and cure of rickets in infants, human breast milk is admittedly superior to cow's milk. One would naturally assume this superiority to be based on a larger content of vitamin D in breast milk. Although quantitative data have not

hitherto been available, there are three investigations which indicate how little vitamin D breast milk contains, for no evidence of healing in rachitic rats was observed after feeding the quantities of human milk shown in Table I. Likewise, no evidence of healing was

made experimentally rachitic on the Steenbock 2965 ration. It appears, therefore, that since none of the above feedings of breast milk, or its fat, induced recognizable healing, there is evidence that mother's milk does not contain as much as 10 USP XI units of vitamin D per quart.

The investigation being reported was undertaken to determine the vitamin D potency of winter breast milk.

EXPERIMENTAL PROCEDURE

Sixty quarts of breast milk from wet nurses were obtained through the coöperation of the Boston Dispensary. Cream was obtained by passing this milk through a home-sized De Laval Cream Separator. Ten gm. of this cream, containing 20 per cent butter fat, produced no healing (Table III) when fed in the rachitogenic diet of each of 4 rachitic rats (20030-33) over a period of 6 days, while 20-35 gm. portions produced varying degrees of healing when fed 8 other rats (20034-41).

The remainder of the cream was extracted with four successive portions of anhydrous ethyl ether and the solvent was removed in vacuo under a stream of carbon dioxide. Graded portions of this ether-soluble fat were fed in the diets of each of 5 rachitic rats (20700-04) over a period of 6 days. The animals readily ingested quantities up to 10 gm., this latter amount producing definite rachitic healing (Table III). The animal fed a 15 gm. quantity showed rachitic healing but failed to gain in weight during the 12 days required for consumption of the supplement.

It is likely that the large feeding of fat prevented an accurate assay. Therefore, the remainder of the butter fat was saponified with 10 per cent aqueous potassium hydroxide and the ether-soluble fraction of the non-saponifiable material was fed in graded amounts to another series of 8 animals during a period of 6 days. One gm. of this material was equivalent to approximately 2,900 cc. of milk.

TABLE IV

Antirachitic Effect of Non-Saponifiable Fraction Prepared from Breast Milk Butter Fat

21342	.255	730	2.0
21343	.255	730	2.0

The results (Table IV) of the assays of this non-saponifiable material indicate that an equivalent of 730 cc. of human milk contain 3 USP XI units of vitamin D. The potency of the breast milk was therefore of the order of 4 USP XI units per quart.

DISCUSSION

The 15 gallons of breast milk used in these experiments, gathered during December, 1937, and January, 1938, constitute the largest, and therefore most representative, sample of human breast milk ever subjected to bioassay at one time. To conduct this assay it was necessary to prepare the non-saponifiable fraction of the milk fat since a rat will not consume enough breast milk or butter fat daily for a precise assay.

The results indicate that the milk from women in an urban community during the winter months contained not over 4 USP XI units per quart. It has been reported that cow's milk during the summer contains between 23 and 36 USP XI units per quart.

Whence, then, the greater power of breast milk, even in the winter, to protect the human infant against rickets more adequately than modified summer cow's milk? In the bottle feeding of the very young infant, cow's milk is customarily diluted with an equal volume of water. Such modified milk has a vitamin D content of at least 11

USP XI units per quart—nearly 3 times that of human breast milk. As the infant grows and formulae are changed, this disparity widens. The explanation lies elsewhere than in the vitamin D content.

Previously,³ we reported that the milk from mothers fed metabolized milk contained an equivalent of 21 USP XI units per quart. On the basis of the present finding, it may be seen that the vitamin D content of breast milk can be increased at least five-fold.

CONCLUSIONS

1. A composite sample of 15 gallons of human milk contained only 4 USP XI units of vitamin D per quart.

2. The antirachitic superiority of human milk over cow's milk in infant feeding cannot be attributed solely to the quantity of vitamin D which it contains.

3. It is possible to increase the antirachitic potency of human milk at least five-fold by feeding metabolized milk to the lactating mother.

Industrial Hygiene Codes*

JAMES R. ALLAN

*Assistant Manager, Industrial Engineering and Construction
Department, International Harvester Company, and
Chairman, Industrial Hygiene Codes Committee,
American Foundrymen's Association, Chicago, Ill.*

INDUSTRIAL hygiene codes in this discussion have to do with rules for the control of occupational disease exposure in industry.

All are familiar with the numerous safety codes prescribing rules and methods for the prevention of industrial accidents. Industry generally became safety minded years ago and set up rules and safe practices for the elimination of accidents, because the dangers of hazardous practices, devices, and operations were quite obvious to the average layman, and the effect of an accident was at once evident.

Unfortunately, it has only been in recent years that we began to realize that there were other occupational hazards considerably less obvious than accidents that should receive intelligent attention, particularly occupational diseases arising out of and in the course of employment. One only has to go back a few years and review the various state labor laws or industrial codes and note the very limited number of rules pertaining to health hazards, and even in these few cases the rules were largely limited to certain requirements for grinding and polishing operations.

Taking for example the few state requirements for safeguarding grinding

and polishing operations, it was found that no two states agreed anywhere in reason on the air volume or air velocity required for exhaust equipment. The extremes varied from a maximum of 9,000' per minute velocity in the branch pipe to a minimum of 2" static suction as measured with a U-tube manometer gauge.

Within practically the past 6 years, we have become somewhat occupational disease conscious, brought about principally through the hysteria of the silicosis phase of the question. I say hysteria advisedly because it very nearly amounted to sabotage of certain industries from some sources, although it cannot be denied that hazards in many forms existed. At any rate it was obvious that we must know more about our problem and the measures necessary for the effective control of occupational diseases.

Some of the various branches of the industry, particularly the foundry industry, felt that the only way to obtain an intelligent understanding of their specific problems was to start an educational program and openly discuss the various phases of disease exposures in technical meetings and cooperate with various bodies attempting to suggest remedies to the industry. It was at once apparent that there was a great divergence of opinion as to the proper measures for control. The foundry

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

industry therefore undertook the task of studying and setting up industrial hygiene codes applying to all phases of activity wherein there was an exposure to an occupational disease hazard. I suppose there is no industry that has so many ramifications and such a variety of operations wherein certain control measures may be required as the foundry industry and its allied departmental activities. A good start has been made in the developing of such codes and it is the purpose of those engaged in drafting the hygiene codes to continue their efforts until the whole industry has been covered.

In starting the task of formulating the codes, it was at once apparent that we lacked fundamental data for a great deal of our problem. True, we had the help and experience of the best informed industrial medical men, which was of value in pointing out the danger points to be safeguarded. With the knowledge gained from the industrial medical authorities as to what we should set up our codes for, we had our starting point.

The first thing we had to do was to develop a code prescribing a more accurate method of measuring and determining the flow of air in exhaust systems so that the vendor of equipment could intelligently meet the specifications and the plants had a prescribed method of knowing how to determine the functioning of the exhaust systems. Another code developed had to do with the fundamentals of design, construction, operation, and maintenance of exhaust systems. Surprising as it may seem, few people had any fundamental knowledge of design, and most systems were laid out by rule of thumb methods. Considerable research work was necessary, and we found out that the friction formulae for resistance of air flow in straight pipe that we had all been using were very much

in error; also, the resistance losses in round elbows that had been accepted practice were at considerable variance with actual facts disclosed by research.

A code was developed applying to exhaust systems for grinding, polishing, and buffing equipment. This code attempts to put into orderly arrangement the various sizes of connecting branches with relation to wheel sizes, as well as specifying minimum air velocities.

Still another code has to do with the ventilation of the various types of tumbling mills. This was a difficult problem on account of the fact that the vendors had been building mills for years, and pattern equipment existed that could not be scrapped without imposing a severe price handicap to prospective purchasers of equipment.

Codes are under way for many additional types of equipment and processes in the industry.

In addition to equipment and process codes, there are codes being developed to control the specifications covering the toxic properties of certain commodities that are rather universally used in the industry, as well as prescribing safe methods for the use of such toxic materials.

In all of the code material providing for the suppression of dusts, gases, fumes, and vapors, the requirements are based on the best known engineering practice that exists at the present time. Dust counts are not recognized in any of the code material, for the reason that dust counts are still a very controversial subject and mean little or nothing to a great many plants that do not have highly trained experts familiar with dust count equipment and technic.

In the foundry industry, we believe that we have some definite facts about the development of industrial codes, and from these facts have adjusted the policy of our code committee activity. Some of these facts are:

1. One has to be occupational disease minded to comprehend the necessity for the development of industrial codes.

2. The people best qualified to develop a practical and intelligent industrial code are employers and users of equipment, because they understand all limiting factors of equipment and processes.

3. Vendors of equipment and processes should be party to the code development in order to give the advantage of their experience and that they may adjust their viewpoint to that of the user of the equipment to obtain maximum protection.

4. Make use of all pertinent information and personnel from recognized units, such as the U. S. Public Health Service, where there is a background of research and investigation of the phases of the problem under consideration.

The beneficial effects of having good industrial codes are manifold and some of the more important items are:

1. They provide the industry with the latest and best engineering data for the control of hazardous pieces of equipment, operations, or processes.

2. They put in the hands of the small employer who does not have an engineering staff, technical information for his use in order to specify types of equipment, exhaust systems, etc.

3. They put the vendors of equipment and systems on the same specification basis as to the requirements of the prospective purchaser.

4. Available good industrial codes make it possible for the legislative bodies to have up-to-date information available for their consideration and deliberation.

5. The proper observance of the requirements of industrial codes in controlling hazardous exposure will result in a large decrease in occupational diseases and compensation paid out.

With a good code that is observed, hardly any industry need pay out more than one cent for compensation per \$100 of pay roll. The company I am associated with, we are proud to say, very early recognized its moral obligations with respect to hazards. For the year 1937 they paid out approximately $\frac{1}{4}$ mill per \$100 of pay roll, and a good part of this money consisted of dermatitis claims.

One cannot be closely identified with the development of industrial hygiene codes without forming some very definite opinions as to what would constitute an ideal set-up for state industrial hygiene codes. When a state passes acts of legislation requiring certain minimum specifications and engineering details for the control of an occupational hazard, difficulties are at once encountered because there are always exceptions to the rule due to the tremendous variations of performing operations and in operating equipment. It is impossible to conceive or provide for all of these variations in a law. Hence a certain amount of confusion arises immediately. The same general argument holds good for state industrial codes which have the force and effect of law, although it is usually easier to modify industrial codes by means of public hearings than it is to get a legislature to make changes. A better method is to have an enabling act of legislature providing for a state supervising or enforcing agency that shall be charged with the duties of formulating rules and regulations for the protection of the health of workers and also for the enforcement of such requirements. The rules and regulations so formulated should be of a general requirement character only and not specific as to physical dimensions and engineering details.

One of the principal requirements of the general code shall be that of the supervising department having the power to adopt and apply reasonable and up-to-date physical engineering details and data more or less in the form of an appendix to the general code, but definitely not a part of the code, so that it will not have the force and effect of law. This plan makes it possible for the supervising department to have some discretionary power to meet the unusual situation as it arises, and further permits changing the en-

engineering requirements as better information and knowledge become available on the subject. This method outlined would permit the supervising agency to keep abreast of the times, and would eliminate numerous handicaps and confusion.

It is our definite recommendation based on the experience we have had in the foundry industry, that every industry should develop a code for the control of occupational disease hazards.

Having developed such a code they should make every attempt to get that industry to apply the code to its hazardous operations. This will aid materially in bettering the working conditions by promoting good housekeeping, it will prevent disability through removal of hazardous exposures and result in operating economies through lowered compensation paid for occupational disability and through improved working methods of operation.

DISCUSSION

O. T. NELSON

Building Engineer, Industrial Commission, Madison, Wis.

Mr. Allan is to be commended on his paper and on the concise manner in which his topic has been handled. The subject is a large one and extremely difficult to handle in a short presentation.

I am quite familiar with the particular foundry code which has already been developed by a capable committee headed by Mr. Allan as chairman. While this code is not entirely in agreement with our own Wisconsin requirements, particularly as to air velocities, I feel that it is an excellent treatise and can well be invaluable to the foundry industry. It may also serve as a guide to other industries in preparation of similar codes for their own purposes. This code places in the hands of the foundryman complete information relative to the removal of hazardous dusts, fumes, vapors and gases and gives all of the information necessary for a complete design from the isolation at the source of the hazard to the final collection or method of disposal.

This code, which really can be classed as a textbook, is of necessity entirely different from the type of codes or rules

which should be prepared by governing bodies, such as state organizations. These codes should not in any sense be of the textbook form, but should be so designed as to act merely as a guide to the competent designer or engineer who has both the experience and other necessary design data on hand for his design. These codes need only set up detailed standards as to general requirements and as to the results to be accomplished.

Mr. Allan points out the difficulties which are encountered when a state legislature passes laws requiring certain minimum specifications and engineering details for the control of occupational hazards within its respective state. He is entirely correct in his viewpoint, as such a procedure sets up a legal requirement which cannot be changed except by legislative repeal or amendment. It is far better to have an enabling act passed which designates to some proper and competent administrative body the power to draw up and set forth the rules or orders which may be necessary to provide proper working conditions.

Such a situation exists in Wisconsin,

where the legislature about 27 years ago created the Industrial Commission and, among other duties, empowered this commission to prescribe, modify, and enforce orders for the protection of life, health, safety, and welfare of employees and frequenters of public buildings and places of employment within the state.

Among the publications which have been issued covering various phases of safety and sanitation is the industrial hygiene code entitled "General Orders on Dusts, Fumes, Vapors and Gases." This code contains general fundamental requirements for protection, setting up necessary face velocities and also the required minimum velocities through the branch ducts which are based on U-tube suction readings. Such a method, rather than the pitot tube method was deemed necessary due to the fact that check-ups of exhaust systems are made by the general field deputies of the commission, and it would be impractical to equip them with any more elaborate equipment for this purpose than a U-tube. Our code further specifies the minimum gauges of metal to be used, indicates the minimum sizes of main ducts in proportion to the entering branches, provides for the maximum angle of entrance for branch ducts, makes provision for proper disposal of the entrained material, and in general is so set up as to be a guide to the

engineer or manufacturer in the design of his exhaust system.

These orders, however, are flexible in that they can be modified without legislative action in special cases. We have found, during the more than 6 years that this code has been in effect, that the requirements which have been set up are proving quite satisfactory for the general run of manufacturing plants. Occasionally, however, a situation arises in connection with certain processes where modification is necessary, and in such cases this modification is granted. There are also other situations where careful engineering design is provided and where exceptional maintenance and supervision of the equipment is furnished which may also permit reduction in air volumes and velocities. Such a modification was granted to Mr. Allan's company for its Milwaukee plant and was definitely based on its engineering design and the particular maintenance and supervision which is provided at all times.

It has not been my intention to advertise Wisconsin's code, but merely to point out that individual state codes can be provided which are sufficiently flexible to take advantage of good design and to progress as better information and increased knowledge become available on the subject. I believe that this coincides quite well with the ideas expressed by Mr. Allan.

Vital Statistics of the Pueblo Indians*

J. H. WATKINS, PH.D., F.A.P.H.A., E. H. PITNEY
*Department of Public Health, Yale School of Medicine,
New Haven, Conn.*

AND

S. B. D. ABERLE, M.D.
United Pueblos Agency, Albuquerque, N. M.

THIS paper deals with the demographic facts available for one group of North American Indians, the Pueblos of New Mexico. These Indians constitute a population of about 12,000 living on 19 reservations along a 300 mile line from Taos in the north to Zuni on the western border. For centuries they have existed in small compact communities, cultivating the fertile strip along the banks of the Rio Grande and other rivers. Because of their settled agricultural and communal life their customs and habits are more highly stabilized than those of other Indians. Comparatively little migration has taken place between the Pueblos and other racial groups. They have maintained themselves as tightly bound, largely self-governing groups, and while it is impossible to claim for them absolute purity of blood the findings of the United States Census for 1930 show that the two linguistic stocks with

which we shall deal, the Keresan and Tanoan, assert themselves to be 98 and 95 per cent respectively, "full blood."

THE RECORDS

Since the Spanish conquest the Pueblos have been under the religious direction of the Roman Catholic church and the records of baptisms and burials are preserved in their parishes. During this period censuses varying in completeness were made at irregular intervals. Following the American occupation of New Mexico and the subsequent appointment of an Indian Agent in 1849, official population counts were made occasionally until about 1900, estimates being submitted to Washington in the intervening years. Between 1900 and 1910 a more thorough system of recording pueblo membership was introduced. This took the form of a census roll for each pueblo, giving the details of name, age, sex, family connection and degree of blood for each member of the pueblo. These were revised from year to year by field employees of the Indian Service who necessarily used the records in their daily work and

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

had the opportunity to consult with the Indians as to their accuracy. The revisions consisted of additions to the pueblo by birth and immigration and removals through death and emigration.

The rolls, although revised annually, had never been corrected by means of an actual enumeration until 1936 when a canvass was made for this purpose by Indian Service and Soil Conservation Service employees. In addition the records were submitted to the governor and council of each pueblo for further verification and for certification as to their accuracy. The fact that these census rolls, which are believed to be as accurate as it is possible to make them, differed in no important respect from the earlier ones, supports our assumption that the old rolls were substantially correct except possibly for the statements as to degree of blood.

Supplementary to the revisions of the census rolls, the standard birth and death certificates of the U. S. Bureau of the Census have gradually come into use. While they are signed by physicians for the relatively few hospital deaths, the field nurse is responsible for the greater number. Therefore certification can be considered correct only as to the event of death and not as to cause.

In conjunction with the recently revised census roll a new system of collection has come into effect. Native enumerators have been appointed for each pueblo who receive a suitable fee for every report of a birth, death, marriage, divorce, or change in membership. Monthly reports are sent to the main office of the United Pueblos Agency together with birth and death certificates for which the nurse is still responsible. Upon receipt at the main office, the monthly data are incorporated into what is essentially a population register. A master card for each member of every pueblo has been prepared and placed on file which contains all

the information given on the 1936 census roll, *i.e.*, name, parentage, relation to household head, address, sex, date of birth, legitimacy, blood, and tribe, with provision for changes in such items as address and relation to household head. In addition, space is allowed for a full record of the events of marriage, childbirth, and death as they occur. When this system has been perfected its supervision by one clerk will permit of a complete and continuous check on the approximately 12,000 Indian inhabitants of the pueblos.

The demographic aspects presented here relate to 17 of the 19 pueblos, for which practically complete censuses exist. The data for Santo Domingo and Zuni have been excluded, the first because of native resistance to outside interference and the second because of similar difficulties as well as the relative dispersion of its population. The 17 pueblos contained altogether 9,104 persons in 1936. They range in size from Laguna, with 2,367, to the practically extinct Pojoaquè, with 20 persons. As we cannot establish accuracy for natality and mortality reporting prior to 1926, mortality and natality rates have been computed for an 11 year period only, 1926-1936, inclusive. The population data have been taken from the census rolls, and those for natality and mortality from the rolls as well as from the existing birth and death certificates. Assistance in certain phases of the tabulation was secured from the Carnegie Institution of Washington.

POPULATION GROWTH

Chart 1 gives the population curve of the 17 pueblos during the period of American control. Only those population figures are shown for the period before 1911 upon which some degree of reliance can be placed.

The pueblos, previous to 1900, contained between 5,000 and 7,000 persons.

CHART 1

Since then a gradual increase has taken place checked only by the influenza epidemic of 1918-1919. This upward trend cannot be entirely accounted for by the improvements in enumeration and is due to an actual population growth. Recent newspaper publicity on the growth of the Indian population of the United States since 1900 gives tardy recognition to this trend, true not only of the Pueblos, but also of other Indian tribes.

POPULATION DISTRIBUTION BY AGE AND SEX

The 1936 age-sex diagram of the population of the 17 pueblos, together with those of whites and negroes for the United States in 1930, is shown in Chart 2. The Pueblo diagram demon-

strates a high proportion of children in the population, and a smaller percentage of females over 35 years of age as compared with males. In the latter respect the Pueblo Indians are similar to the Negroes.

TRENDS OF NATIVITY AND MORTALITY

The trend of the birth rate, death rate, infant mortality rate, death rates of persons under and over 5 years of age, and the vital index are shown in Chart 3 and Table I for the years 1926-1936, inclusive. For this period the average annual death rate was 20.9 per 1,000 population, the birth rate, 38.0 per 1,000 population, and the infant mortality rate, 171.2 per 1,000 live births. The vital index was 185. The infant mortality rate, which appears to be slightly increasing, is the only annual series showing a trend. The increase, however, is not statistically significant, and we are inclined to attribute it to an improvement in recording infant deaths. In the earlier years when death certificates were not available, our use of the census rolls to determine the number of deaths would not reveal deaths which occurred before names could be entered. In a careful study of infant mortality in the

CHART 2

† per 1,000 live births

‡ (births x 100)/deaths

pueblos of San Juan and Santa Clara for the years 1925 to 1930, Aberle found the infant mortality rate to be above 200.

The difference between the birth and death rates, amounting on the average to an annual increase of 17.1 persons per 1,000 population, is sufficient to account for the change in population numbers since 1926, and can be presumed to be responsible for the increase between 1900 and 1926. But in the absence of natality and mortality data covering this latter period and due to the fact that it is improbable that the birth rate has increased substantially, we are led to regard a significant lowering of mortality during the period 1900 to 1910 as the factor leading to the increase in population. The explanation, we believe, lies in the change in the number and degree of severity of epidemics experienced by the Pueblo Indians. Quantitative information on this point is lacking, but the belief is borne out by early historical records and the annual narrative reports of the Pueblo Indian Agents. The latter,

published in the *Annual Reports of the U. S. Indian Service* up to 1906, and to be found in the government archives for subsequent years, comment upon the health of the pueblos. The occur-

CHART 3

rence of an epidemic was usually noted, with mention of the type of the disease and the pueblos in which it occurred.

The great smallpox epidemic of 1781 is classic in the history of the Southwest. Bancroft records that among the Pueblo Indians 5,000 deaths occurred in that year out of an enumerated 9,000 in 1760. Bloom has translated the accounts of the introduction of vaccination in New Mexico in 1804 and relates that in 1805 a count of those not having had smallpox showed that in the pueblos and Spanish settlements of central New Mexico over two-thirds of the children under 12 had had the disease. The report did not record numbers for men and women because, the *alcalde* states, ". . . in all this jurisdiction no one has been found who is more than 6 years of age who has not suffered from the sickness of smallpox." The subsequent wide-scale program of vaccination was not maintained, however, for between 1837 and 1840 a combined siege of smallpox and typhoid is recorded as having killed one-tenth of the inhabitants. As late as 1889 the Indian Agent reports: "At a few of the pueblos there has been a great deal of sickness during the past year . . . and it is estimated that about 400 have died during the past year at said pueblos, smallpox and diphtheria being the principal diseases." In the two following years these diseases spread to other pueblos, causing further fatalities. In 1894 and 1895 spinal meningitis or spotted fever caused a considerable number of deaths in two of the pueblos.

During the next decade, however, the story changes. In 1903-1905 diphtheria appeared again but the introduction of antitoxin was successful in checking mortality from the disease. During the latter half of the decade no record of serious epidemics has been found. Vaccination of the pueblo school population was reported to have been carried out in 1896, but in 1913-1914

a complete vaccination of the pueblo population was ordered. Shortly after, smallpox broke out among the Navajos to the west and subsequently spread over New Mexico into the Spanish population in the region of the pueblos but not to the vaccinated Pueblo Indian population. Since 1900 only one epidemic of a size markedly affecting the population curve has occurred, the influenza epidemic of 1918-1919. As to other epidemics we find record, for example, that measles and diphtheria caused the deaths of approximately 100 children in the pueblo of Santo Domingo in 1915. Other notes regarding the appearance of diphtheria, measles, scarlet fever, whooping cough, and influenza appear in the narrative reports, but now the epidemics are measured in numbers of cases rather than deaths, and frequent comments on the mildness of the diseases are found. Trachoma and tuberculosis have long been of serious concern among the pueblos. But the great epidemics of the 18th and 19th centuries no longer appear, thus making it possible for the disparity between the birth and death rates to manifest itself in population increase.

The decline in epidemic effects on mortality may be attributed to the following factors:

1. The establishment of day and boarding schools between 1870 and 1890 which brought the children of the pueblos under supervision.
2. The appointment of field matrons during 1880-1890 who, acting as instructors in housekeeping, brought new ideas of cleanliness.
3. The beginning about 1900 of the appointment of contract and staff physicians.
4. The practically complete vaccination of the pueblo population in 1913 and 1914, and the introduction of the use of diphtheria antitoxin.
5. The introduction of driven wells in the pueblos. In 1914 the first 3 of the pueblos were supplied with driven wells. These were of the approved type with tight casings and concrete caps and, by freeing the inhabitants from the necessity of using water from the

irrigation ditches for drinking purposes, were presumably effective in cutting down typhoid and dysentery.

With these 5 factors, all of which act, by human effort, directly against the effect of infectious disease, we must also include the change in character of smallpox and scarlet fever from severe to relatively mild forms, a phenomenon well known in the United States. Also the possibility exists that by the stringent forces of selection some degree of immunity to the diseases of the white man may have come to the Indian.

MORTALITY BY AGE AND SEX

The variation in mortality by sex and broad age groups for the 11 year period is shown by the rates (per 1,000 population) of Table II. Similar rates for the white and colored population of the U. S. Death Registration Area of 1930 are also given.

tive to the female, is 28 per cent higher as compared to 25 and 22 per cent for the whites and negroes respectively. The females exceed in mortality during the period of middle life. Aberle has previously shown that maternal mortality is high among Pueblo women and although we have no data on causes of death it appears that this factor, together with tuberculosis, may account for the excessive female mortality between 15 and 45 years of age.

In contrast with the whites and negroes, Pueblo mortality by sex shows for the Pueblo population a greatly excessive mortality at the younger ages, an excess which gradually diminishes with advancing age until, in the age group 25-44.9, the Pueblo rates lie between those for whites and negroes, and at the oldest age group, 65 years and over, Pueblo mortality is less than for either whites or negroes. The latter

Rates per 1,000 population

Comparing the rates for Pueblo Indian males with those for females we find that mortality among the males is considerably higher at ages under 5 and over 65 than among females. The higher death rate under 5 for males is also observed for whites and negroes, but for the Pueblos the male rate, rela-

difference is statistically significant between Pueblos and negroes but not between Pueblos and whites. A check on the accuracy of age-statements of Pueblo Indians over 40 does not indicate that over-estimation of age can account for the low mortality at these older ages. For an explanation of this

TABLE III

Average Annual Birth, Death and Infant Mortality Rates, Seventeen Rio Grande Pueblos, 1926-1936

<i>Pueblo</i>	<i>Population Average 1930-1932</i>	<i>Birth Rate</i>	<i>Death Rate</i>	<i>Infant Mortality Rate</i>
Acoma	1,044	38	16	142
Cochiti	286	48	28	166
Isleta	1,057	35	19	126
Jemez	637	45	32	221
Laguna	2,143	31	15	165
Nambe	128	39	15	55

Taos	706	33	16	130
Tesuque	119	53	31	174
Total	8,321	38	21	171

* Estimated

Birth and death rates per 1,000 population; infant mortality rates per 1,000 live births

indicated low old-age mortality, we are inclined to fall back upon the well worn explanation of the "stress and strain of modern life" as the factor producing higher mortality among whites and negroes. Not sharing the oil royalties of his Oklahoma brothers, without automobiles, and deprived by law of the use of intoxicating beverages, the Pueblo Indian can be said to lead a comparatively uncomplicated life.

MORTALITY AMONG INDIVIDUAL PUEBLOS

When the 11 year mortality data are subdivided by individual pueblos, chance fluctuation appears to confuse the picture (Table III). It may be said, however, that generally mortality rates significantly lower than for the pueblo group as a whole are found in those pueblos in which cash income is greatest, such as Acoma and Laguna, which receive employment from the railroad, and in Taos, the New Mexico

tourist mecca and artist colony. On the other hand, high rates appear roughly to be associated with pueblos with a minimum of cash income, such as in Cochiti, Jemez, Sandia, San Felipe, and Tesuque. The infant mortality rates of the pueblos of course vary widely, but it is interesting to note that a significantly low infant mortality rate (126) is recorded for Isleta, the pueblo only 12 miles from the medical and hospital facilities of Albuquerque, and in which an efficient and energetic public health nurse has functioned during the years for which we have data.

SUMMARY

Among races of record, the Pueblo Indian is almost unique in the United States in showing a high birth rate and death rate, neither of which has declined since 1926. The vital index appears to have exceeded and maintained a level over 100 since about 1900, which

has come about by the lessening of the amount of and the effect of infectious disease. However, the high mortality rate, especially at the younger ages, presents a challenge to continued and increased effort on the part of the sanitarians and members of the medical profession interested in the health of the Indian. We cannot consider here the many factors which, once controlled or improved, will yield beneficial results. Diet, further sanitary improvements, the betterment of the economic condition of the Indian, and an increase in medical facilities may be cited. Attention is already being turned to factors

such as these and if such efforts as are being made are continued without financial or political restriction we may expect to see results in a downward trend of mortality among the Pueblo Indians.

Newer Research Findings for Dealing with Syphilis and Gonorrhea*

CHARLES WALTER CLARKE, M.D.

Consultant, New York City Department of Health, Executive Director, American Social Hygiene Association, New York, N. Y.

IN the time at my disposal for the preparation and presentation of this paper, it is not possible for me to give a full digest of the advances made in the last few years in the scientific bases for the control of syphilis, gonorrhea, and other so-called venereal diseases. Important and impressive reports have appeared regularly in the literature and are available to all who wish to go exhaustively into these subjects. I would especially call attention to Padget and Moore's "Syphilis, A Review of Recent Literature," published annually.¹ It is well worth the time of any physician interested in this subject to study Moore's articles.

In 1936 there appeared an excellent report on our knowledge of the gonococcus and gonococcal infections written by Thomas and Bayne-Jones,² the result of 2 years' work by a joint committee of the National Research Council and the American Social Hygiene Association. This report has recently been brought up to date by Dr. Thomas in a project sponsored by the American Neisserian Medical Society and the U. S. Public Health Service. Numerous articles on "Lymphogranuloma Ingu-

nale" have appeared but, so far as I know, there has been no comprehensive summary, though interest has been keen and research active during the last 3 years; nor has there been any comprehensive survey of our medical knowledge of chancroid or granuloma inguinale.[†]

Since time limitations oblige me to choose a few items for emphasis in this presentation of scientific advances, I will briefly discuss what seems to me the most interesting and possibly the most important forward steps.

It is well that the most spectacular discoveries of the last few years have been in the treatment of the most neglected communicable disease afflicting mankind, the "step-child of medicine," the disease known by a

[†] Reference should be made, for the sake of completeness, to several important reports on the public health aspects of syphilis and gonorrhea. The report of the 1936 Conference on Venereal Disease Control, published by the U. S. Public Health Service, constitutes an excellent presentation of principles and methods of control of syphilis and gonorrhea. Clarke's report of the New York City Commission to Study the Control of Syphilis and Gonorrhea in Scandinavian Countries and Great Britain,³ and Harrison's report⁴ covering the same ground, and in addition Holland, give the facts regarding European progress. "Next Steps in Gonorrhea Control," in the July, 1938, issue of *Venereal Disease Information*, gives the latest ideas regarding the subject indicated. The May-June, 1938, issue of the *Journal of Social Hygiene* describes the status of social hygiene programs and activities, including syphilis and gonorrhea control in official and voluntary agencies throughout the United States.

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

dozen humorous nicknames, the infection that causes sterility, arthritis, blindness, and chronic invalidism, the most prevalent ailment excepting only the common cold—of course, I mean gonorrhea and other gonococcus infections. Recent discoveries have changed the outlook on the conquest of this ubiquitous disease. We need no longer fumble aimlessly with the colossal problem of gonorrhea.

Three highly important discoveries in the therapy of gonococcus infections have made this difference in the outlook. They are: the estrogenic hormone treatment of gonococcal vaginitis, discovered by Dr. Robert Lewis, of Yale; the fever treatment of gonorrhea to which many experimenters have contributed, including Kumer, Carpenter, Warren, Simpson, and Bierman; and most spectacular of all—sulphanilamide—with contributions by Foerster, Long, Bliss, Mahoney, Van Slyke, Thayer, Cohn, and others too numerous to mention here. All of these methods are still in the experimental stage but each has definitely proved its value under certain conditions.

All types of gonococcus infections were curable in most cases by the older methods, but treatment was tedious and often uncertain of results. Since gonorrhea is potentially infectious until cured, methods which give quicker results were desirable, both from the standpoint of cure and of prevention of spread of infection. The lack of such speedy methods of rendering gonorrhea non-infectious was one of the causes of apathy of health officers with regard to gonorrhea. The problem seemed both stupendous and hopeless to many. The vital thing in recent progress is that the newer methods of treatment shorten the time required for satisfactory results; that is, cure of the disease and cessation of spread of infection. The newer methods also give satisfactory results

in a larger percentage of cases treated.

Robert Lewis observed, as have many others, that girls having gonococcal vaginitis apparently "outgrew" their infection when they had passed through the anatomical and physiological changes collectively called puberty. The vaginal mucosa during puberty becomes thicker, tougher, and more resistant to infection. Lewis considered that if he could induce these changes in little girls having vaginitis, perhaps the infection would be cured. He found that estrogenic substances produced the desired change in vaginal epithelium first in experimental animals and then in girls; and that, as he anticipated, on discontinuing the use of the substance the vaginal mucosa returned to its normal infantile type with no deleterious residual effects and the gonococcal infection disappeared. It was later shown that probably not only the change in epithelium itself but the concomitant change in the pH of the vaginal secretion from the neutral or alkaline side to the acid side, brought about the cure of vaginitis. The estrogenic substance is now generally administered as a vaginal suppository.⁵ The treatment which seems most convenient and popular is a capsule or half a suppository containing the equivalent of 1,000 international estrogenic units inserted into the vagina daily at bedtime. This treatment is safe, has no deleterious effects, cures about 63 per cent of cases,⁶ is convenient for home treatment and saves the child from long periods of hospitalization. It constitutes an important advance in therapy, beneficial to the mental and physical welfare of thousands of infected little girls.

"Fever treatment" of gonorrhea is not new. The American Indians used the sweat house for the treatment of gonorrhea probably from the time they acquired this disease from the white man. Wagner Jauregg, in his early ex-

periments, noted that fever benefitted gonococcal urethritis as well as dementia-paralytica in his patients. Kumer,⁷ at Innsbruck, for more than 18 years has been treating stubborn cases of gonorrhea by means of malaria and has been obtaining excellent results, especially in women.

Many different means of producing fever temperatures for the treatment of gonorrhea have been used but they can be divided into the two groups of which typical examples are mentioned above; namely, physical means like the Indian sweat house, and physiological means like Wagner Jauregg's malaria. I once asked Wagner Jauregg what was his preference among the various methods of producing fever temperatures for the treatment of gonorrhea and syphilis. He replied, "Any kind of fever is good for these diseases, but all are not equally good for the patient nor equally convenient, controllable and safe." Unless methods have changed since I last studied this subject in Europe in 1935, malaria is still the method of choice where fever is used for the treatment of either syphilis or gonorrhea. In the United States, however, more attention has been given to physical means of elevating temperature. Among the most popular today are: (1) the Kittering hypertherm using hot moist air (just as the Indians do in their sweat houses); (2) radiant heat as employed in the cabinet devised by Carpenter and Warren; and (3) high-frequency shortwaves, and a combination of high frequency and diatherm as employed by Bierman.

The work of Carpenter and Warren⁸ is among the most outstanding in the use of artificially induced fever in the treatment of gonorrhea, because of the scientific method employed. They first isolate the strain or strains of gonococcus infecting the patient; they next determine the thermal death time of the particular strain at a temperature of

106.7° F.; they then place the patient in the cabinet, and under the most painstaking medical and nursing supervision they raise the patient's temperature to 106.7° and maintain it at this level for the indicated period of time; or, if this is found to be dangerous, for a somewhat shorter period of time. The great majority of patients (87 per cent) were cured, as determined by most careful clinical and bacteriological studies, after one treatment of 6 to 27 hours' duration.⁹

Other methods of fever treatment of gonorrhea are not so elaborate nor so scientific. They apply heat in one or more sessions in the fever cabinet for fixed periods of time and at fixed temperatures. It is significant, however, that all types of artificial fever treatment give good results in gonococcus infections.

What is the mechanism of cure of gonorrhea by active or passive fever temperatures? It may be that the temperatures attained kill the gonococcus. In the method used by Carpenter and Warren, the gonococcus may be literally "parboiled." It may be that fever stimulates the defense mechanism of the body or injures the gonococcus so that the defense mechanism can more effectively attack the invader. This is probably true of malaria treatment where very high temperatures are not attained but where results are excellent. The mechanism of cure may be some combination of these factors, or some other factor as yet unrecognized.

However fever therapy acts in the treatment of gonorrhea, it is a valuable addition to our armamentarium and has, I believe, come for a long stay, because: (1) It cures, even in one day, in many cases, where the Carpenter and Warren method is used; (2) it cures highly recalcitrant complications in many instances; and (3) used in conjunction with other treatment, it cures even a larger percentage of stubborn

cases. The disadvantages of the fever treatment are: (1) It is not without danger; (2) it is a very mean experience for the patient; (3) it requires hospitalization and highly specialized medical and nursing care; (4) and consequently, it is expensive but not relatively so when one considers the costs of surgical intervention in many complications.

Sulphanilamide is the name given by the Council on Pharmacy and Chemistry of the American Medical Association to "para-amino-benzene-sulphonamide" or "para-amino-phenyl-sulphonamide." Foerster, on May 17, 1933, made the first report of medical use of sulphanilamide when he presented to the Dermatological Society of Dusseldorf, Germany, the remarkable therapeutic results obtained by the administration of this drug in a case of generalized staphylococcal infection. Subsequently, sulphanilamide was tried by many others in Germany, France, Great Britain, and the United States, with continuously heightening interest on the part of the medical profession.

The therapeutic value of sulphanilamide may possibly prove, when at last its value is established, to be comparable with that of salvarsan, quinine, or other previously known specifics. The drug is given by mouth and by hypodermoclysis and sometimes intrathecally. Its mode of action is not understood but the suggestion has been advanced that sulphanilamide may dissolve the capsules of various cocci or in some way make them more vulnerable to bactericidal substances present in the serum.^{10, 11}

Apparently, sulphanilamide has specific value in the treatment of many coccal infections in humans. Not only the staphylococcus, streptococcus, meningococcus, and the pneumococcus, but also the gonococcus appear to be susceptible to the attack of this drug. Its scientific use in the treatment of gono-

coccal infections has not passed the experimental stage, though thousands of doses are sold daily over drug store counters without physicians' prescriptions. So far as serious studies have progressed, they indicate that sulphanilamide is a potent but, in the doses necessary for therapeutic results, a somewhat dangerous remedy for gonorrhea.

Cases of gonorrhea treated as bed patients under careful medical supervision require large doses of sulphanilamide given at frequent intervals throughout the 24 hour day for several days in order to obtain satisfactory results. Apparently about 84 per cent of cases thus treated have been cured, but too few cases have been followed for adequate periods to permit definite statements as to the percentage of ultimate cures. Of acute cases, 76 per cent were apparently cured and of chronic cases, 97 per cent were apparently cured by sulphanilamide therapy. Results in outpatient services have thus far been less satisfactory. About 55 per cent of ambulatory patients were apparently cured on the basis of clinical and bacteriological findings, in a group studied at the New York City Department of Health.

The reasons for the substantially better results in bed treatment as compared with ambulatory treatment seem to include the following: (1) bed rest is beneficial in any treatment of acute gonorrhea; (2) the control of the intake of fluids is difficult in ambulatory patients; (3) the ambulatory patient may not take his medicine regularly and in the proper doses.

At the best, taking all cases as they come, some 15 or 20 per cent do not respond to treatment, but an analysis of cases indicates that chronic cases do much better with sulphanilamide than acute cases. This may be because sulphanilamide supplements and aids the body's own defense mechanism and

gives the best results if administered after the defense mechanism has already swung into action.

In order to obtain satisfactory results in the treatment of gonorrhea, large doses of sulphanilamide must be given. Mahoney, Van Slyke, and others¹² gave nearly 8 grams of sulphanilamide per day for several days and then reduced the dose, in any case giving the drug at 4 hourly intervals. Somewhat smaller doses are given to ambulatory patients. In both types of cases water is limited to 1 or 1½ liters per day. It has been observed that if improvement does not occur in the first 5 days of treatment, the chances of subsequent satisfactory results by this method are poor and the treatment with sulphanilamide may as well be discontinued.

Not only gonorrhea in the adult but vaginitis in little girls is apparently cured by sulphanilamide. The results of sulphanilamide treatment of gonococcal vaginitis are believed to be about the same as those obtained by the use of estrogenic substances. Gonococcal infections of the eye also appear to do well with sulphanilamide administered as systemic treatment in addition to the standard local treatment.

The therapeutic dose and the toxic dose of sulphanilamide are perilously near to each other. And the toxic manifestations of the drug are numerous and sometimes serious. Among the gravest is acute hemolytic anemia. Common manifestations of intoxication, one or more of which are observed in many thoroughly treated cases, include photosensitive eruptions resembling the measles rash, cyanosis, acidosis, dizziness, headaches, shortness of breath, diarrhea, general depression, and ringing in the ears.

Some of these toxic manifestations can safely be ignored, others can be successfully combated by the physician, but some demand instant withdrawal

of the drug. The precautions which should be taken in order to attain the full therapeutic effect of sulphanilamide and at the same time avoid serious complications include, in addition to daily clinical supervision, frequent estimation of the concentration of sulphanilamide in the blood, hemoglobin estimation, and cell count including a differential count of the white cells. Thus sulphanilamide can only be administered safely by a physician with the assistance of a competent laboratory, preferably with the patient in a hospital.

Recently, the press of the whole country has carried stories of deaths attributed to the administration of a preparation called "Elixir of Sulphanilamide." At this writing 69 deaths have been traced to this preparation. It is believed that not the sulphanilamide itself but an adjuvant called "diethylene glycol" which was used in this mixture was responsible for these fatalities, but this experience emphasizes the great danger that may accompany the use or prescription of untried and unapproved preparations. The Board of Health of New York City has forbidden the sale of sulphanilamide except on the prescription of a licensed physician.

While nothing in the long and gloomy history of gonorrhea has aroused hope of its eventual conquest like the discovery of sulphanilamide in its treatment, there are, let us not forget, many difficulties. Sulphanilamide sometimes causes symptoms to disappear while the patient still remains infectious with gonococci in the prostatic and other secretions. Haphazard, unscientific treatment methods will doubtless lead to many still infectious cases being turned loose to spread the disease, just as in the past. Again, we are faced with the difficulty that though best results are obtained by bed treatment, beds are, in fact, available for only a small fraction of existing cases. These do

not seem to be insuperable obstacles. Better trained, more conscientious physicians can overcome the first difficulty, and education and a reasonable hope of success can lead taxpayers to provide the necessary beds. Also the comprehensive experimental work now in progress may develop better methods for ambulatory treatment.

Where, then, do we stand today with regard to gonorrhea? We have three new methods of treatment of gonococcus infections. Each of these forms of treatment apparently gives quicker and better results in the type of cases to which they are adapted. Patients seem to be more speedily cured and made non-infectious. Once we have perfected these newer methods, our problem would seem to be to make these newer, more effective means of treatment generally available so that gonorrhea may be cured and rendered non-infectious *speedily*. We can then attack gonorrhea along lines quite similar to syphilis and tuberculosis; namely, find the cases and render them non-infectious by treatment. When this can be done promptly in a large proportion of cases brought under medical supervision, it will be necessary to mobilize public health resources for an active medical attack on gonorrhea.

Meantime we should not forget that to avoid infection with any disease is better than to be cured of it; and that our educational, preventive program should be pushed even more vigorously than before.

I cannot conclude this paper without referring to medical and administrative research problems now being studied in the New York City Department of Health. In the purely medical field, we are studying the biology of the gonococcus and the effects of drugs in experimental animals, Dr. Alfred Cohn having discovered in a brilliant piece of work a method of infecting mice.¹³ Cohn has also improved the methods of stain-

ing the gonococcus for microscopic examinations and has developed a more satisfactory culture method. Our administrative studies in Staten Island are testing epidemiologic and case-holding procedures; and we are serving Staten Island physicians by offering them the Kline finger blood test for routine application in their offices. Also on the administrative side, the enactment of new and more satisfactory laws requiring pre-marital and prenatal examinations has brought a large additional number of individuals under medical supervision.

On the whole, one may conclude that advances during the last 3 years have carried us a long way in the right direction. Further progress on all aspects of syphilis and gonorrhea control can be expected as one of the results of the recent federal appropriations for this purpose.

Results of Contact Investigation in Syphilis in an Urban Community*

T. B. TURNER, M.D., A. GELPERIN, M.D., AND
J. R. ENRIGHT, M.D.

International Health Division, Rockefeller Foundation, and School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.; Department of Health, Cincinnati, Ohio; and Bureau of Communicable Diseases, Board of Health, Honolulu, T. H.

ONE of the principal objectives of programs directed toward the control of syphilis is to bring about a reduction in the attack rate of the disease. With the control methods now available this can be best accomplished by decreasing the average period of infectivity, through early anti-syphilitic treatment of persons newly acquiring syphilis. Establishment of easily accessible, well managed syphilis clinics may encourage infected persons to seek treatment earlier than they otherwise would, but a serious obstacle to complete success of this method is offered by the fact that many infected persons are completely unaware of the presence of syphilitic lesions during a period in which these lesions are most highly infective. This is particularly true with regard to females. Moreover, infectious cases of syphilis occur principally among youths and young adults and among the least well informed members of the

community. It is of the utmost importance, therefore, that the syphilis control program should include adequate facilities for seeking out persons who are potential sources of infection in order that they may be brought under medical care and rendered non-infectious as promptly as possible.

The most practical method of discovering potential sources of infection is contact investigation, which may be defined as the attempt to identify and bring under medical observation persons who have been in intimate contact with an individual known to have syphilis. Although contact investigation has become an established part of the syphilis control program in the United States, few data are available on the actual results, in terms of new cases of syphilis discovered, that are likely to be achieved. It is evident that incalculable personal values, both on the part of the patient and of the medical personnel, may play an important rôle in determining the results in a given clinic or community. Nevertheless, it seems desirable to analyze the results obtained in various types of communities with a view to establishing an average level of accomplishment for

* From the Syphilis Division of the Department of Medicine and the Department of Public Health Administration of The Johns Hopkins University, Baltimore. Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 23, 1938.

this phase of the control program. As one step in this direction there will be presented the results of contact investigation in a series of 247 patients with infectious syphilis admitted to the Syphilis Clinic of The Johns Hopkins Hospital.

From the work of Munson,¹ Smith and Brumfield,² L. B. Ingraham,³ N. R. Ingraham,⁴ Kimbrough, Cowgill, and Bowerman,⁵ and Clark and Sargent,⁶ as well as from the accumulated experience of workers in many syphilis clinics, the practicability of contact investigation has been established. It is difficult, however, to obtain from these papers, with a few exceptions, an estimate of the number of new syphilis cases brought under treatment in relation to the number of original cases studied. It is true that useful data are available on the number of contacts examined, and on various methods employed in bringing these individuals under medical care; but the most reliable measure which can be widely applied would seem to be a ratio based on the number of all previously unrecognized cases of syphilis among contacts to the number of original cases comprising the study.

N. R. Ingraham,⁴ reporting the results of contact investigation from two clinics in New Jersey, found that in one clinic, investigation on 70 cases of early syphilis resulted in the discovery of 25 additional cases of syphilis, which is a ratio of 36 contact to 100 original cases. In the other clinic contact investigation on 65 patients with early syphilis yielded 15 new cases of syphilis, which is a ratio of 23 contact to 100 original cases. Clark and Sargent⁶ in a series of 431 original or initial cases of early syphilis succeeded in locating and examining 275 persons who were named as contacts. Among this number, however, there were only 52 cases of syphilis which were previously unrecognized and untreated.

Of these, 45 were among individuals with presumably infectious syphilis. Thus in this series the result of contact investigation in terms of previously unknown cases of syphilis was approximately 12 contact for each 100 original cases.

SOURCE OF MATERIAL AND METHOD OF STUDY

The material on which this paper is based comprises 247 patients with primary and secondary syphilis admitted consecutively to the Syphilis Clinic of The Johns Hopkins Hospital between September 1, 1936, and June 30, 1938. These patients will be designated "original cases." Only patients who applied voluntarily for admission and who had received no treatment prior to admission are included in the study. Patients with primary and secondary syphilis are designated "infectious cases" on the assumption that they were potential sources of infection in the community. For comparative purposes the results among a group comprising 87 colored patients between the ages 14 and 24 years, inclusive, with latent syphilis will be presented. With few exceptions all the original patients resided within the limits of Baltimore City.

Contact investigation was carried out in the following manner: The clinic physician in charge of the original patient attempted to obtain the names and addresses of persons who might have infected the patient or to whom the patient might have transmitted the disease. Included as contacts were only persons who had been in direct and intimate physical relationship with the original patient, such as by sexual intercourse, by kissing, or by sleeping in the same bed. In most instances exposure was through sexual intercourse. The patient was then referred to the clinic social worker who attempted to secure additional data on sexual and house-

hold contacts. If the contact named was living in the home as a marital partner of the patient, whether or not the couple were legally married, the contact was designated as a "marital contact." If the contact was not living in the home with the patient, the individual was termed a "non-familial" contact. A few persons, not marital contacts, who had been in intimate contact with a patient within the home, were also examined. These have been designated "household contacts."

The information regarding contacts obtained from patients proved to be of varying grades of usefulness. In many instances names and addresses, later proved accurate, were obtained. Contacts were frequently located when either or both the name and address were incomplete. In contrast to these, however, patients frequently referred to individuals as their contacts but gave identifying data so incomplete that no further investigation was possible. For the purpose of this study a contact was considered "named" if sufficient data were available to enable the social worker to start a search for the individual. Contacts residing outside Baltimore City or its suburbs are not included in the study, although efforts were made through the state health department concerned to have such contacts examined. It should be emphasized that perhaps the most important part of contact investigation is carried out in the clinic. Time and patience devoted to obtaining accurate and complete information from the original patient will save many home visits and much time in bringing the patients' contacts under observation.

The patient was asked to give each contact named a printed card requesting the contact to report promptly to this or some other clinic or to his family physician for examination. If the patient refused to do this or if a check of these agencies within a few

days revealed that the contact had not reported, the social worker made a visit to the contact's home or place of employment in order to urge him or her to report. If one visit was not successful, frequently others were made. The contact was approached tactfully without the name of the original patient being used, and it was rare that the efforts of the social worker were resented by the person named as contact or by the patient naming the contact.

Contacts upon whom information with regard to syphilis was obtained have been divided into four groups, as follows: (1) infectious cases, (2) latent cases, (3) syphilis known previously, (4) non-syphilitic. The group of infectious cases comprises those with primary or secondary syphilis. The group of latent cases comprises persons in whom a diagnosis of syphilis was made on the basis of a positive serologic test of the blood but who presented no manifest lesions of the disease. This group also includes a few persons found upon examination to have syphilis but in whom no details regarding the stage of the disease were available. The group designated "syphilis known previously" comprises persons named as contacts who were found to be already under treatment for syphilis or to have been treated at some previous time. As a rule, information on these persons was obtained from health department or clinic records. The non-syphilitic group comprises those persons found not to have syphilis. As a rule the last observation on these persons was several months after the original patient had been rendered non-infectious by treatment.

When a contact brought into this clinic was found to have infectious syphilis an effort was made, in turn, to identify and examine his own contacts. These infected contacts were not counted as original cases. Among the contacts of contacts were only a small

number with syphilis (11 in all), and these have been included in the analysis of the main group of contacts.

One practical difficulty encountered in contact investigation was that concerned with determining the probable period of infectivity in the original case. This was particularly true with regard to female patients. Often, it could not be determined accurately whether a contact named had been exposed to the original patient during or before the period of infectivity. No attempt has been made, therefore, to divide the contacts with regard to whether exposure was antecedent or subsequent to infection of the original patient. Since we are here interested principally in the number of new cases of syphilis brought to light through contact investigation, the number of contacts named or examined, or the time of exposure to the original case is of secondary importance. We wish to stress the end results in terms of

sources of infection, rather than the mechanism of arriving at this result.

RESULTS OF CONTACT INVESTIGATION AMONG INFECTIOUS CASES

The distribution of original cases by race and sex, the number of these patients naming contacts, and the total number of contacts named are shown in Table I. Likewise shown are the distribution of the contacts according to the relationship to the original case and the number of contacts examined, together with their distribution according to diagnostic classification. For each race and sex are shown the ratio of infectious cases discovered, and of all cases of syphilis newly discovered, to original cases. These ratios may be used as an index to the actual results achieved by contact investigation.

For the entire group of 247 original cases there were 322 contacts named. Of these, information regarding syphilis was obtained on 237, which is in the

TABLE I

Result of Contact Investigation in a Series of 247 Patients with Primary or Secondary Syphilis

Data on Original Cases				Data on Contacts							Ratio		
Race and Sex	Number	Number Naming Contacts	Number of Contacts Named	Type of Contact and Number	Diagnostic Classification					Total New Cases	Number of Infectious Contact Cases to 100 Original Cases	Number of Infectious and Latent Contact Cases to 100 Original Cases	
					Number Examined	Infectious Syphilis	Latent Syphilis	Syphilis Known Previously	Non-syphilitic				
White Male	37	23	29	{ Marital 16 Non-Familial 13	15	9	2	0	4	19	41	51	
White Female	17	13	22	{ Marital 8 Non-Familial 13 Household 1	4	1	1	3	4	5	18	30	
Colored Male	85	56	104	{ Marital 20 Non-Familial 84	15	5	5	2	3	36	25	42	
Colored Female	108	86	167	{ Marital 35 Non-Familial 126 Household 6	29	11	8	7	3	54	32	50	
Total	247	178	322		237	74	40	60	63	114	30	46	

ratio of approximately one contact to each original case. Of the 237 contacts on whom information was obtained as the result of contact investigation, 74 were found to have primary or secondary syphilis, which gives a ratio of 30 infectious contact cases to each 100 original cases. In addition 40 other contacts were for the first time discovered to have syphilis, without manifest lesions. Contact investigation, therefore, was responsible, in part at least, for bringing under medical care 114 previously unknown cases of syphilis, approximately two-thirds of which were potentially infectious. The ratio of previously unknown cases of syphilis among contacts was 46 contact cases to 100 original cases.

It is of considerable interest that, of the contacts located, 60 or approximately one-fourth were found already to be under treatment for syphilis or had been under treatment previously. Obviously, these cases cannot be credited to the results of contact investigation. Rather, they form a group in which contact investigation was inadequately carried out by some other treating agency.

Approximately one-fourth of the contacts examined proved to be non-syphilitic after adequate periods of observation, despite the fact that they were named as contacts of patients with known infectious syphilis. It is not known whether these persons represent instances in which exposure occurred only prior to onset of the disease in the original patient, or whether other factors affecting communicability were operative. Suffice it to say that the information obtained from the original patient did not permit of an accurate prediction regarding the result of examination in the contact.

There was no pronounced difference in the results of contact investigation obtained among whites and negroes or

in the two sexes of each race. The results appear to be poorer for the group of white females than for the other groups, but the numbers are small and the differences are not statistically significant. Indeed, any of the differences noted could well have been due to chance alone.

TIME ELAPSING BETWEEN ADMISSION OF ORIGINAL CASE AND EXAMINATION OF CONTACTS

The value of contact investigation will probably be in direct proportion to the length of time by which the infectious period is shortened in those contacts who have syphilis. It is exceedingly difficult to obtain precise data on this point, but the available evidence suggests that many infected contacts were brought under medical observation sooner than if they had been left to apply voluntarily for medical care.

Among white contacts, excluding those already under treatment, 56 per cent of those found to be syphilitic came under medical observation within 1 week of the date of admission of the original case, and 78 per cent within 4 weeks. The apparent cause and effect relationship is too strongly evident here to be ignored, particularly in view of the fact that many infected contacts were unaware of the presence of lesions. Among colored contacts 33 per cent of those found to be syphilitic, and not already under treatment, came under observation within 1 week, and 50 per cent within 4 weeks. Of interest is the fact that among both white and colored contacts those eventually proved to be non-syphilitic did not report as promptly, on the average, as did those with syphilis.

Another finding, which strongly suggests that the period of infectivity was materially shortened in some infected contacts, is the fact that in 2 male contacts and 5 female contacts the first

clinical or serologic evidence of syphilis developed after the individual came under medical observation. Moreover, in 13 male and 10 female contacts the disease was in the primary stage when the individual came under the care of a physician. In this series of infectious contact cases, then, 45 per cent of the males and 42 per cent of the females came under medical care before or during the primary stage of the disease. Of approximately 6,000 infectious cases, including contact cases, admitted to the Syphilis Clinic of the Johns Hopkins Hospital between 1918 and 1936, 34.1 per cent of the males and 9.6 per cent of the females were in the primary stage of syphilis. It would seem, therefore, that females in particular were reaching the clinic earlier because of contact investigation.

CORRELATION OF VARIOUS SOCIAL FACTORS WITH THE RESULTS OF CONTACT INVESTIGATION

In the foregoing section the results of contact investigation have been computed in terms of the number of original cases in the series. In this section some of the social factors which may affect these results will be discussed. In general the percentages will be based on the number on whom information was obtained, but it must be noted that such figures have significance only when related back to the number of original cases.

A slightly higher proportion of female original patients named one or more contacts than did the males of either race (79 per cent and 65 per cent, respectively). White patients named a proportionately smaller number of contacts than did colored patients, but of the contacts named there was no significant difference in the proportion of each race that was examined (80 per cent of the white contacts and 72 per cent of the colored). Of the contacts

upon whom information was obtained a smaller proportion of white contacts were known previously to have had syphilis than was the case among colored contacts (14.5 per cent and 20 per cent, respectively), but the proportion of non-syphilitic contacts was about the same in each group.

A larger proportion of the white original cases named marital partners than did the colored original cases (44.5 per cent and 28.5 per cent, respectively). Of the marital contacts named a somewhat lower proportion of the colored was examined as compared with the white (70 per cent and 80 per cent, respectively), but the differences are not statistically significant. A lower proportion of non-syphilitic individuals was found among the entire group of marital contacts examined than among the group of non-familial contacts (11.1 per cent and 30.5 per cent, respectively).

RESULTS OF METHODS UTILIZED IN CONTACT INVESTIGATION

In the series of patients under study the approach to the contact was through a card or letter transmitted by the original patient, through a letter posted to the contact, or through a visit by the clinic social worker or nurse. Since in individual instances there was some overlapping of these methods, an accurate appraisal of the results of each cannot be made, but the following observations may be noted.

Among white contacts 83 per cent of the marital and 44 per cent of the non-familial contacts reported as the result of a contact card alone. Among colored contacts, 60 per cent of the marital and only 12 per cent of the non-familial contacts reported as a result of a contact card. One or more home visits were made to 44 per cent of the white non-familial contacts and

to 81 per cent of the colored non-familial contacts. Possibly had not home visits been made promptly, usually within 2 weeks of admission of the original case, a larger proportion of contacts would have reported solely through the efforts of the original patient, but no definite data are available on this point.

The method of employing a letter by post to the contact has not been used extensively because of the general impression among the clinic personnel that it is not an effective method in this community. In rural areas it may be much more useful and may greatly reduce the number of visits required of the social worker or public health nurse.

NUMBER OF HOME VISITS MADE

For all of the 262 contacts named and not already known to another agency 258 home visits were made, or slightly less than one visit per contact named. Of the entire group of contacts, 177 were examined and 258 visits were made, giving a ratio of 1.5 visits per contact examined. Since 74 infectious contacts were brought under medical care, this gives a ratio of 3.5 visits per infectious case discovered. The ratio of visits to the total number of syphilis cases discovered is 2.2 visits per case.

RESULTS OF CONTACT INVESTIGATION AMONG LATENT CASES

For comparative purposes the results of contact investigation among a group comprising colored persons with latent syphilis between the ages 14 and 24 years, inclusive, have been analyzed. These cases represent consecutive admissions to the Syphilis Clinic of The Johns Hopkins Hospital during the period covered by the study. (There were too few white patients of similar ages to include in the analysis.) Of 87 original cases 60 named 83 contacts, and of the contacts named 46, or 55 per cent, were examined. Among this number 3 cases of infectious syphilis and 11 cases of latent syphilis were discovered; 13 contacts were already known to have syphilis and 19 were found to be non-syphilitic. The ratio of contacts with infectious syphilis to original latent cases is approximately 3:100 and of all contacts with previously unrecognized syphilis 16:100. A comparison of the results among latent colored syphilitics with those among white and colored infectious original cases is shown in Table II. The results of contact investigation among this group of young latent syphilitics is not strictly comparable to the results among the group of original infectious cases, for undoubtedly a greater amount

TABLE II

Comparison of Results of Contact Investigation on Groups of White and Colored Original Patients with Infectious Syphilis and Young Colored Patients with Latent Syphilis

Original Cases			Contacts			
			Infectious Cases		All Previously Unrecognized Cases of Syphilis	
Type	Race	Number	Number	Ratio to 100 Original Cases	Number	Ratio to 100 Original Cases
Infectious	White	54	18	33	24	44
Infectious	Colored	193	56	29	90	47
Latent	Colored	87	3	3	14	16

of energy and enthusiasm was put into investigation of the contacts of the latter group. Nevertheless, the results suggest conclusions which are in accord with the prevailing opinion among syphilologists, namely, that not many sources of infection in the community will be discovered through contact investigation of latent syphilitics. Further studies, however, should be made on this question.

COST OF CONTACT INVESTIGATION

Only a rough approximation to the cost of contact investigation can be made in this series of infectious and latent original cases. Since this is a teaching clinic, postgraduate students have assisted in all phases of the work. Moreover, other duties such as the follow-up of patients delinquent from treatment and social service case work have been intermingled with those related more directly to contact investigation. However, a large part of the burden of contact investigation has been carried by one social worker, and it is conservatively estimated that fully half of this worker's time has been devoted to that work alone.

Computed on an annual salary of \$1,500 for the 22 months covered by the study, the cost of this service was \$1,375. This represents a minimum figure and does not include the cost of transportation, telephone, or postage. Altogether 128 previously unrecognized cases of syphilis were brought under treatment, 114 as contacts of infectious cases and 14 as contacts of latent cases. This figure divided into \$1,375, the cost of the social worker's services, gives the cost per case as approximately \$10. Computed on the same basis, the cost per infectious case brought under treatment was about \$18 (\$1,375 divided by 77).

Whether these figures are high or low in comparison to the cost in other

clinics or health districts is not known, for no other estimates based on the cost per new case brought under treatment are available. In one large urban clinic³ the cost per contact examined was estimated to be \$5.22, but no data are available from that study on the number of contacts found to have syphilis. Perhaps the figures given for our clinic are unduly high due to the fact that this clinic serves also as a teaching center. It would be interesting to have cost estimates derived from clinics devoted more exclusively to the treatment of large numbers of persons with syphilis.

DISCUSSION

One of the important aspects of the syphilis control program is that concerned with the measurements of results achieved by various methods employed in different phases of the program. It is suggested that the results of contact investigation should be estimated in terms of new cases of syphilis brought under treatment in relationship to the number of original cases in the series. Proportions or ratios based on other figures may not be free from sources of error because the number of persons naming contacts and the number of contacts named may vary greatly in different clinics, according to different criteria for designating a contact as "named." For example, personal data available for identifying a contact vary so much that it is often difficult to decide when a contact has been named. Again, it is often exceedingly difficult to estimate the period of infectivity in an original case, hence assigning a person as a contact during the period of probable infectivity of the original case is often a matter of individual judgment. The basic figures used in this study, number of original cases, and number of previously unrecognized cases of syphilis among the

contacts, are easily ascertainable and are not subject to errors of selection.

While the immediate results of contact investigation can readily be measured, it is not possible yet to determine the ultimate results to the community as a whole. Evidence is at hand which indicates that from 1932 to 1937 there was little or no change in the number of new syphilis cases occurring in the Eastern Health District of Baltimore City, from which area many of the individuals in the present study were drawn, despite the fact that good treatment facilities were available during this period. Perhaps energetic contact investigation may help to change this trend. During the past 2 years at least 77 persons who were potential sources of infection in this community were rendered non-infectious fairly promptly after an effort was made to bring them under treatment. It would appear that the average period of infectivity was shortened in this group of cases and there are sound reasons, based on epidemiological principles, for believing that some new cases of the disease were thereby prevented. Whether the results were worth the estimated cost of contact investigation must be at present largely a matter of opinion; it is our opinion that the results achieved in this series of patients were well worth the cost.

SUMMARY

1. In a series of 247 original patients with primary or secondary syphilis contact, investigation is credited with bringing under treatment 114 previously unrecognized cases of syphilis. This is a ratio of 46 contact cases to 100 original cases.
2. Of the contacts examined 74 had primary

or secondary syphilis and were obviously potential sources of infection in the community. The ratio of infectious contact cases to original cases is 30:100.

3. Of the total contacts on whom information was obtained approximately one-fourth were already under treatment for syphilis by some agency at the time the original case was admitted to this clinic. Likewise, approximately one-fourth of the contacts examined proved not to have syphilis.

4. There was no significant difference in the results of contact investigation between white and colored patients or between male and female. Of the contacts examined, 11.1 per cent of the marital contacts were non-syphilitic compared with 30.5 per cent of the non-familial contacts.

5. In a series of 87 original cases comprising young colored adults with latent syphilis, contact investigation yielded 3 previously unrecognized infectious cases and 11 other cases of syphilis.

6. An estimate of the cost of contact investigation in this series shows that each previously unrecognized case of syphilis brought under medical care cost approximately \$10, and each infectious case cost about \$18.

ACKNOWLEDGMENT

The authors wish to express their appreciation to Mrs. Mildred Hughes who did most of the social service work on the patients included in this study.

Mean Annual Hours of Sunshine and the Incidence of Dental Caries*

BION R. EAST, D.D.S.

East Orange, N. J.

A SURVEY made under the direction of the U. S. Public Health Service covering dental examinations of over 1,500,000 children has been published.¹† It seems worth while to evaluate such extensive data in relation to other factors than those indicated in the *Bulletin*. The data available on seasonable incidence of dental caries^{2, 3} suggest the interesting problem of ascertaining whether or not a correlation can be established between caries incidence and hours of sunshine available per annum. The U. S. Weather Bureau data on hours of sunshine serve as a reliable source of information on the latter variable.⁴‡

The present report covers only a small portion of the projected plan, namely, the 12-14 year age group of the white boys residing in rural and semirural areas of the United States. In the original *Bulletin* the greatest emphasis was placed on city populations. For the present study, we have

chosen the non-city groups (population groups below 5,000), which in many respects are probably more homogeneous than the population of towns and cities with their more variable ethnological groups and more diverse habits of living. There are 94,337 boys of 482 communities of 24 states in this group.

From the original data, the caries incidence per 100 children was determined by totalling the numbers of fillings in the temporary and permanent teeth, the numbers of cavities in the temporary and permanent teeth, and the numbers of extracted teeth, as reported by Mills.⁵ The number of individuals in all 482 community groups was then arranged in a frequency table having class-intervals of 50 cavities per 100 boys (Table I, Column A).

From the grouped data, the arithmetic mean, the standard deviation, and the mean's probable error were determined.* The mean, 353.50 cavities per 100 boys, is many times greater than its probable error, ± 0.295 ; therefore, we can safely assume that the mean value is representative of the hypothetical universe from which the sample is drawn, and that any error

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

† Included in this study are additional but unpublished data from the same survey, used with the courtesy and permission of the Surgeon General.

‡ The methods of collecting these sunshine rates are described in the Weather Bureau *Bulletin* 802, U. S. Department of Agriculture, "Instruction for Care and Management of Electrical Sunshine Records," Circ. G., Instrument Division, Fifth Edition, by C. F. Marvin.

* Details of statistical calculations will be furnished those interested. The unpublished data used with the consent of the Surgeon General will also be supplied by the author.

introduced by chance or accidental sampling is negligible.^{6, 7, 8}

From the official weather map furnished by the U. S. Weather Bureau "the mean annual amounts of sunshine, in hours" for various sections of the United States were determined. The observations from which this map is made are recorded at some 90 meteorological stations. For this study, these sunshine values are arranged into four divisions: (a) those areas having more than 3,000 hours; (b) those having

2,999 to 2,600; (c) 2,599 to 2,200; and (d) less than 2,200 hours of sunshine per year respectively.

Frequency distributions of caries rates were made according to the mean annual sunshine value in hours for the community in which the children resided (Table I, Columns B, C, D, and E).

The arithmetic mean and the standard deviation with their probable errors were determined for each group. The means are 290.50 ± 1.79 cavities per

100 boys for the group living in localities having more than 3,000 hours per annum; 323.00 ± 0.36 , 375.65 ± 0.42 and 485.75 ± 2.04 in the B, C, D, and E groups respectively. In each case, the relations between the successive means and their probable errors is so great as to make it safe to assume that the mean values are representative of the respective hypothetical universes from which the samples are taken. The locations of the areas having the various mean annual amounts of sunshine in hours, are shown in Figure I. The mean caries incidence for those areas is graphically expressed in Figure II.

The probable errors of the differences between these various means have been determined. The difference between the means of the B and C groups is 32.50 ± 1.83 ; of the C and D groups 52.65 ± 0.56 ; and the D and E groups 110.10 ± 2.08 .

The lowest value is that between the B and C groups, but there the difference between the means exceeds the probable error of that difference 17.7 times.*

DISCUSSION

Jessen has written, "The conception that the weather exerts an influence on health of mankind is as old as the treatment of illness itself" (translation).⁹ Emerson has reported the influence of sunshine on growth of children and has noted that the incidence of acute infectious disease is lowest during the season having the greatest amount of sunshine.¹⁰ The relation of the seasons and dental caries incidence has been reported by McBeath and Zucker² and Erpf.³ In both investigations marked decrease in caries incidence was found in the months of greatest sunshine,

* The chances are less than 1,000,000,000 to 1 that the observed difference between any two of the means is due to chance distribution. See: Sherman, Henry C. *Chemistry of Food & Nutrition*, Appendix D, Macmillan, 1937.

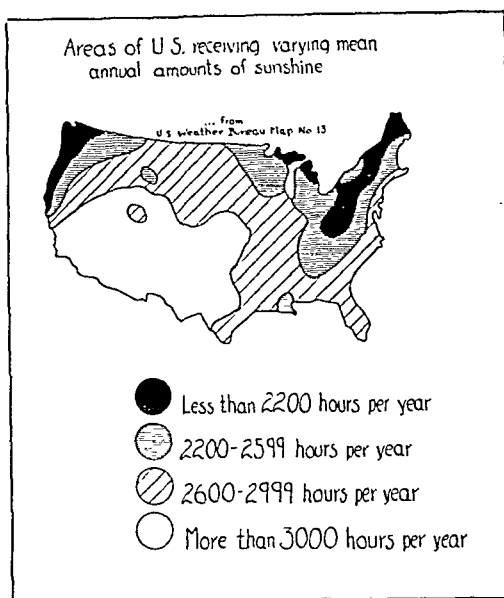

FIGURE I

when compared with those months having less sunshine.

Examinations of Indian children by members of the U. S. Public Health Service¹¹ seem to establish that those resident where the sun shines the greatest number of hours per year have

FIGURE II

a coincidental decrease in caries incidence over those living in areas of less sunshine. Moore and associates¹² found that 5 year old children of San Diego, Calif., having 3,000 hours of sunshine per year, had only one-half as much dental decay as children of the same age of Portland, Ore., with only 2,000 hours per annum.

The statement of Bunting¹³ that sunshine has no correlation with dental decay is at variance with the results obtained in this statistical study of 94,337 children living in various sunshine areas.

SUMMARY

1. The mean caries incidence of 94,337 white boys, 12 to 14 years of age residing in rural and semi-rural areas of 24 states during 1934-1935, was 353.50 per 100 boys.

2. The mean caries incidence of these boys varies inversely with the hours of sunshine prevailing at their places of residence. The group residing in the area having over 3,000 hours of sunshine per year had 290.50 cavities per 100 boys; the 2,600-2,999 hour group, 323.00; the 2,200-2,599 group 375.65; and the group with less

than 2,200 hours 485.75 cavities per 100.

3. The data presented suggest an inverse relationship (not necessarily causal) between the caries-attack rate among samples of white boys 12 to 14 years of age, and the mean annual number of hours of sunshine recorded for the places of residence of these children.

Epidemiology of Epidemic Encephalitis in California*

HARLIN L. WYNNS, M.D., C.P.H., AND
CARL J. HAWLEY, M.D.

Chief, Bureau of Epidemiology, California State Department of Public Health; and Medical Officer, California State Department of Public Health, San Francisco, Calif.

EARLY in the summer of 1937 increases in the incidence of poliomyelitis and encephalitis were noted in the San Joaquin Valley area of California. While the number of cases was not great, many were severe and the mortality rate was high. It was assumed at first that we were having an unusually high incidence of the encephalitic form of poliomyelitis, but as time went on it became evident that we were dealing with a disease entirely distinct from poliomyelitis which from the clinical standpoint corresponded closely to the outbreak experienced in St. Louis in 1933.

The medical profession was unaware of the presence of the St. Louis virus in the state—consequently the true nature of the early cases was not suspected. These were often diagnosed as poliomyelitis, polioencephalitis, epidemic encephalitis, epidemic meningitis, aseptic meningitis, lymphocytic or choriomeningitis, depending upon the predominating symptoms. For this reason the exact number of cases was difficult to ascertain as some of the

above diseases are not reportable in California. Tuberculous meningitis was also frequently considered, especially during the early part of the illness. Undoubtedly many of the earlier cases escaped our attention entirely.

The unusually high fatality rate, together with the high incidence of cases manifesting pronounced lethargy, focused our attention on them. Inasmuch as no outbreaks of encephalitis suggestive of the St. Louis type had been recognized in California previously, it was believed that the information accumulated in this outbreak would be of value, even though the epidemic could hardly be considered as of major proportions.

A comparison with past years' experience in poliomyelitis and epidemic encephalitis, Table I, shows a definite increase in the prevalence of the latter in 1937, the number of cases for that year being double the usual expectance.

Clinically, these encephalitis cases were similar to those described by Hempelmann in the 1933 epidemic at St. Louis.¹ They were characterized by profound prostration, sudden onset with high fever, severe headache, backache, chills or chilly sensations, nausea, vomiting, and convulsions were encoun-

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

tered frequently in children. Mental confusion, apathy, tremors, especially of the tongue and hands, and difficulty in speaking were often noted early in the disease.

The most constant single symptom was fever. This was unusually high, much higher than seen in the typical case of poliomyelitis. Temperatures of 105° and 106° F. were common, even in adults. Sixteen cases showed fever in excess of 106°F., and all but one of these resulted fatally. The exceptionally high fever and profound prostration presented an obvious and striking contrast to the usual case of poliomyelitis. Upon entering the room of these patients the contrast was noticeable. Also, none exhibited the apprehension and dislike at being disturbed so often observed in poliomyelitis with pronounced hyperesthesia. The case of average severity ran a high fever for from 5 to 7 days and dropped by lysis—the usual case returning to normal in from 10 to 15 days.

TABLE I
Epidemic Encephalitis and Acute Anterior Poliomyelitis in California*

	<i>Encephalitis</i>		<i>Poliomyelitis</i>	
	<i>Cases</i>	<i>Deaths</i>	<i>Cases</i>	<i>Deaths</i>
1930	82	57	1,903	157
1931	56	40	293	48
1932	57	38	191	31
1933	44	31	170	14
1934	45	22	3,399	110
1935	66	23	831	67
1936	67	34	388	38
1937	122	51	664	78

* All forms

Headache was a rather constant symptom and usually severe. There was no definite localization characteristic of the disease. Lumbar puncture with removal of fluid usually produced prompt relief of the headache for several hours.

Nausea and vomiting were present at the onset almost invariably in the younger age groups. In very young children convulsions were often noted.

Tremors of the hands, tongue, and lips occurred, especially when the patient was disturbed, was trying to concentrate on questions or attempting to make purposeful movements.

Mental confusion, disorientation, apathy, listlessness, drowsiness, semi-coma, and lethargy occurred in some degree in practically all cases; at least 75 per cent having a very definite lethargy. As a rule lethargy developed within a day or two after onset, becoming deepest at about the 5th to 7th day, gradually decreasing until the patient became practically normal in 10 to 14 days, although some patients continued to have sluggish mental reactions and apathy longer. Often the lethargy was profound and the patient could be aroused only with difficulty. Many of the fatal cases developed a condition undistinguishable from coma out of which they could not be aroused. The lethargy was such that the patient could be aroused and answer questions only to drop off immediately or while making the effort. A few showed no lethargy whatever; on the contrary, these had stages of mild excitement and delirium.

Nuchal pains and neck stiffness were common symptoms. Many complained of pain in the lower back. The neck rigidity was pronounced, a few (13 per cent) even having definite opisthotonos. Thirty per cent had positive Kernigs. The pronounced meningeal symptoms exhibited by some of these patients, combined with rather high cell counts, justified the provisional diagnosis of epidemic meningitis, made so frequently.

There seemed to be nothing uniform about the reflexes. Even in the same individual these varied from day to day. Absence of the abdominal reflexes was common. More often than not the tendon reflexes were exaggerated, sometimes markedly. The plantar reflexes, Gordon, Babinski, and Oppenheim, were quite variable.

Ocular manifestations were rare in contrast to the ordinary forms of encephalitis. Occasionally the patient complained of double vision and blurring. Strabismus and nystagmus were rarely observed. In a few instances reaction to light was sluggish.

Retention or incontinence of urine or feces was observed. Hyperesthesias were very uncommon; few patients exhibited any distress in manipulation of extremities other than in those instances when such manipulation incited tremors and spasticity.

Fifty per cent showed some degree of paralysis, mostly of a spastic nature. Often the patient had a lead-pipe rigidity of the extremities with greatly exaggerated reflexes. Difficulty in swallowing and loss of speech were noted. In most patients, the paralysis was temporary and cleared up with clinical recovery, although a few had a spasticity of all extremities lasting for several weeks, and in 2 this persisted for months. Most of those patients showing absence of reflexes and flaccidity of muscle groups died and these symptoms were noted shortly before death. Some of the recovered cases, however, had a temporary flaccid paralysis involving one or more muscle groups.

While there was considerable variation in the spinal fluid findings, as a rule the fluid was under slightly or moderately increased pressure, usually clear, but occasionally ground glass or slightly cloudy in appearance, with the cell count ranging from normal limits to 1,000 or more. The average count was from 200 to 400 cells with lymphocytes predominating, even up to 100 per cent. Sugar was not reduced and globulin was usually within normal limits or slightly increased. The spinal puncture was followed almost invariably by considerable relief, with less headache and more comfortable rest.

Some patients had extremely virulent

infections resulting in deaths within 4 to 6 days. In this series of 102 cases, 40, or 39.2 per cent, were fatal. This corresponds with a fatality rate of 37 per cent for the Paris, Ill., outbreak in 1932,² 20 per cent in St. Louis, in 1933, and 28 per cent³ in Toledo in 1934. Seventy-five per cent of all our deaths occurred before the 10th day, and 50 per cent before the 7th day. Those surviving over 12 days had a very good chance for recovery.

Epidemiologically, the disease was most interesting, especially from the standpoint of geographical distribution. The cases occurred in the San Joaquin Valley, an agricultural area with extensive irrigation, containing a number of small cities but no large metropolitan areas. Even in this area the cases were distinctly in rural sections. No cases occurred in the mountainous regions; and large population centers, such as San Francisco and Los Angeles, were singularly free from the disease.

The two counties reporting the largest number of cases were Fresno and Tulare, with populations of 150,304 and 84,432, respectively. Table II shows the geographical distribution of the 102 cases. Thus, Los Angeles County with a population of 2,691,707 reported 5

TABLE II
Geographical Distribution of Cases of Epidemic Encephalitis—St. Louis Type and Acute Anterior Poliomyelitis—1937

County	Epidemic Encephalitis	Poliomyelitis
Tulare	29	17
Fresno	28	9
San Joaquin	8	19
Los Angeles	5	245
Santa Clara	5	6
Sacramento	5	17
Kern	5	74
San Diego	4	57
Alameda	3	34
Yolo	3	3
Sonoma	2	5
Contra Costa	1	3
Santa Cruz	1	2
Madera	1	3
San Francisco	1	23
Colusa	1	3
	102	320

cases, while Tulare and Fresno Counties with a combined population of 234,736 reported 37 cases. In these two counties the cases were definitely rural in their distribution, often occurring in individuals living on ranches and in no contact with the public. San Francisco and Los Angeles accounted for only 5 per cent of the cases, although they hold approximately 50 per cent of the population of the state.

The seasonal distribution was similar to that in the outbreaks in the Middle West. The cases were most prevalent during the late summer and early fall—the same season that poliomyelitis was most prevalent. In Table III the distribution by months is shown together with that of poliomyelitis. Eighty-four per cent of the cases of encephalitis occurred during July, August, September, and October, while 80 per cent of the poliomyelitis cases occurred during this same period.

TABLE III

Cases of Epidemic Encephalitis—St. Louis Type and Acute Anterior Poliomyelitis by Months, 1937–1938

Month	Encephalitis		Poliomyelitis	
	Cases	Deaths	Cases	Deaths
1937				
March	1	1	10	1
April	1	..	15	3
May	1	1	22	2
June	3	3	40	6
July	13	7	134	7
August	40	11	157	28
September	22	5	132	12
October	11	4	84	6
November	7	6	36	8
December	2	1	12	5
1938				
January	9	2
February	1	1	11	1

There were more cases in the younger age groups of this series than were reported in the epidemic in the Middle West, although it is understood that in 1937 an increase in the incidence among the younger age groups in the Middle West was also noted. As indicated in Table IV, 38.2 per cent of the cases occurred in those under 14 years of

age, and this group accounted for 35.0 per cent of the deaths. The highest death rates occurred in the age groups 1–4 and over 55 years, each of such group having a fatality rate of approximately 62 per cent. It is realized that the number of cases involved in this series is too small upon which to base definite conclusions. The exceptionally high fatality rate is undoubtedly due to the fact that mild cases were unrecognized.

TABLE IV

Cases of Epidemic Encephalitis—St. Louis Type By Age Groups

Age	Cases	Deaths	Per cent Fatal	Per cent of Total Deaths
0–1	3
1–4	13	8	61.5	20.0
5–9	13	3	23.0	7.5
10–14	10	3	30.0	7.5
15–19	14	5	35.7	12.5
20–24	11	4	36.3	10.0
25–34	12	4	33.3	10.0
35–44	9	5	55.5	12.5
45–54	8	3	37.5	7.5
55+	8	5	62.5	12.5
	102	40	39.2	100.0

The sex distribution shows nothing significant—58 males, 44 females. Multiple cases in families were rare. In only one family did more than one case occur; there were 3 cases, 2 of which were mild, and all 3 came down within a period of 6 days. Other than this one instance no case could definitely be traced to contact with a recognized or suspected case.

At postmortems the pathological findings were limited chiefly to the brain and cord. In all autopsied cases the brain showed evidence of edema, congestion of the meningeal and intracerebral vessels, small petechial hemorrhages into the cortex and into the meshes of the pia-arachnoid. In many instances, the brain was quite soft and flabby due to the excessive fluid. The microscopic picture was that of an acute non-purulent inflammation throughout the brain and cord, especially in the pons, medulla, and mid-brain, petechial

hemorrhages and intense vascular congestion with cellular infiltration of both nervous tissue and meninges with various types of mononuclear cells, chiefly lymphocytes, and evidences of toxic degeneration of the nerve cells. These findings correspond to those previously reported for the St. Louis virus.⁴

Unfortunately, brain material in condition suitable for virus studies was obtained in only a few instances, and in those, no virus could be demonstrated. The laboratory work was done by B. F. Howitt,⁵ of the George Williams Hooper Foundation, University of California Medical School. In 41 of the cases, virus neutralization studies were carried out by Miss Howitt,⁵ using the viruses of lymphocytic choriomeningitis and the St. Louis type of encephalitis.

In 21 cases the virus of the St. Louis type was neutralized while in no instance was the other virus affected. Inasmuch as blood for the most part was obtained only from the milder and recovered cases, it would seem fortunate that so many positive results were obtained. In one instance blood taken a few hours before death neutralized the virus. As a rule, the blood was collected during convalescence.

That the disease was present in California before 1937 is evident. The sera from two individuals who were not ill in 1937 were found to neutralize the virus. One gave a history of an abortive attack of poliomyelitis in 1935, the other an abortive attack in 1936. Both lived in the same county and had not been out of the state. As reported,⁶ these individuals may have suffered attacks of encephalitis rather than poliomyelitis, or they may have at some time or other been exposed to the virus and developed sub-clinical infections.

An attempt was made to follow up these patients and determine the extent of after-effects. In spite of the marked toxicity and the severity of the illness,

those recovering seemed to have few sequelae. Recovery occurred in 62 cases and 14, or 22.5 per cent, of these showed some disability not present before onset. However, follow-up studies were carried on within less than 6 months after onset and is entirely too short an interval upon which to base conclusions. The most frequent complaint (noted in 6 cases) was weakness, with inability to do as vigorous work as formerly. Four individuals complained of neuritic pains in muscles of the arms and legs. Two complained of frequent and severe headaches. One, a child, had definite impairment of memory; another had signs of internal hydrocephalus. Two showed some muscular incoördination, ataxia and spastic paralysis of one arm, present a year after onset. So far, none has shown any tendency to develop Parkinsonism, although the period is as yet too short to which to draw a conclusion. Bredeck, *et al.*,⁷ in a follow-up study on the St. Louis outbreak, report that Parkinsonism was found to be quite uncommon as a residual.

Cases occurring during 1938 are being followed with a great deal of interest. As would be expected the cases are more widely distributed throughout the state, appear to be milder, and the fatality rate is correspondingly low.

CONCLUSIONS

1. This represents the first recognized outbreak of epidemic encephalitis due to the St. Louis type of virus in California.

2. In all, 102 cases were recognized from March, 1937, to February, 1938. There were 40 deaths.

3. Blood was obtained from 41, usually during the stage of convalescence. Twenty-one of these neutralized the St. Louis type of virus.

4. Geographically, the disease was limited to the rural areas of the San Joaquin Valley section of California, while the metropolitan areas were relatively free.

5. A definitely greater incidence of the disease in the younger age groups was noted

than occurred in the St. Louis outbreak of 1933.

6. Three to 6 months after recovery—22.5 per cent of the patients showed some disability which could be attributed directly to the disease. These ranged from headaches and weakness to spastic paralysis and mental changes.

NOTE: While this paper is based principally on cases occurring in 1937, it is felt advisable to mention briefly events during 1938. To date (October 15, 1938) 66 cases of epidemic encephalitis have come to our attention. The geographical distribution has been similar to that recorded last year.

In a number of these cases positive neutralization tests have been obtained with the St. Louis virus. However, some have been negative although the clinical picture was suggestive of the disease, as was noted also last year. Since this paper was written Miss Howitt⁸ reports the isolation of the virus of equine encephalomyelitis, Western type, in a fatal case from Fresno County. This case in a child, age 20 months, had a fulminating illness lasting 5 days, characterized by high fever, convulsions, spasticity, opisthotonus, and hyperactive reflexes. The spinal fluid count ranged from 12 cells per cm. to 44 cells per cm., with about 50 per cent lymphocytes. In Kern County, sera from 3 cases of encephalitis in children were found to neutralize the same virus.

Equine encephalomyelitis in horses has been present in California since 1930. In 1933 Meyer⁹ reported 3 cases in humans (1 fatal) which he felt were due to this virus. All had been in intimate contact with horses ill with the disease. Fothergill, *et al.*,¹⁰ recently reported the isolation of the virus of the

Eastern type of equine encephalomyelitis from a fatal case, in a child, age 7 years, who lived in an area in which the disease was present in horses.

Most of the cases reported in this paper resided in areas where equine encephalomyelitis in horses has been present. It is considered a possibility therefore that some of the cases which have been negative for the St. Louis virus, also some of those who neutralized the virus, may have been due to the equine strain. With that in mind sera are now being obtained from many of these persons for neutralization tests with the virus of equine encephalomyelitis.

Educational Qualifications of Health Officers*

A Report for the Consideration of the Governing Council at the 68th Annual Meeting, Pittsburgh, October 17-20, 1939

THE type of training most desirable for an individual seeking to become a health officer is well recognized. He should have had fundamental training in the sciences and the humanities at least equivalent to that required for a college degree in Arts or Science. He should have completed the course leading to the degree of Doctor of Medicine in a recognized medical school, and should have had at least 1 year of internship in an approved general hospital, including a communicable disease service. In addition to such internship the candidate should be given a preliminary period of supervised field experience in a well organized department of health for a period sufficient to give him acquaintance with the general aspects of public health and to give him also opportunity to determine something of his own liking for the work and his fitness for it. At the end of this preliminary field experience the candidate should receive at least 1 full academic year of graduate instruction in public health in a university. If possible, the candidate should have an additional year of practical experience in a subordinate position before be-

coming himself responsible for the conduct of the work of a department of health.

However desirable so complete a course may be, it is impracticable at this time to insist that all candidates for appointment comply with these requirements. In view of this practical situation, some modification may temporarily be made in the direction of recognizing the value of practical field experience obtained under competent supervision as in some measure substituting for formal education.

A few exceptional individuals not possessing a medical degree have achieved outstanding success as administrative health officers. It is reasonable, therefore, that the basic training represented by the medical degree, although advisable, should not be considered absolutely essential in the selection of health officers for jurisdictions where the duties of the health officer are mainly administrative, provided the candidate possesses an adequate general and biological education and has received not less than 2 academic years of graduate instruction in public health in a university.

RECOMMENDATIONS

1. That candidates for appointment as health officer should be graduates of approved medical schools who have completed successfully not less than 1 year of internship in an approved hospital and in addition a course of not less than 1 year of graduate instruction in

* The Committee on Professional Education of the American Public Health Association publishes this Report to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the Report. Approved by the Committee on Professional Education April 25, 1939.

a university, leading to a degree in public health.*

2. That recognition be given to the fact that practical experience in public health administration is an essential part of the education of a health officer, and that great achievement can usually be attained only after long experience. These facts should always be taken into consideration in the selection of health officers, particularly where the position is one of great administrative responsibility.

The above recommendations are made for the future guidance of officials responsible for the appointment of health officers, and for the guidance of individuals looking forward to careers in public health. In making these recommendations the committee ex-

pressly recognizes the professional standing of persons now performing creditable service as health officers.

* Where lack of qualified personnel makes it impossible to require a full year of graduate instruction in public health, the postgraduate requirements considered temporarily as applicable for medical health officers for small jurisdictions may be: the satisfactory completion of not less than 3 months of postgraduate instruction in public health in a university and not less than 3 months of supervised field experience in a well organized health department. Such individuals should be required to complete the course leading to a graduate degree in public health as soon as they have demonstrated ability sufficient to warrant such instruction.

Desirable Qualifications of Nurses Appointed to Public Health Nursing Positions in Industry*

*A Report for the Consideration of the Governing Council at the 68th
Annual Meeting, Pittsburgh, October 17-20, 1939*

THESE qualifications are suggested as aids to schools of nursing and those arranging public health nursing curricula, in planning future training programs, and as goals for nurses who wish to prepare themselves for service in this important field.

At present the number of nurses who, through education and experience, can meet all of these qualifications is limited. The qualifications, however, may serve as guides to employers in selecting nurses, and to encourage nurses already in service to secure further preparation.

Personal Qualifications:

The following personal qualifications are of the utmost importance for the nurse in industry:

An interest in and ability to work with all kinds of people; good physical health and emotional stability; initiative; good judgment; and resourcefulness. For the nurse working alone without nursing supervision, ability to organize her service also is necessary. The supervisor of other nurses must have qualities of leadership, executive and teaching ability, vision, and imagination.

(An idea of the nurse's personal qualifications may be obtained by personal interview and by reading her record from the nursing school and previous employer.)

Professional Qualifications:

I. For the nurse in an industry which provides supervision by a qualified nurse supervisor set forth under III below.

A. High school graduation or its educational equivalent is essential. More advanced education on a college level is desirable. Ability to use the typewriter and perform other clerical procedures is helpful to the nurse, especially in smaller industries where clerical assistance is limited.

B. Fundamental nursing education. The following are essential:

1. Graduation from an accredited school of nursing connected with a hospital having a daily average of 100 patients or a minimum of 50 patients with one or more affiliations affording supplementary preparation.

a. Instruction and experience in the care of men, women, and children, including patients with communicable disease.

b. Thorough instruction and

* The Committee on Professional Education of the American Health Association publishes this Report to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the Report.

Approved by the N.O.P.H.N. January 25, 1939, and by the Committee on Professional Education of the A.P.H.A. April 25, 1939.

experience in surgical nursing, including operating room and first aid.

2. Instruction and experience are desirable in the following:

- a. Outpatient department, especially in the emergency room.
- b. Psychiatric nursing.

C. State registration.

II. For the nurse in an industry working without the guidance of a nursing supervisor.

This nurse must be able to plan the nursing program under the general direction of the medical officer, and should have a working knowledge of the principles of teaching, social case work, community organization and resources, public health administration, industrial relations, personnel administration, industrial hazards, nutrition, communicable disease, mental hygiene, and personal hygiene, as they affect the individual and his family.

A. All of the preparation listed above under I, and in addition:

1. At least one year of experience under qualified nursing supervision in a public health nursing service in which practice in the application of the above can be secured.
2. An academic year of study in public health nursing in one of the colleges or universities whose program is approved by the N.O.P.H.N.
 - a. Where courses in industrial hygiene and safety are available.
 - b. Where courses in principles

of public health nursing, mental hygiene, social work, preventive medicine, and allied subjects are made applicable to nursing in industry.

c. Where field work includes some experience in industry.

3. Supplementary experience and instruction in operating room and first aid nursing, if thorough preparation was not included in basic nursing education.

III. Supervisory positions

All the preparation under I and II, and in addition:

Successful experience in industrial nursing, part of which is preferably in the type of industrial work in which she is to act as supervisor.

GUARDING THE HEALTH OF VISITORS TO THE GOLDEN GATE INTERNATIONAL EXPOSITION

SAN FRANCISCO is having an exposition this year just as New York is. San Francisco calls hers the Golden Gate International Exposition. The Department of Public Health has taken time by the forelock and in conjunction with the Water Department began a survey of the hotels on June 1, 1938, paying particular attention to the plumbing in order to insure a pure water supply to the tremendous number of guests who will undoubtedly visit the city. Especial attention was paid to cross-connections, which are always a danger, and have often allowed nonpotable water in other localities to reach the pure supply with disastrous consequences. The survey was completed by January 1, 1939. There were 651 hotels inspected and all hazardous conditions detected were corrected by January 15, or a month prior to the opening of the exposition on February 17.

In addition to the water supply, the condition of the sewers and the connections were also studied, as were also the fire system, water treatment equipment, and special house storage. Special attention was given to the water fixtures and connections in the kitchens and all departments devoted to the handling of food.

Except for very new hotels, blue prints of the piping are rarely available and those of the original building plans seldom resemble the layout actually found in old structures. Of the 651 hotels inspected, 82, or 12.6 per cent, were found to have one or more serious plumbing hazards, all of which, as pointed out, have been corrected. Advice and instruction were given to proprietors and they were also encouraged to look forward to remodeling and extension as opportunity offered, the gradual replacement plan being favored.

The method of routine bacteriological check of the general water supply of the city has been revised and improved and in addition to the tests of the general water supply, samples are examined once a week from all hotels which have dual supplies. It is felt that visitors can spend as much time in the city as they desire with a high degree of safety from diseases due to defective water supplies.

Treasure Island, the site of the Exposition, is under the Health Director

of the City and County of San Francisco. It is needless to add that every precaution has been taken to render the ground of the Exposition itself safe for visitors. All places supplying food or drink are under careful supervision which will be maintained throughout the time that the Exposition is open. The survey of the water supply, the correction of faults in plumbing, and the improvement in the bacteriological supervision of the water supply will be continued as a permanent benefit to the city under its efficient health system.

RESTORING LOST VITAMINS TO THE DIET

DESPITE the abundance and variety of American foodstuffs, the people of this country are, on the whole, not so well nourished as they should be. Most persons may consume food in sufficient *quantity*, but a surprisingly large proportion of the population apparently fails to select foods that give proper nutritive *quality*. Measured by the accepted standards of human nutrition, our national diet is defective, a fact that has a definite influence upon the state of the public health.

How do we know that the national diet is defective? By computing the actual national consumption of various foodstuffs, such as milk and dairy products, eggs, fruits, vegetables, bread and cereals, meats, and sugar, and comparing these figures with the amounts that would represent better all-round nutrition. Thus, we eat too much raw sugar and do not consume enough pasteurized milk, bread, eggs, fruits and green and yellow vegetables.

Recent investigations of approximately 4,000 food records among families in 43 cities have shown, furthermore, that fully half of these diets needed improvement.¹ Perhaps the most significant of the dietary faults discovered was a lack of sufficient calcium and vitamin A. Many of the diets were also inadequately provided with vitamin B₁ (thiamin), vitamin C (ascorbic acid), and iron. No data are given in this report on vitamin D, but many observations have indicated a paucity of this important food factor in the average family diet.

Assuming that these figures are fairly representative of conditions in the country as a whole, how can this situation be remedied? By improving economic conditions, and by the constant education of the public in the principles of sound nutrition. Public health education must include proper dietary information.

There is another way in which our national nutrition might be improved. If manufacturers and processors of various staple foods would develop methods to retain or restore the natural vitamins and minerals that are sometimes removed from these foods, their popularity and abundance in the diet would assure a greater intake of essential food factors.

Wheat and other grain products are outstanding examples. In the refining of flour, much of the original mineral and vitamin content is reduced. Some of these substances, but not all, are restored when white bread is made with milk solids, as is now the usual custom in the baking industry. White bread is our best and cheapest source of necessary food-energy, and there is no reason why it should not now be liberally used in a well balanced daily diet, but it would be even more valuable if it contained a larger quota of the vitamin B₁ (thiamin) and the iron of the unrefined wheat flour. The same can be said of milled white rice, another common cereal.

This problem of the restoration of lost vitamins to foods received considerable attention at the meeting of the American Institute of Nutrition in Toronto last

April. Various speakers advocated the fortification of our common foods with the vitamins and minerals in which they are often deficient.

Some progress has already been made in this direction. Fluid milk and evaporated milk have been fortified with vitamin D for a number of years, although these irradiated, metabolized, and concentrated vitamin D milks are used by only a relatively small proportion of the general public. Methods of milling white flour to retain vitamin B₁ have also been developed, and a yeast rich in this vitamin is now available for baking purposes, but these salutary methods have not yet been widely adopted. While vitamin A is now added to some of the margarines and other butter substitutes, this essential food factor might well be added to all of the fats that are lacking in it.

Optimal nutrition is one of the most important factors in good health. Modern food manufacturers have a glorious opportunity to contribute to national vitality by increasing the dietary values of their products.

PROLONGED PRESERVATION OF FOOD

WHEN we consider the important place which canned foods play in the life of civilized man today, and especially in the United States, it is rather surprising that more is not written concerning them. Scientific men and domestic science teachers know that the commercial canners have well equipped laboratories and employ the most expert scientific men and technicians. Also they take advantage of the services of many of the professors in our best universities; but in spite of all this the public generally and even professional persons, lack to an amazing degree a knowledge of the fundamentals of the great canning industry. Cases of poisoning, such as the deaths from botulism which occurred soon after the World War have attracted considerable attention. One still finds even among educated people superstitions concerning canned foods, the belief, for example, that as soon as air is admitted to a can the contents are liable to become dangerous and even poisonous. For example, in 1935, a national organization issued precautions against accidents in the home and advised the immediate removal of food from cans on opening. Again in 1936 a release by a national press service to newspapers throughout the country gave the impression at least that food left in open cans might become dangerous to health. Even authoritative bodies which should have known better have added to this erroneous idea.

In America there has recently become available an excellent book by A. W. Bitting,¹ than whom there is no one more capable of informing us on this great subject. The section on the history of the art of canning was written by Mrs. Bitting. The subject has been brought to the fore again in an excellent paper,² which has brought out valuable comment.³ This paper gives full credit to Nicholas Appert as having laid the foundation of the modern canning process in 1804. His book went through a number of editions in French as well as in English, and, in spite of the fact that in England Thomas Saddington was given an award by the Society of Arts, he admitted that his ideas were obtained while traveling abroad.

The article just referred to gives in some detail the process developed in England by John Hall of the Dartford Iron Works, and Bryan Donkin, a Fellow of the Royal Society, who substituted the use of iron containers for the glass jars first used by Appert. It must be remembered that Appert later used tin, a good quality of which at that time it was impossible to obtain since the French were poor artisans in working this metal, so that Appert made the cans in his own factory. Later he made his cans of wrought iron which he coated with tin after their manufacture. These contained from 4 to 45 pounds. The seams were brazed, and the cans were so strong that when emptied they were used as casseroles.

How long does a properly canned food remain good? As long as the can remains intact. We have been in the habit of quoting Letheby for the statement that in 1824 a ship with many tins of canned food was wrecked in Prince's Inlet. Eight years later Sir John Ross recovered some of these and although they had been exposed to alternate freezing and thawing they were in good condition. Sixteen years later another lot was found, and in 1868—44 years after the ship was wrecked—the remaining tins were opened by Letheby and found to be in perfect condition. In 1865, severe floods on the Genesee River in New York swept away a number of factories. Sixteen years later canned goods which had been buried in the mud since the flood were recovered and found to be in good condition.

The most recent evidence has been furnished by Professor Drummond and his co-authors. Two canisters of food prepared by the Donkin process, one a 4 pound can of roast veal, from the stores of H. M. S. *Hecla* on Parry's voyages to the Arctic in 1824 and again in 1826, had been put in the museum of the Royal United Services Institution. The second was a 2 pound tin of "carrots and gravy," which had been on the third Arctic voyage in 1824. In opening the cans great precautions were taken to collect the gas. When the can containing veal was opened the gas rushed out under high pressure, certainly more than 15 pounds to the square inch. Chemically this was found to be mostly hydrogen due to the action of the acid soup on the tin lining. The meat was in excellent condition, the odor most appetizing, and though the fat had been largely hydrolyzed, no trace of rancidity was present. The taste was good, though insipid, and for 10 days maintained the health and normal growth of young rats. Both flavin and vitamin D were found, but vitamin B was absent. Bacteriological examination showed three different types of aerobic spore-bearing bacilli, all of which grew at 55° C. There is no question that these organisms had retained their life in the spore form for more than 100 years, and were probably derived from the flour used to thicken the soup. The can of carrots and gravy was bacteriologically sterile, but showed a high pressure of gas, which also consisted mainly of hydrogen. There was not enough to carry out animal feeding tests for ascorbic acid, but carotene was found in a concentration little below that of fresh carrots. The metal containers were examined in the International Institute for Tin Research, then returned to their owners, where they remain as an exhibit at the Royal United Services Institution in Whitehall.

BOOKS AND REPORTS

The Anaerobic Bacteria and Their Activities in Nature and Disease: A Subject Bibliography—By *Elizabeth McCoy and L. S. McClung*. Berkeley: University of California Press, 1939. Vol. I, 295 pp., Vol. II, 602 pp. Price, \$10.00.

This is a monumental work which does not lend itself to the ordinary review. The authors state in the preface that it is the result of approximately 5 years of research, covering some 10,500 original articles in journals, monographs, or other published reports, with 120,000 entries. With a few exceptions, which are noted, each of these articles has been examined in the original and placed in the appropriate subject section. Even after this gigantic task, the authors do not claim that the index is "complete," as certain publications were not available to them.

Volume I is a Chronological Author Index and contains 295 pages. Volume II is a Subject Index and contains 602 pages. As an example of the arrangement, the Subject Index outline is divided into 9 heads, under each of which are subheads, running as high as 15 in some instances. In addition to the general subject matter there are special lists giving Bulletins of Institutes, Governments, etc., which report new data, Monographs, Obituaries, Patents, and Theses.

In the list of Species of Anaerobic Bacteria, there are some 425 spore bearing forms and 246 non-spore-bearing forms given. There are 98 named types of strains and 14 unnamed.

We commenced the notice of this book by calling it a monumental task, and so it is. It would be a bold re-

viewer who undertook to criticise without giving at least a year of study to it. We can only say here that it has every appearance of being a most carefully prepared piece of work and of being entirely authentic, of which the names of the authors would assure us. We cannot but admire the authors for their conception of the plan and their industry in carrying it out. Even putting it through the press must have been an enormous task.

We can understand the feeling of the authors when, in the last paragraph on page iv, they quote Dr. Heller: "The anaerobist working on bibliography is surely a creature to be pitied, and is not to be blamed for failing to follow the work of others conscientiously and thoroughly." MAZÛCK P. RAVENEL

Reorganization of the National Government: What Does It Involve?—By *Lewis Meriam and Lawrence F. Schmeckebier*. Washington: The Brookings Institution, 1939. 272 pp. Price, \$2.00.

While there is virtually nothing about public health in this book, persons who are interested in the possible coördination of some or all of the widely scattered health activities of our national government, and in the general promotion of efficiency and economy in the operations of the federal bureaucracy, will find much of interest and value in this book. The first part, by Mr. Miriam, discusses the philosophy behind the federal reorganization movement, and presents a lucid explanation of all the factors involved in it: while the second part by Mr. Schmeckebier describes the various attempts in the

past to do something about our unwieldy governmental machine. Both authors have devoted many years to research on the federal government and are experts in this field.

JAMES A. TOBEY

Civilization Against Cancer—By Clarence Cook Little, Sc.D. New York: Farrar & Rinehart, 1939. 150 pp. Price, \$1.50.

In furtherance of the laudable attempt to "fight cancer with knowledge," the managing director of the American Society for the Control of Cancer has prepared this compendium for the general reader. In 12 concise chapters he gives the rules for recognizing malignant growths, describes the history and present organization of the educational activities against cancer, outlines the progress of scientific research on the subject, and discusses various other pertinent aspects of this significant public health problem. Sanitarians will be particularly interested in the exposition of modern cancer research, a field in which the author has distinguished himself. Members of the Women's Field Army against Cancer will find that the book is an excellent guide for their worthy efforts, while other members of the lay public who have the courage to delve into the subject will derive much useful information and possibly some inspiration from this well printed book. JAMES A. TOBEY

The Municipal Year Book, 1939—Chicago: International City Managers' Association (1313 East 60 Street), 1939. 586 pp. Price, \$5.00.

This sixth issue of the *Municipal Year Book* devotes much more space to individual statistics of cities than previous issues. For the first time the *Year Book* presents an entirely new statistical section covering police, fire, utility, welfare, health, library, and recreation activities.

The *Year Book* is divided into six general divisions: résumé of municipal activities in each of 24 fields in 1938, general governmental data, municipal personnel, municipal finance, municipal activities, and sources of information. For each of the 1,809 municipalities in the United States over 5,000 population, the *Year Book* gives a great deal of information such as number, salary, term, and election date for city council, titles of officials elected by the people, utilities owned, etc. Another section of the book gives for each of 834 cities the number of employees, total salaries and wages, whether a city has a classification and pay plan for employees, and a list of cities in which municipal employees are unionized and to what unions they belong. For each of the 960 cities over 10,000 the *Year Book* lists the names of 12 chief municipal officials.

Two features which greatly increase the utility of this issue are an index to the contents of previous issues and a thumb index which gives immediate access to statistical tables. W. R. W.

Manual of Veterinary Bacteriology—By Raymond A. Kelser, D.V.M. (3rd ed.) Baltimore: Williams & Wilkins, 1938. 640 pp. Price, \$6.00.

The first edition of this book was published in June, 1927, the second in June, 1933. Since there are few textbooks on bacteriology written from this point of view, the former editions were received with much interest and appreciation by the veterinary profession and the medical profession as well, because of the intertransmissibility of many animal and human diseases.

In this third edition the author has improved the *Manual* very much by the inclusion of new material, and 88 pages have been added. The number of chapters has not been increased, but the old ones have been revised and brought up to date. The chapter on

Bacteriological Examination of Milk and Water is noticeable in this respect. This revision maintains the same high plane which characterized the former editions. It is a valuable addition to literature for veterinary students and those specializing in veterinary bacteriology.

The printing, make-up and illustrations are good. A. J. DURANT

Big Fleas Have Little Fleas, or Who's Who Among the Protozoa—By Robert Hegner. Baltimore: Williams & Wilkins, 1938. 285 pp. Price, \$3.00.

BIG FLEAS Have LITTLE FLEAS
Upon Their Backs to bite 'em
And LITTLE FLEAS Have LESSER FLEAS,
And so, AD INfinitum.

We wonder whether this presages a new type of textbook, a sort of intellectual painless dentistry, as it were! While the versicle which serves as the text for the author has been known for many years, no one has ventured to write a book in the same vein on such an abstruse subject as protozoölogy. The illustrations are plentiful and good. Alongside of correct representations in black and white, many beautifully done, we have caricatures which will not only fix the appearance of the organism, if not its name—*Acanthocheilonema* for example—in the mind, but will also impress upon the reader the many different types of these early forms of life and perhaps more so their various activities and modes of living, often at the expense of a human host. Most of these are extremely clever.

The author is one of the outstanding protozoölogists in this country and no one is better qualified than he to tell us about the protozoa. The scientific material is sound and most interestingly told. Interspersed throughout the text are a number of poems which prove that the author is as familiar with his

hymn book as with Pinafore. These are extremely amusing and all tell their story.

There are very interesting accounts of the author's trips into the jungles of the Philippines, where they hunted calingas and crocodiles for the sake of their protozoölogical contents, and in Tropical America where they hunted monkeys for the same purpose. These trips led to the production of a poem, the first two verses of which read:

In Filipino's tropic clime
Where everything entrances,
The monkey and the tarsier
Free wheel among the branches

In Panamanian wilds as well
The spider and the owl
Are monkeys full of parasites,
Ye Gods, just hear them howl.

The author points out things which we have to guard against in the future. For example, the International Highway is in the way of approaching completion and already we are in close touch with many tropical countries, so that motorists who stay there even a comparatively short time will be just about ready to exhibit symptoms of their catch when they reach home. Endemic areas will be established in certain localities in this country where intermediate hosts are indigenous. Even now the protozoölogist does not have to travel far to find an abundance of material, and apparently there will soon be a super-abundance. The author says plaintively:

"How did the protos become so prominent?
Mass reproduction rendered them dominant.
Why do the protozoölogists weep?
There're too many protos and too little sleep."

The book grew out of the Messenger Lectures, given before a general audience at Cornell University in 1937. There are three appendices, one General Remarks about Protozoa, one a Glossary—much needed by the average reader—and one Bibliography. A good index ends the scene.

The printing and make-up are excellent and the book can be recommended both for the information it contains and the delightful style in which it is written. Before this time one could hardly have imagined that such a difficult subject could be made so entertaining.

MAZÏCK P. RAVENEL

Virus Diseases and Viruses—

By Sir Patrick P. Laidlaw. New York: Macmillan, 1939. 51 pp. Price, \$.90.

This is an attractive and thoroughly satisfactory review of information concerning the filterable viruses. Conspicuously noteworthy is the discussion of the nature of these disease producing agents. While the various opinions currently expressed can scarcely be considered as having reached the stage of controversy they do remind one of the time when Bastian was opposing Tyndall, in England; especially do they recall the conciliatory remark of a British clergyman who, in seeking to pour oil on the troubled waters, said "It is now generally agreed that there is no such thing as spontaneous generation—excepting possibly with regard to the infinitely small." We have come dangerously near the conclusion that this statement should be made all over again. Therefore the section of this lecture which deals with the author's own theory is particularly timely.

So thoroughly interesting and so basically sound is this lecture that everyone concerned with disease should take the opportunity to read it carefully.

A. P. HITCHENS

The New Baby—By Evelyn S. Bell and Elizabeth Faragoh. Philadelphia: Lippincott, 1938. 64 pp. Price, \$1.00.

Photography with the help of simple captions tells the story of the arrival of the new baby and its place in the family. The book is designed to appeal to children who sooner or later raise

questions as to the origin of the new baby. The pictures are exceedingly well posed, in fact they appear as "candid shots," and occupy full pages opposite appropriate statements which carry the story from page to page. The book should prove valuable to parents and teachers as a medium to place in the hands of preschool children.

RICHARD A. BOLT

The Detroit Industrial Worker and His Health—Detroit, Mich.: Detroit Department of Health, Bureau of Industrial Hygiene, January, 1939. 30 pp.

Detroit's Health Department in this "photo off-set" brochure of 30 unnumbered pages makes a bid for community interest in industrial hygiene. A credo of 8 facets defines the wants of the industrial worker with respect to his health. In flowing style, easy for the "man on the street" to read and understand, the necessities for adequate industrial hygienic measures for the workers of Detroit are simply portrayed. The text is not unlike present-day popular magazine writing in the field of the medical sciences.

Outstanding difficulties and hazards confronting the workingman are described. Not too greatly burdened with statistics, with here and there an interesting line drawing and spot map, this publication presents a record of accomplishment and indicates the needs for the extension of future industrial hygiene activities in Detroit.

The introduction is an allegory in prospecting for "industrial health gold" in this manufacturing city. Short chapters on Detroit's factories and work places, Detroit's industrial workers, and high points in the bureau's activities for the year 1938 tell the general story. A chapter is devoted to silicosis, and a section under the title "One Achievement" relates the accomplishments of the automobile industry in

controlling lead poisoning. Basic terms in industrial health are defined, and, finally, the industrial health needs for Detroit's workers are outlined.

The report states "Detroit, already known to the world as a great industrial city, needs to be known as a city where the health of its industrial workers is adequately protected." This brochure is an excellent presentation and interpretation of the Bureau's work and plans.

BERNARD S. COLEMAN

Our Common Ailment: Constipation, Its Cause and Cure—*By Harold Aaron, M.D.* New York: Dodge Publishing Co., 1939. 192 pp. Price, \$1.50.

This is a very readable little book and contains a great deal of information on an ailment that some people may suffer from and a great many more think they suffer from. It is intended for the two classes just mentioned but can be profitably read by those who have no such ailment. It is written in non-technical language for the lay reader, but the information presented is based on the newer and scientifically tested knowledge of today. It deals with some of the worn out notions about the processes of digestion and the excretion of waste products. The author classifies and treats of constipation under three types; colonic, rectal, and spastic.

It tells about the false ideas great numbers of people have about the benefits of laxatives, colonic irrigations, and alkalinizations. It suggests the tremendous waste of money spent for these purposes and teaches that only in special cases should these measures be resorted to and only when recommended by a physician.

It classifies the many cathartics and laxatives in common use and points out that even when the use of such is indicated, some very cheap preparation

may be just as effective as the high priced article bearing a catchy name.

JAMES WALLACE

Medical Entomology, With special reference to the health and well-being of man and animals—*By William B. Herms.* (3rd ed.) New York: Macmillan, 1939. 582 pp. Price, \$5.00.

Though under a somewhat different title, this is the third edition of *Medical and Veterinary Entomology*, published first in November, 1915. This edition has been completely revised and reset and in almost every way has been brought up to date. Emphasis is placed on the rôle of insects and arachnids in public health and human welfare. All of the major groups of the arthropod vectors of disease are considered with their life history and recommendations made for their control. There is sufficient discussion on general parasitology and insect morphology to enable the reader to understand the part which arthropods play in the transmission of disease.

The last chapter in the book discusses the utilization of arthropods in medical practice. We find mention of some ideas which have been discarded, such as the use of cockroaches, crickets, and grasshoppers, one variety of which is said to have been a very good antidote against the poison of the scorpion. Of late years, owing largely to the influence of Baer, of Johns Hopkins, the employment of maggots in the treatment of wounds and indolent ulcers has gained a certain amount of popularity and the author gives directions for producing sterile maggots. Of greatest practical interest, however, is the use of the malarial parasite in general paresis, introduced in 1917 by Wagner-Jauregg. We could wish that this whole chapter were somewhat longer and went into more detail concerning the special laboratories in which mosquitoes are reared and in-

fects, then shipped considerable distances.

The author does not mention the fact that the *Anopheles gambiae* has reached the shores of South America, brought over probably from West Africa by an airplane or fast French destroyer. This is one of the most dangerous of all the malaria-bearing mosquitoes, and its presence in South America, especially in these days of the airplane, menaces the United States. It was recognized on this side of the Atlantic in 1930, and by 1931 had traveled up the coast from Natal 115 miles. In 1938 it was the cause of more than 50,000 cases of malaria in the Jaguaribe Valley. In the affected areas it is estimated that in 1939 nearly every person will be on government relief as a result of its ravages.

A few inaccuracies have been observed. Proper credit is given to Josiah Clark Nott as having been the first (in 1848) to advance a well formulated idea concerning the carriage of both malaria and yellow fever by mosquitoes, but he is credited to New Orleans. He was a native of Columbia, South Carolina, and a resident of Mobile, Alabama.

The printing and make-up are excellent. The illustrations are good, many of them especially so. It is dedicated to the late Dr. G. H. F. Nuttall, a native of California and the frontispiece is an excellent likeness of him. The book is a valuable reference text for practising physicians as well as teachers and students of medical entomology, and should be found in every medical library.

LEONARD D. HASEMAN

Veterinary Helminthology and Entomology—By H. O. Mönnig (2nd ed). Baltimore: Wood, 1938. 409 pp. Price, \$9.00.

The second edition, after 4 years, of this attractive textbook and reference work will be welcomed by persons con-

cerned with the health of man and of animals. The diction is clear and attractive in style. All sections are thoroughly systematized and there is a fine index. The bibliography is sufficiently extensive to indicate the main sources of information.

The first section deals with the general matters of parasitism, pathogenesis, pathogenic effects, resistance and immunity, general distribution and history; the second covers technic; this includes the collection and preservation of helminths and of arthropod parasites and the making of permanent preparations. There is a very practical section on clinical diagnostic methods in which the technical procedures in most common use are so described that they can be readily followed by laboratory technicians. There are short sections on blood examination for larvae and the technic for eliciting and studying allergic reactions. The section on helminth parasites gives adequate descriptions of the various parasitic worms; their arrangement and characterization are in accordance with the rules of the International Commission on Zoölogical Nomenclature.

The arthropod parasites are discussed after the same manner as are the helminths.

A useful appendix lists the parasites mentioned which infest man, equines, sheep, cows, cattle, pigs, dogs, cats, various wild animals, rodents, and birds.

The book is well printed on excellent paper and attractively bound. It can be thoroughly recommended as a working manual. A. P. HITCHENS

Proceedings, Occupational Disease Symposium—Chicago: Northwestern University Medical School, Department of Industrial Medicine, 1939. Paper covers, typewriter planograph, 99 pp. Price, \$3.00.

The report of this second annual

symposium, held September 26 and 27, 1938, comprises 8 papers followed by extensive discussions. In addition there are included 2 papers given at the Annual Dinner of the Department of Industrial Medicine, held November 15, 1938.

This second symposium contrasts with the first one held the year previous which was devoted chiefly to specific diseases among workers.

There is such a wealth of material embodied in the present symposium-report as to constitute a veritable textbook in itself. Unfortunately space does not permit even a brief synopsis. All of the authors and discussants are outstanding authorities in their various fields.

One feature, omitted from various conferences in this field, is upon formal industrial medical education, presented in detail by Dr. Peterson. He bases his paper chiefly upon inquiries made of medical and postgraduate schools and special societies, and shows serious oversight in this direction. Dr. Seeger of Milwaukee also stresses this as well as others of the discussants.

The reviewer feels that this symposium, like most of those in this field in recent years, fails to include the labor viewpoint as might be presented, for instance, by a physician actively connected with one of the labor unions, some of which are seriously promoting educational, recreational, clinical, and health projects. No doubt also a report from an officer of a sick benefit association would be interesting. There is also the point of view of the small business man and of the small plant, likewise that of the family practitioner in the mining, industrial, or agricultural labor area. The background effect of the economic status of workers upon their industrial health might be presented by a welfare or social case worker. Finally there is the desirability of a report by an intelligent but

impoverished worker who is confronted with the cost of family health maintenance and medical care in the face of a low average annual wage, such as \$975 as recently reported by the Social Security Board for the fairly good year of 1937, for over 30 million workers. The question is, Who really represents the worker in our numerous industrial health conferences, as valuable as they are as educational and inspirational forums?

The monograph contains several valuable tables, charts, summaries, and bibliographies, while the work has been carefully edited and the large type makes easy reading. An index would considerably enhance its utility.

EMERY R. HAYHURST

The School Health Program—
By C.-E. A. Winslow. New York: McGraw-Hill, 1938. 120 pp. Price, \$1.50.

An Inquiry into the character and cost of public education in the State of New York was undertaken late in 1935 in order to find out what the educational system of the state is accomplishing, how well its total program fits present-day needs, and what the costs of that program are and should be, with the purpose of reformulating the fundamental educational policies of the state. The Inquiry was divided into 3 major undertakings: (1) the examination of the educational enterprise in the state and the analysis of its outcomes, methods, and costs; (2) the critical appraisal of the work now under way; and (3) the formulation of policies and programs for dealing with the immediate problems and issues, and the long-range objectives of the educational system of the state. The purpose of the inquiry

... has not been to gather great masses of statistics, to devise numerous questionnaires, or to present meticulous factual descriptions of

every phase of education within the state. Rather, the Regents' Committee and the staff of the Inquiry have been interested in isolating major issues and in hammering away at the problems which presented themselves in order to find a reasonably comprehensive solution which would commend itself to the forward-minded people of the State of New York.

Among the studies separately published is a review of the health program of the schools by Professor C.-E. A. Winslow, assisted by Charles C. Wilson, M.D., Director of Physical Education, Hartford, Conn., and Martha W. MacDonald, M.D., of the Michael Reese Hospital, Chicago, Ill. Among those participating in the Inquiry were Don W. Gudakunst, M.D., of Michigan; Clara Bassett, Consultant in Psychiatric Social Work of the National Committee for Mental Hygiene, and Anne Whitney, Director of the School Health Education Service, Washington, D. C. The entire Inquiry was under the direction of Professor Luther Gulick of New York.

This report breaks down the school health program into sanitation in the schools, mental hygiene, health instruction, physical education and recreation, and health services. The report contains an excellent statement of the objectives of the health program broadly conceived, placing emphasis not only on a healthful physical environment but on a healthful intellectual and emotional environment interfused with sound and vital health instruction, a well planned program of physical education and recreation, and a health service program which includes a comprehensive health examination three times during the child's school life.

It is proposed that the health examination of the school child should be made wherever possible by the family physician and that it should be regarded as an educational procedure. The report recommends that the correction of defects should be primarily

a family responsibility, and that the chief function of the school nurse should be to arouse the sense of such responsibility. Where public clinic service is necessary it should preferably be provided by the health department or other community agencies rather than through the educational system. The board of education must, however, recognize the responsibility of providing necessary treatment where serious efforts to obtain it in other ways prove unavailing. The various elements of the school hygiene program should not be regarded as separate entities. They can be truly effective only when so integrated in a coordinated whole as to contribute to the sum of all experiences which favorably influence habits, attitudes, and knowledge relating to individual, community and racial health. For this reason the committee believes that all phases of the program should be under the jurisdiction of the educational authority, although medical and nursing personnel of the health department may often be used as the agent of the board of education in this field with great advantage.

The committee recommends the organization of a bureau of health education in the division of the State Education Department which controls the curriculum. This bureau, under the direction of a chief who is qualified as an experienced school administrator, should include representatives of health instruction, physical education, medicine, nursing, and dentistry. There should be added as well the specialists for the care of the physically handicapped. Two new fields should also be represented, namely, public health engineering and mental hygiene. An engineer to advise with regard to the health aspects of school construction and to carry on an educational campaign in the health aspects of school operation is regarded as essential. Similarly the appointment of a mental

hygienist is essential for the formulation and execution of any sound mental health program. This should be formulated in terms of the infusion of a mental hygiene point of view into the objectives and methods of education, rather than in terms of detecting cases of individual maladjustment. Mental hygiene is described as the essence of any true educational process. The report advises against the continuation in the bureau of health education of specialists in diseases of the eye and ear, and of the heart and lungs, partly because there are no corresponding experts in the local school systems for such

specialists to supervise and partly because their employment tends to stress an emphasis on curative problems which lie outside the field of education proper. It is recommended that the entire school health program should be formulated and conducted under the advice of a regularly constituted and continuing council on health education.

This report is both critical and illuminating. It will be of value not only in New York State but in other states where the experience of New York State as analyzed by so able a group of students can prove fruitful.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Interesting Statistic—Mr. Weller's excellent advice to his son Samuel to "be vware of vidders" finds statistical justification in this analysis. Well seasoned widows and divorcees for some reason, not stated, are able to catch men younger than can spinsters.

ANON. Age at Marriage and Remarriage. Stat. Bull. (Metropolitan Life Ins. Co.), 20, 4:4 (Apr.), 1939.

Proof That Prevention Pays—New England cities report downward trend in diphtheria deaths, the Middle Atlantic cities hold first place again, and throughout the rest of the country progress is reported in varying degrees except in the Pacific and Mountain states. Results suggest again that rates decline where health agencies urge prophylaxis.

ANON. Diphtheria Mortality in Large Cities of the United States in 1938. J.A.M.A. 112, 20:2043 (May 20), 1939.

Reassuring Vital Records—In 1938 deaths from typhoid and scarlet fever, diphtheria, polio, meningitis, tuberculosis, malaria, pellagra, nephritis, and diseases of pregnancy and childbirth were the lowest on record. Mortality rates from influenza and pneumonia were down too. Cancer and heart disease were the only major causes of death that were higher. Measles case incidence was up. Infant mortality reached a new low of 48, despite the increased birth rate which was up for the second consecutive year.

ANON. Trend of Morbidity and Mortality During 1938 and Recent Preceding Years. Pub. Health Rep. 54, 18:725 (May), 1939.

Typhoid Fever Deaths Reduced—In the large cities of the United

States, the trend of the typhoid fever mortality rate is still downward. Noteworthy gains were made in the North Central group of states and New England, and the Middle Atlantic states continue their excellent record of long standing.

ANON. Typhoid Fever in the Large Cities of the United States in 1938. J.A.M.A. 112, 19:1941 (May 13), 1939.

High Case Fatality Ratios—Two stimulating papers discussing the question of improved mortality experience among the tuberculous as an influence upon the general decline in tuberculosis mortality rates. One presents evidence that modern tuberculosis treatment does cure a large enough proportion of cases to have measurable effect upon rates; the other regretfully doubts the validity of the presented evidence.

BOGEN, E. Life Expectancy in Tuberculosis (and) DROLET, G. J. Case Fatality Rates in Tuberculosis. Am. Rev. Tuberc. 39, 5:587 (May), 1939.

Permanent Diphtheria Immunity—Quantitative Schick tests were done upon children earlier immunized with 3 doses of toxin-antitoxin, 2 doses of plain toxoid, 1 dose of alum-precipitated toxoid, or 3 doses of plain toxoid. The results suggest that more immunity is conferred when the antigen is given in greater number of doses at longer intervals. Three doses of toxoid at monthly intervals seem to give the best results.

BUNDESEN, H. N., *et al.* Diphtheria Immunity in Chicago. J.A.M.A. 112, 19:1919 (May 13), 1939.

Something New for Premies—A description of a sealed air-chamber incubator for premature infants which

removes most of the hazards of immediate contact and prevents air-borne infection while providing optimum atmospheric environment. Morbidity and mortality rates have been substantially lowered by its use.

CHAPPLE, C. C., and KENNEY, A. S. Limitation of Bacterial Contamination of Air by a New Automatic Incubator for Infants. *Am. J. Dis. Child.* 57, 5:1058 (May), 1939.

Who Gets Dental Care?—As you would expect, members of families in the \$5,000 plus income level have five times the dental services that those in the \$1,200 minus level enjoy. But this is only one of many important findings you will discover in this survey of the habits of a great many white families.

COLLINS, S. D. Frequency of Dental Services among 9,000 Families, Based on Nation-wide Periodic Canvasses 1928-1931. *Pub. Health Rep.* 54, 16:629 (Apr. 21), 1939.

Consoling Idea Scotched—Wishful thinking that cancer of exposed areas tends to curtail cancer of the more inaccessible parts finds no confirmation in this analysis of British mortality records. In general, occupations in which there is a relatively high skin and lip cancer rate also show an excess of cancer of other sites.

CONRAD, K. K., and HILL, A. B. Mortality from Cancer of the Skin in Relation to Mortality from Cancer of Other Sites. *Am. J. Cancer.* 36, 1:83 (May), 1939.

Maternal Care Does Benefit—Improvement in maternal mortality rates applies about equally to urban and rural residents. Although the environment may be better in rural areas, and complications of pregnancy more frequent among city dwellers, the more general availability of prenatal and postnatal care in larger communities compensates for the other factors.

DORN, H. F. Maternal Mortality in Rural and Urban Areas. *Pub. Health Rep.* 54, 17:684 (Apr. 28), 1939.

Unto the Least of These—Two million children are born each year, and 35 million more are still in the process of growing up. Here, indeed, is a social medical problem which is inevitably permanent. We have been slow to accept public responsibility in this regard, but we are showing signs of improvement.

ELIOT, M. M. Public Responsibility for Safeguarding the Health of Children. *Am. J. Dis. Child.* 57, 4:916 (Apr.), 1939.

Whooping Cough Prophylaxis—In a series of 4,212 children, 1,815 were immunized with pertussis vaccine and all were watched for 44 months: during this time 52 treated children contracted the disease and 348 of the controls also succumbed. Among the known exposed children the infection rate among the immunized was 12.8 per 100, compared with 68.5 in the controls. The attacks were less severe among the immunized children.

KENDRICK, P., *et al.* A Study in Active Immunization Against Pertussis. *Am. J. Hyg.* 29, 1:133 (May), 1939.

Eloquent Plea for Better Geriatrics—What we do not know about the mental habits, the emotions, and the capabilities of old people is convincingly set forth in this able review which concludes that there is no group of persons whose mental welfare is more neglected than the aged.

LAWTON, G. Mental Hygiene at Senescence. *Ment. Hyg.* 23, 2:257 (Apr.), 1939.

Colds, Effort, and Exposure—Whatever the causal agent of the common cold may be, it seems capable of precipitating onset most readily when it is present at a time when the normal defenses have been made vulnerable by fatigue-enforced increase in susceptibility to shock. For evidence, see paper.

LOCKE, A. Non-Specific Factors in Resistance. *J. Immunol.* 36, 5:365 (May), 1939.

Unsuspected Causes of Illness— Subclinical states of nutritive failure are of utmost importance to the hygienist because they are numerous and baffling, and because they impair the patient's sense of well-being. A number of such conditions are described and what was done about them is told.

McLESTER, J. S. Borderline States of Nutritive Failure. *J.A.M.A.* 112, 21:2110 (May 27), 1939.

Weather Controversy Continued—Prevailing average temperatures and man's combustion rates are related, this author maintains—despite the expressed doubts of others. That the northern half of the Mississippi enjoys more metabolic breakdowns than the southern part is a case in point. Diabetes, goiter, Addison's disease, as well as disturbances of the circulatory function are affected by this phenomenon.

MILLS, C. A. Climate Metabolic Stress. *Am. J. Hyg.* 29, 3:147 (May), 1939.

Why They Take Pen in Hand—Ten thousand requests for information addressed to the Public Health Service from every corner of the United States are surveyed. One hopeful sign is a shift from disease entities to hygiene, sanitation, and provisions for medical care in the questions asked. Also noteworthy is interest taken in chronic conditions rather than acute communicable diseases, which formerly received the lion's share of attention. Everyone will find this analysis most provocative.

OLESEN, R. What People Ask About Health. *Pub. Health Rep.* 54, 19:765 (May 12), 1939.

Tuberculosis Prophylaxis—This study indicates that vaccination with heat-killed tubercle bacilli confers some protection to the disease. The place was a Jamaica mental hospital where exposure is likely. About half of those admitted with negative skin tests were given 5 injections of vaccine. The

rest were controls. The attack rate was appreciably lower in the treated group.

OPIE, E. L., *et al.* Protective Inoculation against Human Tuberculosis with Heat-Killed Tubercle Bacilli. *Am. J. Hyg.* 29, 3:155 (May), 1939.

Civilized Tooth Decay—Dental caries is distinctly more prevalent among Eskimos who have picked up white man's habits than among primitive groups who have never enjoyed such blessings. The caries which does occur among the Eskimos is the common or garden variety.

ROSEBURY, T., and WAUGH, L. M. Dental Caries among Eskimos of the Kuskokwim Area of Alaska. *Am. J. Dis. Child.* 57, 4:871 (Apr.), 1939.

Certain Conclusions from Uncertain Data—Evidence in vital statistics is not of a quality to warrant a definite statement that heart-disease or cancer is, or is not, increasing as a public health problem. Discrepancies between recorded rates and reality vary widely in both degree and direction. Proof is given.

ROSS, M. A., and MCKINNON, N. E. Heart Disease and Cancer Trends. *Canad. Pub. Health J.* 30, 4:171 (Apr.), 1939.

About Leading the Horse to Water—Four years after being given contraceptive advice at a Cincinnati clinic, the recipients were interviewed. Four out of 5 seemed to be doing quite well, but more than half had rejected the advice they had received.

STIX, R. K. Birth Control in a Midwestern City. *Millbank Quart.* 17, 2:152 (Apr.), 1939.

Truth Where It Hurts—Garbage-fed hogs spread trichinosis. It may be saving pennies to feed raw garbage to swine rather than to dispose of it by more sanitary methods, but it is costly in terms of human health—so says this authority.

WRIGHT, W. H. The Whole Truth About Hog Feeding. *Munic. San.* 10, 5:268 (May), 1939.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Evon L. Anderson, M.D., Front Street, Fort Benton, Mont., Chouteau County Health Officer
- Irving J. Bridenstine, M.D., Terry, Mont., Prairie County Health Officer
- Thomas H. Bruce, M.D., C.P.H., Court St., New Cumberland, W. Va., Hancock County Health Officer
- Major Henry F. Buettner, M.D., 5005 Edmondson Ave., Baltimore, Md., Health Officer, City Health Dept.
- Hugh E. Dierker, Jr., M.D., 7300 Santa Fe Ave., Los Angeles, Calif., Consultant Communicable Disease Physician, Los Angeles County Health Dept.
- Tilman E. Dodd, M.D., C.P.H., Kaufman, Tex., Director, Public Health District 3
- William H. Hutto, M.D., 408 Armstrong-Landon Bldg., Kokomo, Ind., Health Officer
- Louis Salazar, M.D., Kanakanak, Alaska, Government Physician, Office of Indian Affairs
- Raymond A. Steadman, M.D., Health Dept., Wartburg, Tenn., Health Officer, Morgan-Scott District Health Dept.
- Kolbein K. Waering, M.D., C.P.H., 2547 St. John's Ave., Jacksonville, Fla., Director, Duval County Health Unit
- William R. Warren, M.D., 511 Eaton St., Key West, Fla., City Health Officer

Vital Statistics Section

- Percy W. Weston, Division of Vital Statistics, Parliament Buildings, Victoria, B. C., Canada, Assistant Inspector of Vital Statistics

Laboratory Section

- Elizabeth Cober, M.S., 1419 Elm Street, Wilkensburg, Pa., Technician in Bacteriology, Western Pennsylvania Hosp.
- Harry P. Gelsing, B.S., 100 Chaucer St., Helena, Mont., Chief Bacteriologist, Hygienic Laboratories, State Board of Health
- Philip B. Hadley, Ph.D., Western Pennsylvania Hospital, Pittsburgh, Pa., Chief, Bacteriological Service and Research Bacteriologist, Institute of Pathology
- Edward P. Joneschild, D.V.M., Livestock Sanitary Board, Helena, Mont., Deputy State Veterinarian
- Anita H. Leavitt, B.S., 422 West Main St., Lansing, Mich., Bacteriologist, American Public Health Assn.
- Gregory Pincus, D.Sc., Biological Laboratories, Clark University, Worcester, Mass.

- George W. Shadwick, Jr., B.S., 1526 South State St., Chicago, Ill., Director, Control Laboratory, Beatrice Creamery Company.

Public Health Engineering Section

- Leslie Cummins, Route 1, Huntsville, Ala., Sanitation Officer, Madison County Health Dept.
- Samuel M. Ellsworth, B.S., 12 Pearl St., Boston, Mass., Consulting Sanitary Engineer
- Charles F. Haynes, D.V.M., Lexington Apartments, Helena, Mont., Deputy State Veterinarian, Livestock Sanitary Board
- H. George Henderson-Watts, P. O. Box 1514, Kelowna, B. C., Canada, Chief Sanitary Officer, District Health Unit
- Otto J. Schmidt, B.S. in C.E., 307 South University, Peoria, Ill., Assistant Sanitary Engineer, State Dept. of Health
- William Shea, P. O. Box 332, 305-3 St., N. W., Great Falls, Mont., Sanitary Commissioner, City-County Health Dept.
- Benjamin Yuk Wo Wong, B.S. in C.E., Board of Health, Hilo, Hawaii, Sanitary Engineer

Industrial Hygiene Section

- Louis W. Spolyar, M.D., State House Annex, Indianapolis, Ind., Chief, Bureau of Industrial Hygiene, State Board of Health

Food and Nutrition Section

- Paul A. Downs, Ph.D., 1301 North 38 St., Lincoln, Nebr., Teacher and Research Worker in Dairy Bacteriology, University of Nebraska

Child Hygiene Section

- Abraham B. Rosenfield, M.D., Hibbing High School, Hibbing, Minn., School Physician
- Lewis A. Scheuer, M.D., 247 Wadsworth Ave., New York, N. Y., Pediatrician, New York Foundling Hospital

Public Health Education Section

- Fred F. Fitzgerald, Ph.D., 230 Park Avenue, New York, N. Y., Director of Research, American Can Company
- James G. Stubblebine, M.D., Big Timber, Mont., Sweet Grass County Health Officer
- Ralph O. Wagner, D.D.S., 2940 Summit St., Oakland, Calif.

Public Health Nursing Section

- Ruth Cassidy, R.N., 120 West 5 St., Red Lodge, Mont., School Nurse

Isabelle R. Durie, Weston, W.Va., Lewis County Public Health Nurse
 Agnes Fuller, R.N., 303 Ninth Avenue, New York, N. Y., Supervisor, Chelsea Bureau of Nursing, Dept. of Health
 Clara H. Gaddie, R.N., C.P.H., Yakutat, Alaska, Field Nurse, Office of Indian Affairs
 Ella B. Jones, C.P.H., P. O. Box 1114, Eustis, Fla., Public Health Nurse, Lake County Health Dept.
 Anne M. Leffingwell, M.S., B.N., Lane County Health Dept., Eugene, Ore., Supervising Nurse
 Helen J. McMillen, State Dept. of Health, Santa Fe, N. M., Regional Consultant, Public Health Nursing
 Monica Moore, R.N., Metropolitan Life Insurance Company, Hempstead, L. I., N. Y., Territorial Supervisor
 Katherine M. Prusak, Governor Hotel, Olympia, Wash., Field Nurse, Taholah Agency, U. S. Indian Service
 Lucille A. Schulte, B.S., 1020 Liberty Bank Bldg., Dallas, Tex., Director, Visiting Nurse Assn.
 Mildred E. Simantel, Board of Education, District 2, Billings, Mont., Public School Nurse

Epidemiology Section

Irving R. Abrams, M.D., 6754 Sheridan Road, Chicago, Ill., Assistant Epidemiologist, Board of Health
 John E. Elmendorf, Jr., M.D., Rockefeller Foundation, 49 West 49 St., New York, N. Y., Member, Field Staff, International Health Division

Elsie G. Schlosser, M.D., Byram Shore, Port Chester, N. Y., Research Worker, Columbia University
 Tennyson B. Sinclair, M.D., Medical Faculty, McGill University, Montreal, Que., Canada, Student

Unaffiliated

Nettie E. Alley, St. Helens, Ore., Columbia County Nurse
 Louis Block, Dr.P.H., 435 2nd Ave., New York, N. Y., Health Consultant, New York City Works Progress Administration
 Martha O. Elliott, Box 44, Arlington, Calif., Student
 Peter J. Galante, M.D., Klamath Agency, Ore., Agency Physician, U. S. Indian Service
 William S. Johnson, A.B., Jacksonville Tourist and Convention Bureau, Jacksonville, Fla.
 Horace M. Kawamura, 1606 Kilauea Ave., Hilo, Hawaii, Junior Sanitary Inspector, Territorial Board of Health
 Shintara Namihira, 8½ Miles, Olaa, Hawaii, Junior Sanitary Inspector, Territorial Board of Health

DECEASED MEMBERS

Maurice Brodie, M.D., Detroit, Mich., Elected Fellow 1934, Elected Member 1932
 Leo H. Flynn, M.D., Eau Claire, Wis., Elected Member 1930
 Charles H. Mayo, M.D., Mayo Clinic, Rochester, Minn., Elected Member 1928
 Walter S. Stanley, San Antonio, Tex., Elected Member 1937

CLOSING DATE FOR ACCEPTING FELLOWSHIP APPLICATIONS

NOTICE is hereby given to any interested members that September is the closing date for accepting Fellowship applications for 1939 election. Eligible members wishing to apply for Fellowship this year should submit their completed applications as much in advance of this date as possible.

AMERICAN PUBLIC HEALTH ASSOCIATION WORLD'S FAIR EXHIBIT

AN additional contributor to the exhibit on Public Health Administration which the Association is sponsoring at the New York World's Fair is Hugh B. Robins, M.D.

EDUCATIONAL QUALIFICATIONS REPORTS

THE Committee on Professional Education of the American Public Health Association has, during the past two years, presented five reports which have been approved by the Governing Council. They deal with the Educational Qualifications of Public Health Statisticians, School Health Educators, Public Health Engineers, Sanitarians and Sub-Professional Field Personnel in Sanitation.

These are available for free distribution in printed form, from the offices of the A.P.H.A., 50 West 50th Street, New York. The first two are issued separately and the other three are printed under one cover.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, when keyed, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y., identifying clearly the key number on the envelope.

POSITION AVAILABLE

Young woman bacteriologist to supervise industrial laboratory controlling paper manufacture and to conduct a factory hygiene program. Industrial experience desirable. **W419**

POSITIONS WANTED

HEALTH OFFICERS

Physician, M.D., class A medical school; M.S.P.H., University of Michigan, 1939; 10 years' experience in administrative full-time health programs; seeks public health administrative position. **A373**

Physician, aged 39; M.D. and Dr.P.H., Yale University; with excellent training in medicine, pediatrics and epidemiology; now specializing in public health education, will consider appointment in health education or administration. **A366**

Physician, M.D., Syracuse University; postgraduate studies in bacteriology and immunology, will consider position as health officer or epidemiologist. Has served as director of county health unit, director of industrial hygiene and medical statistics, and venereal disease field survey officer. **A305**

Physician, M.D., Yale; M.S. in field of public health, Columbia; also short course for health officers, Vanderbilt; good clinical background, 14 months' public health experience; will consider appointment in child health, epidemiology, or public health administration. **A350**

Experienced physician who has been local health officer and school physician in New York State, now has M.P.H. from Harvard School of Public Health, and wishes position in administration, epidemiology, or public medical service. **A423**

Physician, M.D., Columbia; experienced as county health officer and superintendent of health, seeks position in public health administration or medical executive work. **A396**

Physician, M.D., class A medical school; completed short course for health officers

at Vanderbilt; experienced health officer and director of county health unit, will consider appointment as health officer or school physician. **A320**

Well qualified physician, M.D., Rush; M.S.P.H., University of Michigan; with special interests in tuberculosis and venereal disease control, seeks responsible appointment. Excellent references. **A406**

Physician, M.D., class A medical school; 12 years' full-time public health experience; now employed with state department of health; will consider opening with well organized city or state department in communicable disease division or epidemiology or both. Mid-west preferred. **A409**

HEALTH EDUCATION

Well qualified woman in health education wishes position as health coordinator or health counselor. Has wide experience, and Ph.D. from New York University. **H236**

Young woman, M.A., Health Education, Teachers College, Columbia; with splendid international experience, seeks position as director of health education. **H369**

Young woman, Ph.D., Columbia University; splendid background of experience in health education, will consider position as director of public health education. **H294**

Woman, M.D., Boston University; special work Columbia and Massachusetts Institute of Technology; one year's experience in state hospital; interested in psychiatry, desires position in the East in hospital for mental diseases or industrial school. **H247**

Experienced teacher in public health and author; M.A., Columbia; now teaching public health nursing and carrying field promotion, wishes broader opportunity to train field personnel in extending health knowledge and interest to the general public, especially through group education, institutes, exhibits and rural programs. **H400**

LABORATORY

Capable research worker, Ph.D., trained at University of Southern California and Pasteur Institute, seeks position directing laboratory, in research work or field investigation. Has taught bacteriology, directed state hygiene laboratory and hospital laboratories. L315

Experienced laboratory director with background of dairy products manufacture and research in control methods; University of Wisconsin, M.S. and Ph.D., desires administrative position with food manufacturing or processing industry, or association with health department doing routine and research work in food control. L381

Chemist and bacteriologist, B.Sc.; M.S.P.H. from University of Michigan; experience in field work as chemist; serology training under Dr. Kahn at Ann Arbor, Mich. Three years' experience in public health laboratory work. Will consider position in public health field. L415

Young man, M.S.P.H., University of Michigan, knowledge of Medical Bac-

teriology and Public Health Sanitation, desires position in public or private health organization. L420

MISCELLANEOUS

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

State Director of Dental Hygiene, graduate, experienced dentist, now serving a state for the third year as director of dental hygiene, will consider change of position. M421

Physician, M.D., class A medical school; training in obstetrics and public health. Experienced as director of county health department, teacher of clinical obstetrics and administrator of state maternal and child health program, desires position in public health obstetrics or in maternal and child health administration. C417

Engineer with good training and experience in water treatment, sewage plant operation and in research, wishes position as superintendent. Can go anywhere. E422

Situations Open

PUBLIC HEALTH PHYSICIAN—Man especially experienced in maternal and infancy work, capable heading department in state board; east. 70-PH, Medical Bureau, Pittsfield Building, Chicago.

SCHOOL PHYSICIAN—Young physician, interested in working with children, with flare for public health; duties will include assisting city health officer, though public health training not required; \$2,400, car maintenance allowance; southern preferred; city of 75,000. 71-PH, Medical Bureau, Pittsfield Building, Chicago.

YOUNG PHYSICIAN—Training in public health work available under auspices state department of health for young man interested in this field; summer course; prospect for health appointment upon completion of course excellent. 73-PH, Medical Bureau, Pittsfield Building, Chicago.

DIRECTOR IN SYPHILOLOGY—Well qualified public health man with experience in large cities required; special training in syphilis work not needed; eastern metropolis. 72-PH, Medical Bureau, Pittsfield Building, Chicago.

STUDENT HEALTH PHYSICIAN—Preferably man interested in graduate work in public health; state university noted for splendid public health course; some teaching. 75-PH, Medical Bureau, Pittsfield Building, Chicago.

SCHOOL NURSE—Graduate nurse eligible to teach hygiene course prescribed by American Red Cross to high school students; minimum bachelor's degree required; some attention to general health problems of school and assisting with physical education; small, live city; central Illinois. 77-PH, Medical Bureau, Pittsfield Bldg., Chicago.

Situations Wanted

PUBLIC HEALTH NURSE—Teacher's certificate from state teachers college; graduate training in public health nursing, University of Minnesota; 6 years, public health nurse; 3 years, chief supervising nurse, division of child hygiene; for further information, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

HEALTH EDUCATOR—A.B., Wellesley; M.S. in public health from state university; 6 years, teaching physiology and science in public schools; 2 years, director of child health education, national organization; 2 years, health counselor and teacher of health education, midwest metropolis; 4 years' social work; for further details, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

BACTERIOLOGIST—Desires position, preferably in public health laboratories; B.A.; eastern school; C.P.H. and Ph.D. (bacteriology), Yale University; has done considerable research; 4 years, bacteriologist and research technician, public health laboratories; for further details, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH PHYSICIAN—A.B., midwestern college; M.D., Johns Hopkins; M.S.P.H., University of Michigan; interesting record of successful experience including long term as school physician in fashionable suburb; for further information please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

NEWS FROM THE FIELD

WILLIAM HALLOCK PARK RESEARCH FUND

WILLIAM Hallock Park, M.D., of New York, N. Y., who died in April, set aside in his residuary estate a fellowship fund for research in medicine, clinical work and for the study of bacteriology and filterable viruses.

This fund is to continue in perpetuity and is to be known as the "William Hallock Park Research Fund."

ROBERT LIVINGSTON SEAMAN FUND

THE New York Academy of Medicine has announced the establishment of the Robert Livingston Seaman Fund to further research in bacteriology and sanitary science. The Fund has been established through the terms of the will of Dr. Robert Livingston Seaman, and \$600 is available for assignment this year.

Applications from institutions or individuals will be received up to September 15.

CHINESE EDITION OF NATIONAL HEALTH SERIES

THE new edition of the National Health Series, published by the National Health Council, of New York, N. Y., has now been translated into Chinese by Drs. K. E. Wu and C. L. Mei, and the entire Series has been published for the Nurses Association of China by the Kwang Hsueh Publishing House, Shanghai.

NEW YORK STATE ASSOCIATION OF PUBLIC HEALTH LABORATORIES

AT the 23rd Annual Meeting of the New York State Association of Public Health Laboratories, the following officers were elected:

President, Gilbert Dalldorf, M.D., Grasslands Hospital Laboratory; Vice-

President, Charles M. Carpenter, M.D., Rochester Health Bureau Laboratories; Secretary-Treasurer, Mary B. Kirkbride, Sc.D., State Laboratory, Albany; Members of the Council include Orren D. Chapman, M.D., Bureau of Laboratories, Department of Health, Syracuse, and Arthur W. Wright, M.D., Albany Hospital and Albany Medical College Laboratories.

CANCER RESEARCH AWARD

IT has been announced that the Anna Fuller Memorial Prize for cancer research has been awarded to five English scientists of the Research Institute at the Royal Cancer Hospital, London. This amount of \$7,500 will be shared equally by Ernest Laurence Kennaway, director of the institute; James Wilfrid Cook, Colin Leslie Hewett and Izrael Hieger, chemists; and William Valentine Mayneord, physicist.

The award is made upon the recommendation of the president of the American Medical Association, the dean of the Johns Hopkins Medical School, and the dean of the Harvard Medical School.

CHALMERS GOLD MEDAL

THE council of the Royal Society of Tropical Medicine and Hygiene in London has awarded the Chalmers Gold Medal for 1939 to Dr. Max Theiler, of the International Health Division of the Rockefeller Foundation, "in recognition of research of outstanding merit contributing to the knowledge of tropical medicine or tropical hygiene, particularly in reference to yellow fever and the possibility of producing the vaccine by the use of attenuated virus."

The medal was presented at the annual general meeting of the Society at Manson House, London, on June 15.

SOUTH DAKOTA ASSOCIATION CHANGES NAME

THE South Dakota Public Health Association has changed its name to the South Dakota Tuberculosis Association.

CHANGES IN SAVANNAH, GA.

ON November 3, 1938, there occurred the death of Dr. Victor H. Bassett, Health Officer for the City of Savannah and the County of Chatham, as well as that of Dr. Alfred Larson, the Assistant Health Officer. In the interim, Dr. T. H. D. Griffiths, Senior Surgeon, U. S. Public Health Service, and Director of the Henry R. Carter Memorial Laboratory, Savannah, was appointed Acting Health Officer until the appointment of Dr. Clarence D. Hart, who took office on April 7. After only three days' service, Dr. Hart died suddenly on April 10, 1939. Again Dr. Griffiths assumed the position of Acting Health Officer. On May 1, 1939, Dr. Charles C. Hedges, Senior Medical Officer of the Federal Trade Commission, Washington, and the former Health Officer of Isle of Wight, Nansemond and Suffolk Counties, Va., was appointed as Health Officer of Savannah and Chatham County, assuming his duties on May 8. Dr. Glenn J. Bridges has been appointed Assistant to Dr. Hedges.

PERSONALS

Central States

LAWRENCE A. BERG, M.D.,† formerly Director of the Menominee County, Mich., Health Department, has been appointed to take charge of the newly organized health unit of St. Joseph County, with headquarters in Centerville.

CONRAD ARNOLD ELVEHJEM, Ph.D.,† Professor of Agricultural Chemistry of the University of Wisconsin, Madison, Wis., was awarded a prize

of \$1,000 at the closing meeting of the American Institute of Nutrition in Toronto, April 26, for his discovery that nicotinic acid would cure pellagra.

BESS EXTON, C.P.H.,† has been appointed Assistant in Health Education on the staff of the American Association for Health, Physical Education and Recreation. Miss Exton was formerly Executive Secretary of the Genesee County Tuberculosis Association, Flint, Mich.

DR. MARCOS FERNAN-NUNEZ, Professor of Pathology and Bacteriology, of the Marquette University School of Medicine, Milwaukee, Wis., has been appointed Chairman of the Cancer Committee of the State Medical Society of Wisconsin, succeeding WILLIAM D. STOVALL, M.D.*

C. O. SAPPINGTON, M.D., DR.P.H.,* of Chicago, Ill., has been named winner of the W. S. Knudsen Award for the Most Outstanding Contribution to Industrial Medicine during 1938-1939, at the recent convention of the 24th Annual Meeting of the American Association of Industrial Physicians and Surgeons, at Cleveland, Ohio. The award was made on the basis of Dr. Sappington's new book, *Medicolegal Phases of Occupational Diseases*.

Eastern States

S. S. GOLDWATER, M.D.,* Commissioner of Hospitals of New York, N. Y., was awarded an Honorary degree of Doctor of Public Health by New York University at the June commencement.

RUTH E. GROUT,† formerly the Director of Health Education in Cattaraugus County, N. Y., has received the Ph.D. degree from Yale at the June commencement, and has accepted an appointment as Senior

* Fellow A.P.H.A.

† Member A.P.H.A.

Supervisor of Health Education in the Health and Safety Department of the Tennessee Valley Authority, Chattanooga. She has spent the past year at Yale under a fellowship from the American Association of University Women.

ANTHONY M. LOWELL, C.P.H.,[†] has resigned his position as Research Secretary with the Philadelphia, Pa., Health Council, in order to accept the position of Assistant Statistician in the Research Service of the New York City Tuberculosis and Health Association.

DR. ROBERT C. SELLEW has been appointed Health Officer of Canaan, Conn.

DR. CHARLES K. SKRECZKO, JR., has been appointed Health Officer of Shelton, Conn., to succeed DR. WILLIAM S. RANDALL.

WILSON G. SMILLIE, M.D., DR.P.H.,* Director of Public Health at the Cornell College of Medicine, New York, N. Y., was awarded an honorary degree of Doctor of Science by Colorado College, Colorado Springs, in June.

DR. JOSEPH S. STYGAR has been appointed Health Officer of Derby, Conn., to succeed DR. THOMAS F. PLUNKETT.

RICHARD W. WEISER, M.D., Medical Director of Public Schools in Kenmore, N. Y., has been appointed Executive Secretary of the Cincinnati Social Hygiene Society to succeed CARL A. WILZBACH, M.D.,* who recently became City Health Commissioner.

Southern States

DR. ONEAL L. ATKINSON has been appointed Health Officer of Hampton, Ark.

DR. MILLARD B. BETHEL, of Statesville, N. C., has been appointed Health Officer of Cabarrus County, succeeding DR. JOHN S. ANDERSON, resigned.

DR. OTHO C. BOWMER, of Corsicana, Tex., was recently elected Health Officer of Navarro County.

DR. FRANK B. BOYLE, of Big Springs, Tex., has been appointed Health Officer of Howard County.

GLENN J. BRIDGES, M.D., has been appointed Deputy Health Officer of the City of Savannah and County of Chatham, Ga.

DR. ROLAND A. BROWN, of Macon, Ga., has been appointed Assistant City-County Health Officer of Bibb County, succeeding DR. HERBERT F. LARAMORE, who has accepted a position on the staff of the U. S. Veterans' Hospital in Los Angeles.

DR. ALBERT S. J. CLARKE, formerly of Clarendon, has been transferred as Health Officer in charge of District No. 16, at Ozark, Ark.

DR. LEE E. EDENS has been appointed Health Officer of Austin, Tex., to succeed DR. DURWOOD L. DODD.

J. W. ERWIN, M.D.,[†] of Blountville, Tenn., has been appointed Health Officer of Sullivan County, to succeed FRED L. MOORE, M.D.,[†] resigned.

CHARLES C. HEDGES, M.D., of the Federal Trade Commission, Washington, D. C., assumed his duties on May 8 as Health Officer of Savannah, Ga., and the County of Chatham.

DR. WALTER O. MCCAMMON, of Springfield, Ky., has been appointed Health Officer of Washington County, to succeed the late DR. WILLIAM R. THOMPSON.

DR. WILLIAM F. MCCARTHY has been appointed Health Officer of Jackson County, Mo.

FRAY O. PEARSON, M.D., C.P.H.,[†] of Livingston, Tenn., has been appointed Health Officer of Hamilton County, to succeed DR. JESSE C. ELDRIDGE, of Chattanooga, resigned.

LOWELL J. REED, Ph.D.,* Dean of the

* Fellow A.P.H.A.

† Member A.P.H.A.

School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md., received the degree of Doctor of Science from the University of Maine at the June commencement.

RICHARD C. SHEPARD, M.D.,† of LaFayette, Ga., has resigned as Health Commissioner of Catoosa and Walker Counties, effective April 15, to engage in private practice.

DR. CHARLES M. SMITH, of Dixon, Ky., has resigned as Health Officer of Webster County.

DR. WILLIAM S. TERRY, JR., of Jefferson, Tex., was recently appointed Health Officer of Marion County.

DR. JAMES A. THRASH, of Columbus, Ga., Health Officer of Columbus and Muscogee Counties, has been elected Superintendent of the Muscogee County Tuberculosis Hospital.

ROY J. TURNER, M.D.,† has been appointed Health Officer of Fayetteville, Ark.

GARLAND L. WEIDNER, M.D.,† has been named Assistant Health Officer of Atlanta, Ga.

DR. ROBERT F. YOUNG, of Cartersville, Ga., has been appointed Commissioner of Health of Bartow County.

Western States

DR. JAMES D. COULTER, of Portola, Calif., has been appointed Health Officer of Plumas County.

DR. HARRY A. CRECELIUS, of Plains, Mont., has been appointed Physician and Health Officer of Sanders County.

DR. ENOS G. DENISON, of Sheridan, Wyo., has been appointed a member of the State Board of Health.

DR. JAMES L. FAULKNER, of Red Bluff, Calif., has been appointed Health Officer of Tehama County, succeeding DR. OTHO T. WOOD.

DR. RAY L. DRINKWATER, of Denver, has been appointed to a 6-year term on the Colorado State Board of

Health, succeeding DR. CHARLES A. DAVLIN, of Alamosa.

DR. WILLIAM E. FOUNTAIN, of Merced, Calif., has been appointed Health Officer of Merced County, succeeding DR. CLARENCE C. FITZGIBBON.

JACOB M. FURSTMAN, M.D.,* Health Officer of the Monrovia District, has been named administrative head of the Pomona Health District, Calif.

DR. ALBERT B. GRAY has been appointed Health Officer of Dorris, Calif., succeeding DR. PAUL F. DIEFFENBACHER.

DR. HARRY M. GRAYMAN has been appointed Health Officer of Dos Palos, Calif., to succeed DR. EDWIN A. PATTERSON.

CHARLES G. GROVER, D.D.S., of Denver, has been appointed to a 6-year term on the Colorado State Board of Health, succeeding DR. BEN BESHOR, of Trinidad.

RAYMOND G. HOWE, D.D.S., of Casper, Wyo., has been appointed a member of the State Board of Health.

REUBEN L. KAUFMAN, M.D., C.P.H.,† for many years District Health Officer at Whittier, Calif., under the Los Angeles County Health Department, has been appointed Health Officer of Riverside County, to succeed the late WENDALL A. JONES, M.D.†

MARSHALL C. KEITH, M.D.,† of Casper, Wyo., Secretary of the Wyoming State Medical Society, has been appointed State Health Officer.

JOSEPH A. MYERS, an attorney of Denver, Colo., has been appointed to a 6-year term on the Colorado State Board of Health, succeeding H. C. DOLPH, D.D.S., of Denver. This is the first time an attorney has served as a member of the state board.

DR. DAVID G. SCHMIDT has been appointed Health Officer of Larkspur, Calif., succeeding DR. CORNWALL C. EVERMAN.

* Fellow A.P.H.A.

† Member A.P.H.A.

DR. GERALD E. STARK, of Coquille, Ore., has been appointed Health Officer of Coos County, succeeding CHARLES L. COYLE, M.D.,† of Grants Pass, resigned.

DANIEL P. TRULLINGER, M.D.,† of Oregon City, Ore., has been appointed Health Officer of Clackamas County, succeeding COURTNEY M. SMITH, M.D.,† resigned.

DR. GEORGE F. TURMAN, of Missoula, Mont., was named Chairman of the State Board of Health, succeeding DR. ENOCH M. PORTER, of Great Falls, at the Board's meeting in Helena, April 6.

FOREIGN

WALTER C. EARLE, M.D.,† of Cuernavaca, Morelos, Mexico, has been appointed Director of the Campaign-Urbana Health District, Illinois.

DEATHS

MAURICE BRODIE, M.D.,* of the Department of Laboratories, Providence Hospital, Detroit, Mich., died May 9, at the age of 35 years. He was formerly in charge of infantile paralysis research at the Bureau of Laboratories, New York City Health Department.

CLARENCE D. HART, M.D., C.P.H.,* formerly Director of the District Health Unit of Newberry, Mich., from April, 1935, to April, 1939, died in April, 3 days after reaching Savannah, Ga., where he was to have taken up his duties as Health Officer of the City of Savannah and Chatham County.

CHARLES H. MAYO, M.D.,† of the Mayo Clinic, Rochester, Minn., and for many years Health Officer of Rochester, died May 26.

* Fellow A.P.H.A.

† Member A.P.H.A.

Results of Bacterial Plate Counts of Milk on Three Media and at Two Temperatures of Incubation

C. A. ABELE, CH.E., F.A.P.H.A.

*Referee, Committee on Standard Methods for the Examination of
Milk and Dairy Products; Director, Division of Inspection, State
Department of Public Health, Montgomery, Ala.*

THE publication of the Seventh Edition of *Standard Methods for the Examination of Dairy Products*, in which is prescribed a change in culture medium from the present standard nutrient agar to a new standard nutrient agar known as tryptone-glucose-extract-milk agar, makes it desirable to present the reasons for this change.

Those who have been active in seeking improvements in the culture medium for the bacteriological plating of milk and dairy products are familiar with the various developments antecedent to the present study conducted by the Committee on Standard Methods for the Examination of Dairy and Food Products. In order that others may understand the motives and objectives of the committee, the following brief history is presented.

INTRODUCTION

Comparative studies with agars of different composition and with different temperatures of incubation were carried

out under the auspices of the American Public Health Association before the first edition of *Standard Methods of Milk Analysis* was published in 1910. Again in 1915 Conn¹ conducted a comparative study of plate count results in four laboratories, using two modifications of the standard nutrient agar prescribed by the "Standard Methods Report" of that period. His conclusions were to the effect that the modifications employed in making media had a minor effect upon the plate count, as compared with such other factors as differences in technic. Hatfield² and Kilbourne³ conducted similar studies in 1918 with parallel results.

The composition of the culture medium continued a subject for discussion and study, and important changes were made in the second, third, fourth, and fifth editions. The composition of the agar remained unchanged in the sixth edition, but there was general appreciation of the fact that the agar in use was unsatisfactory in several respects.

In 1934 Bowers and Hucker presented a preliminary report of a study of the effect of the substitution of yeast extract for beef extract in the standard nutrient agar formula, and also of the effect of the addition of a fermentable carbohydrate. The substitution of yeast extract did not materially increase the count, but it was found that the addition of glucose to standard nutrient agar resulted in an appreciable increase in count and also increased the colony size. In March, 1935, these authors published a report of a more extensive study on the composition of culture media for the bacteriological examination of milk.⁵ On the basis of their findings they suggested the use of a medium for the grading of milk by counts, to consist of 0.5 per cent tryptone (a casein digest peptone), 0.1 per cent glucose, 0.5 per cent skim milk, and agar.

In May, 1935, Breed⁶ as Chairman of the Committee on Standard Methods of Dairy and Food Products, urged milk control laboratory directors to prepare and use this and other suggested media in comparison with standard nutrient agar.

Since 1921 the literature has been interspersed with discussions of and references to the effect upon bacterial plate counts of milk, of irregularities in the temperature of incubation caused by inefficient incubator construction.⁷⁻¹³ These led to an organized study of the construction of bacteriological incubators, and the effect of various methods of loading upon the temperatures of individual plates.¹⁴ This work was followed by a study of the effect of carefully controlled specific temperatures ranging from 21°C. to 55°C., upon the plate counts of the same sample of milk.¹⁵ The latter investigators, Pederson and Yale, found that the apices of most of the plotted curves of maximum average plate counts occurred at 32°C \pm 2°; and they recommended

the adoption of this incubation temperature as the standard. It was pointed out that higher counts are obtained at 32°C., yielding a truer measure of milk quality; that there is a smaller error in counts occasioned by temperature variation in incubators operated at this temperature; and that the constancy of counts on split samples incubated at 32°C. is greater than that of those incubated at 37°C.

It will be observed that these developments in composition of culture media and temperatures of incubation were somewhat coincidental. Proposals for changes in Standard Methods resulting therefrom aroused widespread interest and discussion, both within the milk industry and among milk control authorities, and were the inspiration for a number of studies and reports.¹⁶⁻¹⁹ Meanwhile, independently of these studies on the composition of standard agar, a medium was developed by the American Association of Medical Milk Commissions for the plating of certified milk, and a coöperative study of the effect of this medium as compared with standard nutrient agar on milk plate counts, was conducted and reported.²⁰

The studies stimulated by the present Committee on Standard Methods with so-called T-G-M agar (Tryptone-glucose-skim milk agar) were summarized for the committee by Yale.²¹ In all of these studies, published and unpublished, a certain number of samples yielded higher counts on the old standard agar. Unpublished experimental work carried out under the auspices of the committee having indicated that a return to the use of beef extract would lessen the number of instances where counts on the old agar were higher, the committee decided to make the studies reported upon in this paper with T-G-E-M agar (Tryptone-glucose-extract-milk agar). As this agar contains the same amount of beef extract as the present standard agar it re-

sembles this agar more closely than does the T-G-M agar. It was also decided to include the A.A.M.M.C. agar, as recommended in its latest formula, in this official study. The latter agar also contains beef extract. Incubation of all plates was to be carried out at 37°C. and at 32°C.

PART I

AGAR FORMULAE

The formula of the T-G-E-M agar used in this study was as follows:

T-G-E-M Agar

Bacto-Tryptone	5 gm.
Bacto-Beef Extract	3 gm.
Glucose	1 gm.
Skim milk	10 cc. (where dilutions were greater than 1:10).
Agar	15 gm.
Water	1,000 cc.
Reaction pH 7.0	

Then, because of the similarity of the latest form of the A.A.M.M.C. agar, in both composition and reported effect, this medium was also included in the study. The composition of the A.A.M.M.C. agar was:

Nutri Peptone	10 gm.
Beef Extract	3 gm.
Dextrose	1 gm.
Salt	5.0 gm.
Agar	15 gm.
Water	1,000 cc.
Reaction pH 7.0 to 7.2	

The "Tryptone" peptone used in the T-G-E-M agar is a digested casein that has been on the market for a number of years. It has generally been found to be a very satisfactory peptone and was thought to be an especially desirable peptone for use in growing organisms found in milk.

With respect to the temperature of incubation, it was recognized to be the

function and obligation of the committee to determine the degree to which the adoption of 32°C. incubation affects counts, and to what extent it would disturb existing concepts of milk quality standards, and to consider the practicability and expediency of the adoption of this temperature of incubation as the standard procedure.

PRIMARY REQUISITES FOR THE STUDY PROCEDURE

Cone's¹⁷ comments on the findings of Kelly¹⁶ impressed upon the committee the imperative need for uniformity of conditions and procedure in the conduct of this study in a number of public health laboratories. Accordingly, an Outline of Procedure, prescribing adherence to the instructions of Standard Methods, 1934, and amplified by insistence upon the following specific requirements, was formulated:

1. Calibrated pipettes
2. Level marked dilution containers
3. Equipment and materials for determining the reaction of media colorimetrically, or more accurately, if preferred
4. Accurately tempered media (when poured)
5. A 32° C. and a 37° C. incubator maintained at constant temperatures
6. Standardized thermometers
7. A Quebec Colony Counter, or other satisfactory illuminating and counting device
8. Breed-count pipettes, slides, and staining equipment
9. Competent and reliable personnel

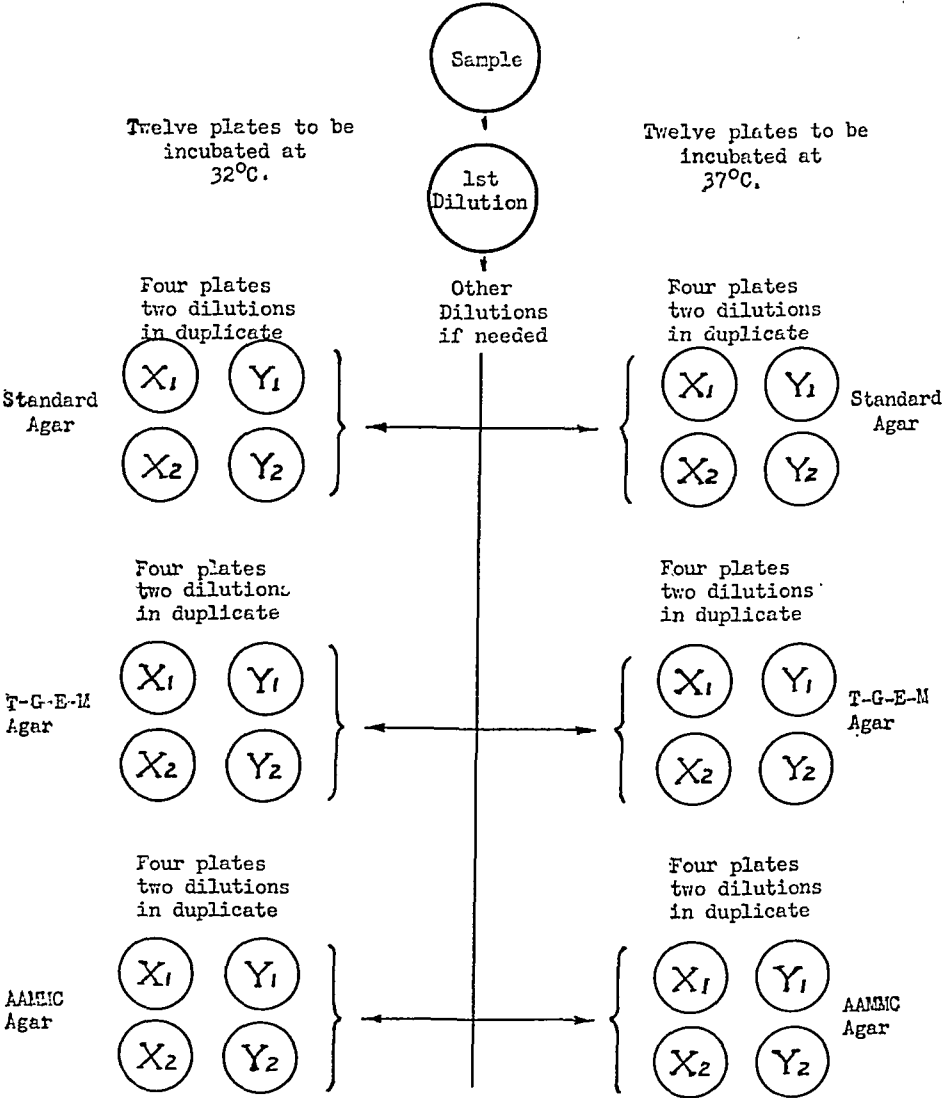

A report-form was devised providing blanks for identification of each sample; its nature, age, and temperature when collected and when plated; type of pipettes and method of dilution employed; reaction and temperature of media when poured; temperature readings of three thermometers kept in the incubators, at intervals during the incubation period; the nature of the counting device used; and, finally, the plate count results. Two sets of plates

of two dilutions each, of each agar and at each temperature under test, were prescribed. The lay-out for any one sample is given in the accompanying schematic chart. (Spaces for reporting dilution counts were lettered on the report form to correspond to the lettered plates in this chart.)

The pouring and counting of two sets of plates was prescribed in order to enable the Referee to judge the accuracy of results in terms of correspondence in count between the duplicate sets of plates, and thus to be in position to discard results of a dubious nature.

SCHEMATIC CHART FOR PLATING SAMPLES

Instructions: Use 1.0 cc. of dilution water in each of the "X" plates, whatever the degree of dilution.
Use either 0.1 cc. of the same dilution, or 1.0 cc. of the next higher dilution, in each of the "Y" plates.

COÖPERATING LABORATORIES

Preliminaries having been completed, the directors of 48 public health laboratories were invited to participate in the study. Although 10 found themselves in position to do so and accepted the invitation, only 7 really participated in the study and filed reports. The numbers and natures of the samples examined by the participating laboratories are given in the Tabulation A.

It is quite obvious that in the cases of raw certified milk, raw certified cream, and pasteurized certified milk, the numbers of sample results sub-

G	0	0	9	0	0	0	9
Totals	15	5	40	247	23	5	335

mitted are too small to yield analyses of statistical significance. This is true also, though to a lesser extent of raw milk and pasteurized cream. Consequently, the deductions submitted in this report are based mainly upon the analyses of the results of the platings of pasteurized milk.

The laboratories participating in this study (the names of which are purposely not listed in the order in which laboratory designations appear in the tabulations) are:

Bureau of Laboratories, Detroit Department of Health, Detroit, Mich. Dr. Joseph A. Kasper, Director; Gail A. Smith, laboratory medical aid

Division of Bacteriology, New York State Experiment Station (Cornell University), Geneva, N. Y., Dr. G. J. Hucker, Chief in Research; William Walter, Bacteriologist

VISÉ OF REPORTS RECEIVED

The desirability of checking every report very carefully before classifying and recording the results was indicated before the study had proceeded far. It was also evident that arbitrary rules for deciding upon the results to be used and those to be discarded must be adopted. Because of the fact that the Outline of Procedure formulated for this study prescribed duplicate sets of plates of two dilutions each, the directions for arriving at the final count given in Standard Methods, 1934, do not clearly cover some of the situations encountered. Consequently, the following rules of procedure governing acceptance or rejection of counts, to be applied in addition to those of Standard Methods, were arbitrarily adopted and adhered to:

1. Counts based only upon obviously overgrown (over 400 colonies) or underdeveloped or too highly diluted (less than 20 colonies) plates were to be discarded.

2. When the ratio of the calculated counts on the two plates (X1 and X2, or Y1 and Y2) of either set exceeded 1:2.5, the final count was to be discarded.

3. When the computed final counts of the two sets of plates varied to an extent that the deviation of each from their mean exceeded 25 per cent of the mean, the final count was to be discarded.

The application of these rules, liberal as they may appear, resulted in the discarding of a number of the counts reported. Where necessary, corrections were made of arithmetical errors in the

reported counts and to adhere to *Standard Methods of Milk Analysis* procedures.

NATURE OF THE FINDINGS

Graphic presentation of the results reported, whenever possible and practical, has been followed in the preparation of this report. "Scatter" diagrams on a semi-logarithmic scale, have been employed to demonstrate the dispersion or "scatter" of counts obtained on the several media and at the two temperatures of incubation studied. Every count on standard agar at 37°C. is hypothetically located on the zero abscissa of the chart at the point on the

CHART No. 1—Deviation of counts on Standard Agar, at 32° C. from those on Standard Agar, at 37° C. 166 Counts. Average deviation: +64.3%.

Cumulative Deviations: Counts under 5,000 per cc., +164.0%; under 10,000 per cc., +104.7%; under 25,000 per cc., +95.1%; under 50,000 per cc., +115.4%; under 100,000 per cc., +98.3%; under 200,000 per cc., +70.0%; under 500,000 per cc., +64.3%.

Counts Exceeding Limit Because of Increase: 30,000 per cc., 13.1%; 50,000 per cc., 12.8%; 100,000 per cc., 9.1%; 200,000 per cc., 43%.

TABULATION B

INDIVIDUAL DEVIATIONS OF COUNTS OF PASTEURIZED MILK ON STANDARD AGAR AT 32° C.

Range	Total	Increased	Per cent	Decreased	Per cent	Identical	Per cent
Under 5,000	35	35	100.0	0	0.0	0	0.0

ordinate corresponding to its magnitude. This is the "norm" so termed by Kelly,¹⁶ and is the base from which the deviation of the count on the same sample, under the specific conditions studied, is measured.

Caution must be exercised to avoid an erroneous impression of the grouping of the points representing percentages of deviation on these charts. If the whole chart were in each case constructed on the scale applying to the range 1,000 to 10,000, it would be over 16 feet long, and the points above 10,000 would be proportionately more widely scattered.

Wherever coincidence of results was encountered it is indicated by the insertion of numbers applying to this point on the chart.

Standard Agar at 32°C.—Chart 1 presents the extent of the deviation of individual counts of pasteurized milk on standard agar at 32°C., from the counts of the same samples on standard

agar at 37°C. One hundred and sixty-six counts are located. The deviations range from minus 56 per cent to plus 1,260 per cent. The deviations are tabulated by ranges of magnitudes, as shown in Tabulation B.

The average deviation of all of the 166 counts at 32°C. from those at 37°C.—not the average of the percentage deviations—was 64.3 per cent upward. The average deviation in each range of magnitude, and by laboratories, is given in the recapitulations of Table I.

T-G-E-M Agar at 37°C.—Chart 2 presents the extent of the deviation of individual counts of pasteurized milk on T-G-E-M agar, at 37°C., from the counts on the same samples on standard agar, at 37°C. One hundred and ninety-three counts are located. The deviations range from minus 49 per cent to plus 1,600 per cent. (This deviation on a count of 4,000 on standard agar at 37°C., and also one of

CHART No. 2—Deviation of counts on T-G-E-M Agar, at 37° C., from those on Standard Agar, at 37° C. 193 Counts. Average deviation: +48.0%.

Cumulative Deviations: Counts under 5,000 per cc., +127.0%; under 10,000 per cc., 93.9%; under 25,000 per cc., +92.2%; under 50,000 per cc., +81.7%; under 100,000 per cc., +67.8%; under 200,000 per cc., +54.7%; under 500,000 per cc., +48.0%.

Counts Exceeding Limit Because of Increase: 30,000 per cc., 10.2%; 50,000 per cc., 11.4%; 100,000 per cc., 6.7%; 200,000 per cc., 3.2%.

1,329 per cent on a count of 7,700 are not shown in this chart.) The numbers of deviations are tabulated, by ranges of magnitudes, as shown in Tabulation C.

The average deviation of all the 193 counts on T-G-E-M agar at 37°C. was 48.0 per cent upward. The average deviation in each range of magnitude and by laboratories, is given in the recapitulations of Table I.

The greater concentration or lesser dispersion, of points between the norm and plus 50 per cent deviation is to be noted on this chart when compared with Chart 1.

T-G-E-M Agar at 32°C.—Chart 3 presents the extent of deviation of individual counts of pasteurized milk on T-G-E-M agar, at 32°C. from the counts on the same samples on standard agar at 37°C. One hundred and sixty-six counts are located. The deviations range from minus 36.8 per cent to plus 1,110 per cent. The numbers and directions of deviations, by ranges of magnitudes, are tabulated as shown in Tabulation D.

The average deviation of all the 166 counts on T-G-E-M agar at 32°C. from those on standard agar, at 37°C., was 113.7 per cent upward. The average

Total	33	131,206	27	190,063	+16.1	+21.6	23	121,778	+54.8	34	166,962	+24.2	25	222,984	+15.2

the right of the norm—percentage increase—is much more pronounced in Chart 3 than in Chart 1, and in only 6 cases was the deviation negative, representing a decreased count. The only variable in Charts 1 and 3 being the medium employed, it is obvious that T-G-E-M agar yields generally higher counts than standard agar. Chart 3 therefore corroborates Chart 2.

A.A.M.M.C. Agar at 37°C.—Chart 4 presents the extent of the deviation of individual counts of pasteurized milk on A.A.M.M.C. agar at 37°C., from counts of the same samples on standard agar at 37°C. One hundred and eighty-

nine counts are located. The deviations range from minus 76.0 per cent (a decrease from 65,000 on standard agar at 37°C. to 16,000 on A.A.M.M.C. agar) to plus 991 per cent. The deviations, by ranges of magnitudes and direction, are shown in Tabulation E. The average deviation of all the 189 counts on A.A.M.M.C. agar at 37°C. from those on standard agar at 37°C. was 35.8 per cent upward. The average deviation in each range of magnitude and by laboratories is given in the recapitulations of Table I.

Comparison of Charts 2 and 4 emphasizes the greater concentration

CHART NO. 4—Deviation of Counts on A.A.M.M.C Agar, at 37° C., from those on Standard Agar, at 37° C. 189 Counts. Average deviation: +35.8%.

Cumulative Deviations: Counts under 5,000 per cc., +69.1%; under 10,000 per cc., +49.9%; under 25,000 per cc., +39.2%; under 50,000 per cc., +60.3%; under 100,000 per cc., +47.1%; under 200,000 per cc., +40.8%; under 500,000 per cc., +35.8%.

Counts Exceeding Limit Because of Increase: 30,000 per cc., 7.4%; 50,000 per cc., 9.1+; 100,000 per cc., 5.7%; 200,000 per cc., 3.2%.

TABULATION E

INDIVIDUAL DEVIATIONS OF COUNTS OF PASTEURIZED MILK ON A.A.M.M.C. AGAR AT 37° C.

Range	Total	Increased	Per cent	Decreased	Per cent	Identical	Per cent
Under 5,000	46	33	71.8	13	28.2	0	0.0

Total	163	146	89.6	15	9.2	2	1.2

individual counts of pasteurized milk on A.A.M.M.C. agar, at 32°C., from the counts of the same samples on standard agar at 37°C. One hundred and sixty-three counts are located. The devia-

tions range from minus 40 per cent to plus 1,750 per cent (on a count of 8,200 on standard agar at 37°C., an increase to 150,000 on A.A.M.M.C. agar at 32°C.—not shown on this

CHART No. 6—Comparative Deviation of Counts on A.A. M.M.C. Agar from counts on T-G-E-M Agar, at 37° C., and at 32° C.
The percentages of deviation of the screened counts are indicated by the solid spots.

chart). The deviations are tabulated by ranges of magnitudes and direction as shown in Tabulation F.

The average deviation of all the 163 counts on A.A.M.M.C. agar at 32°C. from those on standard agar at 37°C. was 90.8 per cent upward. The average deviation in each range of magnitude and by laboratories, is given in the recapitulation of Table I. When compared with Charts 1 and 3, it is to be noted that the dispersion of points on Chart 5 is greater than that on Chart 1, but less than that on Chart 3.

The data from which Charts 1 to 5 were made are summarized in Table I.

Caution is advised in considering the average total counts and percentages of average deviation of the counts on the several media at the two temperatures for a slight deviation in one direction on a very high count may balance and nullify considerable deviation in the opposite direction on a number of lower counts. For this reason, the per-

centages of deviation of the average counts in the several ranges of count magnitude on standard agar at 37°C. are probably more significant than are the totals.

COMPARISON OF COUNTS ON T-G-E-M AND ON A.A.M.M.C. AGARS, AT 37°C. AND AT 32°C.

Since the primary purpose of the committee in conducting this study was to obtain data upon which to predicate a decision concerning an improvement in culture medium and a change in temperature of incubation, a more direct comparison of the two media under consideration than is possible by means of individual comparisons of each with standard agar appeared desirable. Such comparisons of counts on these two media at both 37°C. and 32°C., are presented in Chart 6.

In both instances the counts on T-G-E-M agar constituted the bases from which were computed the per-

TABULATION H

RELATIONSHIP OF COUNTS ON A.A.M.M.C. AGAR TO COUNTS ON T-G-E-M AGAR

Incubation Temperature	No. of Counts	Increased		Decreased		Identical	
		No.	Per cent	No.	Per cent	No.	Per cent
37° C.	183	56	30.6	119	65.0	8	4.4
32° C.	159	47	29.6	108	67.9	4	3.5

centage deviations of the counts of the same samples on A.A.M.M.C. agar.

Comparisons of Chart 2 with 4, and of Chart 3 with 5 indicate that the dispersion of counts from the norm, or the increase in count is greater on T-G-E-M agar than on A.A.M.M.C. agar. The recapitulations of Table I confirm this. It is to be expected, therefore, that when the magnitudes of counts on A.A.M.M.C. agar are compared with those of the same samples on T-G-E-M agar, a negative deviation will be noted.

The average deviation by count magnitudes was by no means uniform, either in percentage or in direction. This is confirmed by Tabulation G.

It is to be noted that, except in two ranges of magnitudes of counts on T-G-E-M agar, at 37°C., the average deviation of the counts on A.A.M.M.C. agar was always negative; that is, the T-G-E-M agar counts were, on the whole, the higher.

In terms of numbers of individual counts, the relationships of A.A.M.M.C. agar counts to those on T-G-E-M agar, at the two temperatures, were as shown in Tabulation H.

It is quite clear, then, that regardless of the manner in which the relationship

is determined, counts on T-G-E-M agar were, on the whole, higher than those on A.A.M.M.C. agar.

(The difference in designation of points on Chart 6 is explained in Part II).

RAW MILK COUNTS ON THE SEVERAL MEDIA, AND AT THE TWO TEMPERATURES OF INCUBATION

The number of reports of results of the platings of raw milk was so small (34 was the maximum number on which comparisons were possible) that a scatter diagram would be rather valueless. However, summaries of the data on this type of sample, similar to those given in one of the recapitulations of Table I, are given in Table II.

A comparison of Table II with the parallel portion of Table I reveals the fact that the average deviations of the counts of raw milk are consistently lower than those of pasteurized milk. In only 5 of the 35 parallel ranges and culture conditions is the average deviation greater in the case of raw milk than in the case of pasteurized milk.

However, no conclusions may be drawn from the average behavior of groups of 6 or less samples, even though they be in the same general magnitude

TABULATION I

COMPARISON OF AVERAGE PERCENTAGE DEVIATIONS

	Stand. Agar—32° C.		T-G-E-M Agar—37° C.		T-G-E-M Agar—32° C.		A.A.M.M.C. Agar—37° C.		A.A.M.M.C. Agar—32° C.	
	Avg. Count	Per cent Dev.	Avg. Count	Per cent Dev.	Avg. Count	Per cent Dev.	Avg. Count	Per cent Dev.	Avg. Count	Per cent Dev.
Past.	54,737	+64.3	46,649	+48.0	70,133	+113.7	42,954	+35.8	63,292	+90.8
Raw	190,363	+16.1	159,558	+21.6	121,778	+ 54.8	166,962	+24.2	222,984	+15.2

range. The average deviations for the whole groups of pasteurized milk and raw milk counts are somewhat more significant, and bear a rather striking comparison to one another, as Tabulation I shows.

As previous investigators who have examined larger numbers of samples with T-G-E-M agar have reported similar findings, a possible and probable explanation of the lower average percentage of deviation in the case of raw milk is that the bacterial flora of raw milk grows better on the present standard agar than does the flora of pasteurized milk.

PASTEURIZED CREAM COUNTS ON THE SEVERAL MEDIA AND AT THE TWO TEMPERATURES

Seventeen of the 23 pasteurized cream counts reported were usable, but this number was too small to be segregated into groups, according to magnitudes, from the findings of which conclusions might be drawn. Because, however, of the striking divergence of some of the figures for pasteurized cream from the parallel figures for pasteurized milk (Table I) and raw

milk (Table II), summaries and computations applying to the whole set of reports on this product are presented in Tabulation J.

It is worthy of note that the effect of 32°C. incubation was greater than the effect of the use of either of the improved agars. This is in line with previous findings that have indicated the presence of a low temperature flora in pasteurized cream and ice cream mixes whose presence is not indicated in any way when incubation is at 37°C.

ACTION OF THE COMMITTEE

The foregoing presentation of data constitutes an amplification of the preliminary report²¹ placed before the Committee on Standard Methods for the Examination of Dairy and Food Products on October 25, 1938.

Because of the more universal increase of the plate count on T-G-E-M agar than on the A.A.M.M.C. agar, both from the standpoint of frequency and extent of increase, the Tryptone-glucose-extract-skim milk (T-G-E-M) agar was selected as the standard agar. It was recommended that it be put into use, from and after July 1, 1939.²²

TABULATION J

COMPARISONS OF RAW AND PASTEURIZED MILK AND PASTEURIZED CREAM COUNTS

		Milk Raw	Milk Pasteurized	Cream Pasteurized
Standard	No. of Counts	27	166	15

at 37° C.	Average Deviation	+24.2%	+35.8%	+20.4%
A.A.M.M.C.	No. of Counts	25	163	14
Agar	Average Count	222,984	63,292	201,228
at 32° C.	Average Deviation	+15.2%	+90.8%	+366.5%

This action of the committee was supported by the Coördinating Committee on Standard Methods of the Laboratory, and Food and Nutrition Sections, and by the Committee on Research and Standards, and the Governing Council of the Association.

The much greater increase in counts from incubation at 32°C., indicating that serious difficulty might be met in enforcing existing plate count limits and standards; the prospect that many public health laboratories could not be equipped with 32°C. incubators within a relatively short interval; and the difficulties of maintaining the incubator temperature at 32°C. (89.4°F.) while atmospheric temperatures sometimes exceed 38°C. (100°F.)—these practical considerations led the committee to retain 37°C. as the standard temperature of incubation. But, in order to emphasize the need for the correction of erroneous technics, the committee specified that the incubation temperature tolerance shall be in a negative direction only, and shall lie between 35°C. and 37°C.²²

PART II

The substitution of T-G-E-M agar for standard agar and the retention of 37°C. as the temperature of incubation having been accepted by the Association, an analysis of the data secured in the study made by the committee, for the purpose of ascertaining, if possible, the extent to which milk and dairy products plate counts may be expected to be increased by the use of the T-G-E-M agar, seems pertinent and apropos.

Before undertaking such an analysis—or, at least, before any credence is to be placed in the conclusions drawn from such an analysis—it must be assumed that the counts reported were essentially correct; and, it must also be recognized that the deductions and conclusions drawn from the analyses of

these counts may be applied only to groups of counts which are also essentially correct.

ANALYSES OF FINDINGS

The effect upon milk and cream plate counts of the change to T-G-E-M agar is of interest to milk producers, milk pasteurizers, and milk quality control authorities, particularly in areas in which the average bacterial plate count is a factor in the determination of grade, or of the premium paid for milk on the basis of the count.

The limit of deviation in an upward direction (percentage increase) permissible for a count at any given magnitude on standard agar at 37°C. to remain within certain numerical limits under other conditions of culture, is given for 4 frequently applied bacterial plate count limits, on each of Charts 1, 2, 3, 4, and 5. Counts which have fallen beyond the limits fixed are those the points of which are located in the area below the ordinate for the limiting count (30,000, 50,000, 100,000, or 200,000 per cc.) and to the right and above the curve for this limiting count.

In the following tabulations only those upper limits are used which occur in the U. S. Public Health Service Milk Ordinance.

The numbers and percentages of instances in which use of the T-G-E-M agar at 37°C. increased the standard agar counts at 37°C., beyond the limits for certain grades of milk and cream, are given in Tabulation K.

The percentages in the foregoing tabulations, it must be observed, apply only to the chance arrangements of magnitudes composing the groups on which these percentages were computed. For instance, in the case of pasteurized milk, with a limiting count of 30,000 per cc., less than 5 per cent of the counts were in the upper sixth of the range 0–30,000; but the per-

TABULATION K

PASTEURIZED MILK—UPPER LIMIT 30,000 PER CC.

Range on Standard Agar	No. of Counts	Counts Over Limit (30,000) on T-G-E-M Agar	
		No.	Per cent

centage of counts over 30,000 per cc. on T-G-E-M agar, in this sixth of the range, was 83.3 per cent.

It would be advantageous in any revision of bacterial plate count limits for grades of milk that may be necessary, if the increase in counts resulting from the use of the T-G-E-M agar might be estimated or prognosticated with a fair degree of accuracy. It appears, however, from a study of Tables I and II, that average deviations (increases) of 48.0 per cent and 21.6 per cent, respectively, resulting from plating of pasteurized milk and raw milk, respectively, on T-G-E-M agar, are by no means uniform throughout all ranges of magnitudes of counts on standard agar. In the case of pasteurized milk (Table I) there is almost a uniform decrease in the percentage deviation—all upward—between the ranges 0-5,000 and 210,000-500,000 per cc., the percentages being: 127.0, 80.3, 89.5, 71.6,

47.5, 27.2, and 7.0. Only the average deviation for the 21 counts in the range 51,000-100,000—47.5 per cent—approaches closely the average deviation for the whole group of 193 counts. In the case of raw milk the phenomenon of higher percentage deviations in the lower ranges of counts is not encountered, although the sub-groups in this group of 33 counts (Table II) are really too small to serve as representative samples. This is also true of the percentage deviations of pasteurized cream counts.

Nor is there a high degree of agreement in the percentage average increases (deviation) of counts on T-G-E-M agar (or, incidentally, on either medium at either temperature) on the part of the laboratories participating in the study (Recapitulation by Laboratories of Table I).

It appears, then, not to be possible or advisable to assume that a sample

of milk or cream yielding a count on standard agar within a certain magnitude range, would have yielded a count a certain definite percentage higher had it been plated on T-G-E-M agar; nor, conversely, that a count within a given range on T-G-E-M agar would have been a fixed percentage lower had it been plated on standard agar.

In order to check the effect of the method of determination and selection of count results upon the percentages of deviation in count, a more rigid set of criteria for closeness of correspondence between the computed counts of the two dilutions, and also between the calculated counts of the two sets of plates, was fixed. This resulted in the screening out of 55 to 63 per cent of the counts considered in the foregoing portion of this study. The same methods of analysis were applied to the smaller numbers of screened counts, with not significantly divergent results. It may reasonably be assumed, therefore, that other groups of counts determined with a degree of care comparable with those selected for this study, and of approximately the same proportionate magnitudes, would be similarly affected by the conditions of culture studied.

In Chart 6 the percentages of deviation of the screened counts are indicated by the solid spots, whereas those of the unscreened counts (other than those which appear among the screened counts) appear as open circles.

COMPARISONS OF THE FINDINGS OF THIS STUDY WITH THOSE OF OTHER STUDIES

It is quite possible that, because of major differences in the magnitudes of the standard agar at 37°C. counts of the milks examined in these several studies, the findings with respect to the effect of T-G-E-M agar at 37°C. of, for instance, Kelly,¹⁶ Bradfield,²⁰ and of this study are not closely comparable.

Nevertheless, a presentation of such of the results or findings of these three reports as are of the same general nature, may be of interest.

Kelly reports that the average count of 1,051 samples of Grade A pasteurized milk was increased 46 per cent, and that of 859 samples of Grade B pasteurized milk was increased 52 per cent, when plated on T-G-E-M agar at 37°C. Bradfield obtained an increase of 104 per cent in the average count of 71 samples of pasteurized milk. (The figure 274 per cent given in Table 20 of Bradfield's report is an arithmetic average of the 71 percentages of increase or decrease in count.) The average increase in the count of 193 samples of pasteurized milk reported for this study was 48 per cent (Table I). In the case of 86 screened reports of pasteurized milk, the counts increased 54 per cent on T-G-E-M agar at 37°C.

In the case of raw milk, Kelly reports a decrease of 7 per cent in the average count of 1,157 samples plated on T-G-E-M agar at 37°C. Bradfield obtained an increase 27.1 per cent in the average count of 159 samples (Table 1 of that report). In this study an increase of 21.6 per cent was obtained in the average count of 33 samples (Table II).

As stated heretofore, these percentages of deviation (increase or decrease) in the average counts of all the pasteurized milk or of all the raw milk samples examined are not really significant. A slight change in the ratio of high to low count samples in these groups would undoubtedly have altered these percentages. This is quite clearly demonstrated when the percentage increases in average count are calculated for the progressively larger groups of counts obtained by adding cumulatively the numbers of counts in the respective ranges of magnitudes, as given in Tabulation L.

TABULATION L
CUMULATIVE PERCENTAGES OF COUNT DEVIATION PASTEURIZED MILK

the numbers and percentages of the counts which were increased or decreased by plating on T-G-M agar and T-G-E-M agar at 37°C. has been made. See Tabulation M.

The groupings of count magnitude in this tabulation depart somewhat from those generally followed in this report, but were necessitated by the groupings in the report of Kelly. It is interesting to note that these groupings indicate that the T-G-E-M agar caused increases in counts even more regularly than the T-G-M agar.

SUMMARY

The results of a total of 335 milk (certified, raw, pasteurized, and certified-pasteurized) and cream (certified, and pasteurized) samples, plated on standard agar, Tryptone-glucose-extract-agar, and the American Association of Medical Commissions agar, and incubated at 32°C. and 37°C., by 7 laboratories, were analyzed.

Pasteurized Milk

An increase in count was observed in 70 per cent or more of the samples when plated on either T-G-E-M or A.A.M.M.C. agar, at 37°C., the average increases in count being, respectively, 48.0 and 35.8 per cent.

An increase in count was observed in 88 per cent of the samples when plated on standard agar at 32°C., the average increase being 64.3 per cent.

A cumulative increase in count was noted when samples were plated on either T-G-E-M or A.A.M.M.C. agar, at 32°C., the increases being, respectively, 113.7 and 90.8 per cent.

The T-G-E-M agar yielded generally higher counts than the A.A.M.M.C. agar, at both temperatures of incubation.

Raw Milk

The comparatively small number of results available for analysis places a

questionable value upon the analytical findings. However, the two modified media yielded increases in individual and average counts, but the cumulative effect of incubation at 32°C. was noted only in the case of T-G-E-M agar; the average increase in count was lower in the case of A.A.M.M.C. agar at 32°C. than at 37°C.

The analysis of the results on this small group of samples appears to corroborate the findings of other investigators that increases in counts on the modified agars are not so large in samples of low-count raw milk as in samples of low-count pasteurized milk.

Pasteurized Cream

Increases in average counts on T-G-E-M and A.A.M.M.C. agars at 37°C. paralleled or were not greatly divergent from those of raw and pasteurized milk at this temperature. But the percentages of increase in count on the three media, at 32°C., were two- to four-fold those in the case of pasteurized milk, and five- to twenty-four fold those of raw milk.

Although the counts of pasteurized cream were few in number, the findings were similar to those obtained in previous studies, in that there was distinct indication of the presence in these cream samples of bacteria which grow well at 32°C., even on standard agar, but do not develop at 37°C., even on the improved agars.

The use of T-G-E-M agar, selected as the standard after July 1, 1939, may be expected to increase beyond the legal limits such counts as on standard agar were, or would have been, close to the legal limit. This, however, will affect only milk supplies the counts of which, on standard agar, have not presented a true picture of bacterial content.

The findings of this study do not deviate significantly from those of previous investigators.

CONCLUSIONS

1. Because of the relatively small numbers of plate counts of raw milk and cream, and of pasteurized cream considered in this study, conclusions may be drawn with confidence only from the analyses of the data on pasteurized milk. The use of tryptone-glucose-extract-skim milk (T-G-E-M) agar at an incubation temperature of 37°C. resulted, in 60 to 90 per cent of the cases—varying inversely with the magnitude of the count—in an increase over the plate count on standard nutrient agar.

2. The percentage of such increase in count was extremely variable, although the percentage of average increase was greater in the lower than in the higher ranges of counts on standard nutrient agar.

3. In general, higher counts resulted from the use of T-G-E-M agar than from the use of the American Association of Medical Milk Commissions (A.A.M.M.C.) agar at incubation temperatures of 32°C. and 37°C., although the difference in average counts did not exceed 10 per cent.

4. The results of this study parallel those of other studies conducted, and corroborate the conclusions drawn therefrom.

5. There is no indication of a fixed ratio between counts on standard nutrient agar and those obtained by the use of either of the other media.

6. It follows that attempts to correlate or translate counts on T-G-E-M or A.A.M.M.C. agar to what they would have been had standard nutrient agar been used, or vice versa, are likely to be misleading.

7. Incubation at 32°C. in combination with the use of the modified agars, resulted in increases in plate count of considerably greater magnitude than were obtained by the use of these agars and incubation at 37°C.

ACKNOWLEDGMENTS

The writer is indebted to Dr. A. H. Robertson, Referee on Methods of Counting Bacteria in Dairy Products of the Committee on Standard Methods, for advice concerning the formulation of the Outline of Procedure for this study; to the writers of foregoing reports for analytical procedure and for the format of this report; to Dr. S. R. Damon and Cooper Brougher, Director and Assistant, respectively, of the Division of Laboratories of the Alabama State Department of Health for frequent suggestions and advice; and to Leonard V. Phelps, Director of the Division of Vital Statistics for mathematical assistance; and to Dr. Robert S. Breed for advice and assistance in the preparation of this report.

The committee is indebted to the laboratory directors named in Part I, together with their staffs, for the time and effort, and equipment devoted to the multiple examinations of numbers of milk samples.

Lastly, this study would not have been possible except for the liberality of Dr. H. G. Dunham of the Difco Laboratories, Detroit, and R. J. Carski of the Baltimore Biological Laboratory, Baltimore, who supplied the participating laboratories with Standard and T-G-E-M agar, and with A.A.M.M.C. agar, respectively, without charge.

The Care of Premature Infants*

ETHEL C. DUNHAM, M.D.

Director, Division of Research in Child Development, Children's Bureau, U. S. Department of Labor, Washington, D. C.

THE fate of the premature infant depends on a number of factors, among which are the health of the mother during pregnancy, the degree of the infant's immaturity at birth, and the care that is received by the infant after birth.

Methods of caring for premature infants have been determined largely on a trial-and-error basis rather than on a scientific one. The lack of adequate study and evaluation of such methods from the clinical and the experimental points of view has been due largely to the lack of realization of the magnitude of the problem and of the results that may be expected when increased efforts are made to reduce the mortality among premature infants.

It is true, of course, that infants weighing at birth less than 1,000 gm. (2.2 lb.) rarely survive. Since weight in itself is not an exact measure of maturity, this criterion should not be used alone to judge viability. Some obstetricians state that an infant weighing less than 1,500 gm. is "previsible." There are, however, a large enough number of records of the survival of infants weighing at birth less than 1,500 gm., and even less than 1,000, to warrant efforts to save such infants,

regardless of the size or maturity of the individual infant. Hoffman¹ and his coworkers have reported the case of a premature infant that lived, although it weighed at birth only 735 gm. (1.6 lb.). In Figure I this infant is shown at 23 days, and in Figure II, at 35 days. Figure III shows the initial loss in weight and the gain up to the age of 100 days. Figure IV shows the infant at 1 year, weighing 17 lb., 5 oz.†

Statements are found in the literature that when these small infants survive, a large proportion of them, even if they develop physically, show more or less mental retardation. These statements, however, have not as a rule been based on acceptable psychological tests, nor have satisfactory controls been used. That premature infants develop normally—both physically and mentally—as do full-term infants has now been well established through the work of Hess, Mohr, and Bartelme,² and of Gesell³ in the United States, as well as by that of von Sydow⁴ and Melcher⁵ in Europe, and a number of other investigators. For example, Hess, Mohr, and Bartelme² state: "... our comparisons of two groups of prematurely born children ... with full-term children ... indicate that premature birth unassociated with intracranial injury

FIGURE I—Premature infant 23 days old.
Birth weight, 735 gm.

does not affect mental development.” The conclusions of these specialists in the field of pediatrics and psychology have been well expressed by Gesell³ as follows: “Present data, though scanty and sometimes contradictory, indicate that prematurity of birth in itself does not markedly distort, hasten, or retard the course of mental development when the age of the infant is reckoned from conception.”

How many babies are born prematurely each year? As premature birth is not reportable throughout the United States Birth Registration Area, and as data in this regard are not compiled by the Bureau of the Census, the answer to this question is not known except on the basis of special studies. The Children's Bureau,⁶ in a study of nearly 23,000 live births occurring in 8 cities, found that 5 per cent were premature. A recent report by the Metro-

politan Life Insurance Company⁷ of a survey made in 13 leading hospitals in the United States showed that slightly more than 5 per cent of the 141,098 live births that occurred in these hospitals during the period 1933–1936 were premature. In New York State, exclusive of New York City, more than 4 per cent of the 82,000 infants born alive in 1936 were reported to be premature.⁸ In Chicago slightly more than 4 per cent of the 97,000 infants born alive in 1936 and 1937 were reported to be premature.⁹

There were in the United States 2,144,790 live births in 1936.¹⁰ If an estimate is made that 4 per cent of these live births were premature, more than 85,000 infants were born prematurely in that year. Such an estimate obviously does not take into account geographic or racial variations or the social and economic factors that have

FIGURE III—Initial loss and gain in weight.

been shown to influence the incidence of premature birth, but it is believed that this 85,000 is an underestimate rather than an overestimate of the number of infants born prematurely in the United States each year.

The mortality rates among premature infants under 1 month of age are high—between 15 and 16 deaths per 1,000 live births (in the period 1933–1936). In Figure V, which shows the causes of mortality in the first month of life, it can be seen that 81 per cent of the deaths are due to prenatal and natal causes. Almost half, 46 per cent, are due to premature birth.

In the 6 years, 1931–1936, there has been practically no decrease in the mortality rate from premature birth, and in the past 22 years a very slight decrease—from 17.7 in 1915 to 15.1 in 1936. In 1936, the latest year for which such information is available, there were in the United States 32,452

deaths in the first month of life that were reported as due to premature birth.

These mortality rates from census re-

CAUSES OF NEONATAL MORTALITY UNITED STATES, 1936

Children's Bureau

FIGURE V

ports do not permit the drawing of as accurate conclusions as would be possible if a standard for reporting an infant as premature had been used by the physicians who signed the death certificates. The consensus of opinion expressed in a resolution by the American Academy of Pediatrics,¹¹ is that all infants born alive who weigh at birth 2,500 gm. (5½ lb.) or less should be treated as premature regardless of period of gestation, crown-heel length, or any other criterion of prematurity. This is the same weight as that recommended as a criterion by the British College of Obstetricians and Gynaecologists.¹² Using this criterion of prematurity—a birth weight of 2,500 gm. or less—7 hospitals have made available to the Children's Bureau comparable reports on more than 4,000 premature infants. Since the mortality among premature infants is highest for those with comparatively low birth weights and lowest for those with comparatively high birth weights the infants reported on by each hospital were studied in four weight groups. In the group of infants in the highest weight group weighing

2,001 to 2,500 gm., in which the best results might be expected, the mortality in these 7 hospitals varied between 6 and 14 per cent; in the group weighing 1,501 to 2,000 gm., the mortality varied between 22 and 45 per cent; in the group weighing 1,000 to 1,500 gm., between 57 and 84 per cent; and in the lowest weight group (less than 1,000 gm.) between 85 and 100 per cent. In the 7 hospitals the total mortality among the premature infants varied between 20 and 34 per cent. From these variations in mortality it is apparent that the mortality among premature infants can be greatly lowered.

In connection with the data reported by the 7 hospitals to the Children's Bureau it should be pointed out that in these reports the infants in the two lower-weight groups constituted a relatively small proportion of all those weighing 2,500 gm. or less—4 and 11 per cent respectively—whereas those in the two higher-weight groups constituted 26 and 58 per cent of the whole group. That these proportions hold in a series of live births that include both mature and premature infants can be seen in Figure VI, in which nearly 2,800 infants born alive in New Haven Hospital, 1928–1932, are represented. Of all the infants weighing 2,500 gm.

or less, those in the lower-weight groups constituted 2.4 and 10 per cent respectively, and those in the two higher-weight groups 25 and 63 per cent respectively.

The advantage of a standard measure, such as a weight of 2,500 gm. ($5\frac{1}{2}$ lb.) or less, to apply when determining the need for special care of premature infants has been pointed out. When such a measure is used statistics can be compiled which make it possible to gauge the success of methods of care, to compare the results of these methods with those used by other workers, and to evaluate new methods of care.

In recent years considerable publicity has been given to the need for the reduction of mortality among premature infants. The Conference on Better Care for Mothers and Babies, held January, 1938, and the National Health Conference, held July, 1938, both stressed the need for reducing neonatal mortality, especially mortality among premature infants.

Thirty years ago three principles for the care of premature infants were enumerated by Rommel.¹³ These are: maintenance of body temperature, proper feeding, and protection from infection. Rommel emphasized the importance of applying warmth immediately after birth and of keeping the infant in a *warm* room. In discussing artificial warmth for the premature infant he named the following among the qualities required in an incubator: simplicity and sureness in operation; cleanliness; ventilation and moistened air (the humidity should be about 60 per cent); accurate regulation of the temperature at 79° to 82° F. He added, "We must admit unfortunately that despite the greatest care there is hardly an existing model which fulfils all these demands." Heated cribs, hot-water bottles, and so forth, were mentioned by Rommel in this connection, and the advantage of these, he stated, is that

the "breathing air" does not become heated.

For feeding, Rommel advocated mother's milk "above all things" and stressed the importance of calculating the amount of milk required by the infant so as to avoid overfeeding or underfeeding. The caloric requirement, he stated, varies "from 130-120-110 calories per kilo of body weight, diminishing with the increasing weight and age of the child." Feedings should be at 2 hour intervals or even shorter ones—10 to 20 feedings in 24 hours. Gavage, or else feeding by means of a pointed spoon, must be employed in feeding very small infants.

Rommel recognized infection as dangerous to the premature infant and stated that prevention may be accomplished most successfully by "skillful attendance." Among therapeutic measures he mentioned the use of oxygen and "injection of artificial serum (20-30 cc.)."

These principles of care, set forth 30 years ago, are still generally accepted as in the main correct but, unfortunately, are far from being generally applied.

What contributions to the knowledge of methods of care of premature infants have been made in recent years? Very little progress has been made, but some of the principles already mentioned, which were developed empirically or from clinical observations, have been established on a more or less scientific basis.

In applying the first principle of care of the premature infant, namely, regulation of the body heat, the air conditioned room has been developed, in which both temperature and humidity are controlled automatically. The old-fashioned incubator has been replaced by modern types of electrically heated beds, the temperature of which is regulated by thermostat. In such a bed the infant breathes the air of the room or

an air mixture that can be controlled. Simpler and less expensive types of heated beds or heated hoods to use on ordinary bassinets or beds have been developed; one of these heated hoods is shown in Figure VII. This is modeled on the type developed by Nobel, modifications of which have been described by Parmalee¹⁴ and by Livingston.¹⁵ In all these types the infant's head is outside of the heated bed and he is breathing the room air. For use in transporting the infant from the delivery room to the special nursery for premature infants, or from home to hospital, heated units have been used which cover the infant completely but allow for ventilation through windows, the size of which can be altered.

Hess and his coworkers¹⁶ have shown that by education of parents and physicians so that they send premature infants immediately after birth to a hospital, and by putting such infants in a portable heated bed for transportation to the hospital the mortality among such infants can be appreciably reduced.

Blackfan and Yaglou¹⁷ have studied in air conditioned nurseries the effect of varying temperature and humidity

relationships on the well-being of the premature infant, and conclude that a humidity of about 65 per cent and a temperature ranging from 75° to 100° F. constitute optimal conditions.

In regard to feeding premature infants, the consensus of opinion holds that breast milk is the safest food. Some authorities state that when small amounts of breast milk must be given, the milk should be fortified by the addition of carbohydrate.

In using artificial feeding it is, of course, important to consider certain peculiarities of the premature infant when compared with the mature infant. It has long been known that premature infants often show marked difficulty in fat absorption, and Tidwell and his coworkers¹⁸ have demonstrated that certain fats are better absorbed than others. It has long been known that the protein requirements of premature infants are high. Darrow and Cary¹⁹ have found the total proteins of the blood of premature infants to be low, chiefly because of its low globulin content.

The total caloric and fluid requirements of the premature infant must be accurately calculated. The metabolism

FIGURE VII

ELECTRICALLY HEATED HOOD TO BE USED ON PREMATURE BABY'S CRIB

of the premature infant was first studied by Benedict and Talbot.²⁰ Gordon and Levine,²¹ using a specially constructed chamber, have also studied the metabolism of premature infants and have made important recent contributions to the knowledge of the caloric and fluid requirements of these infants in relation to body weight and environmental temperature.

The tendency of the premature infant to develop anemia and the importance of beginning anti-anemic therapy shortly after birth have been demonstrated by Josephs²² and by Davidson and Merritt.²³ The work of Davidson, Merritt, and Chipman²⁴ also has confirmed the long recognized fact that the rapid growth of premature infants makes them prone to develop evidences of vitamin D deficiency, and has shown the importance of beginning effective preventive therapy early. Park²⁵ states that to prevent rickets in a premature infant "it may be necessary to give 1,000, 5,000, or 10,000 units, or for a time even more daily in the form of the highly concentrated fish-liver oils, viosterol in oil, or other vitamin D preparation." Goodwin²⁶ has pointed out that administration of cod liver oil to small, debilitated infants is often fraught with danger, as the swallowing reflex may be inactive and therefore the oil may be aspirated, whereupon lipoid cell pneumonia may result. In view of this danger it is wise to use a concentrated preparation of vitamin D of known potency in a non-oily mixture.

It has been suggested that the premature infant probably lacks certain hormones that are transmitted to the full-term infant through the placenta shortly before or during birth. Some hormones have been administered to such infants, but the benefits derived from them have not as yet been well established.

Bakwin²⁷ has shown that the cyanosis so commonly seen in premature infants

may be due to anoxemia, which can be relieved by the administration of oxygen. A supply of oxygen and proper apparatus for administering it to small infants should be readily available wherever a premature infant is being cared for.

The importance of preventing infection in premature infants has been stressed in efforts that have been made to establish standards for the care of premature infants in hospitals. Those established by Hess²⁸ in the premature unit of the Sarah Morris Hospital have been adopted by the Department of Health of the City of Chicago as part of a city-wide campaign to reduce mortality from premature birth. These include individual equipment for bathing and feeding the infants, proper arrangements for disposal of soiled diapers and linen, exclusion from duty of attendants and nurses with infections, wearing of gowns and masks and washing of hands by attendants, nurses, and physicians, running water readily accessible, and isolation of infected infants. In addition, a regulation of the Department of Health requires that the birth of a premature infant be reported within 24 hours after it occurs.

For transportation to the hospital the infant is placed in a heated portable "ambulance"; the hospitals in the city have been studied and graded according to the facilities afforded for special care of these infants and minimum requirements for hospital care have been set up. These include in addition to those already enumerated the provision of some type of heated bed, a supply of oxygen with necessary equipment for administering it, a thermometer and hygrometer in the infant's room, and—particularly important—provision of qualified nursing personnel. Notification of the board of health is required before the infant is discharged from a hospital. In addition to these requirements certain recommendations are

made, such as attendance of a pediatrician in the delivery room, prompt transfer from delivery room to special nursery, breast feeding, and separate room for care.

Standards for the care of premature infants in hospitals are at present under discussion by a committee on premature infants, appointed by the Commissioner of Health of New York City, and composed of representative pediatricians and obstetricians, the object being to reduce morbidity and mortality among premature infants.

With the same object in view the Division of Research in Child Development of the U. S. Children's Bureau is coöperating in studies of premature infants at New York Hospital. Metabolic studies are being made to determine the food and water requirements of these infants. In addition, a follow-up clinic is being developed at this hospital to improve home care and to obtain data in regard to social and economic as well as health factors affecting the welfare of these infants. The causes of premature birth will also be investigated. Knowledge of these causes is necessary in order to reduce the incidence of premature birth. This aspect of the problem has been greatly neglected.

These programs reflect the increasing interest in the problems of the reduction of mortality from premature birth, as do the most recent plans submitted by the maternal and child health divisions of the various states to the Children's Bureau for approval under the terms of the Social Security Act.

Eight of the 48 states, as well as the District of Columbia and the Territory of Hawaii, have some plan contemplated or already in operation for improving the care of premature infants. The most complete plan is that now being carried on by Massachusetts under the direction of a special division of the health department with a full-

time physician in charge. This program includes enactment of a law making premature birth reportable, establishment of hospital centers for the care of premature infants, and an educational program for physicians, nurses, and mothers. The preventive aspects of the problem are stressed by encouraging the establishment of prenatal centers in hospitals and communities.

The state health departments of New York, Tennessee, West Virginia, Colorado, and Nebraska have provided special warm beds for distribution; those of Wyoming, South Dakota, and Hawaii have planned to provide such beds. Special booklets on the care of the premature infant have been published by the divisions of child hygiene of the state health departments of Massachusetts and West Virginia, and by the U. S. Children's Bureau.

Successful reduction of morbidity and mortality among premature infants requires not only use of the most efficient methods now available for caring for such infants but also continued alertness to the need for the development of more efficient methods of care. Education of parents, nurses, and physicians in the special care of premature infants at home and in hospitals will without doubt save the lives of many premature infants.

Effectiveness of Different Systems of Collecting Vital Statistics Data*

J. V. DEPORTE, PH.D., F.A.P.H.A.

Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

WHILE the United States has the distinction of being the first country in the world to provide in its Constitution for a periodic enumeration of population, the general acceptance of the importance of recording births and deaths came about very slowly. It was only 5 years ago that a nationwide system of registration was finally achieved. When one considers that England has had accurate birth and death statistics for 100 and Sweden for almost 200 years, the impulse toward self-criticism is quite natural. It is important to realize, however, that in all logic, comparison should be made not with individual countries but with the entire continent of Europe, not only because of the magnitude of the area of the United States but the fact that it is composed of many autonomous units exhibiting wide geographical variations and important differences in historical tradition, customs, and economic conditions.

Some of the original states evinced as strong an interest in registration as any of the countries of the Old World. Chronologically, the first place in this field belongs to Virginia, which as early as 1632 enacted a law requiring

ministers and church wardens to report marriages, births, and deaths. And by the way, certain procedures set up by this law have remained unchanged for three centuries and were modified only a few years ago. A law similar to that of the colony of Virginia was passed by Connecticut in 1644, by Massachusetts Bay Colony in 1639, and New Plymouth in 1646. The "Fundamental Constitutions" prepared in 1669 for the government of Carolina by the Philosopher John Locke contained stringent provisions for "a Registry in every Seignior, Barony, and Colony, wherein shall be recorded all the births, marriages and deaths that shall happen." According to one writer, "Massachusetts was the first state in the Christian world which recorded births, deaths, and marriages by government officers," as such instead of baptisms, burials, and weddings. The first registration law of modern type was enacted in Massachusetts in 1842 as a direct consequence of the English law of 1837, which made statistics the foundation of modern sanitary progress.¹

In 1847 the United States National Medical Convention, meeting in Philadelphia, urged upon the various state governments "the adoption of measures for procuring the registration of births, marriages, and deaths occurring in their several populations." The Convention, pointing to the "ordinary

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

purposes for which such registration should be universally adopted, such as proofs of lineage, rights of dower, and bequests of property," considered the following as the more vital reasons:

First, upon the circumstances connected with the three important eras of existence, birth, marriage, and death, are dependent, to a large extent, the physical, moral, and civil condition of the human family.

Second, a knowledge of these circumstances is necessary for a full comprehension of important means for the certain advancement of the population of states, in prosperity and civilization.²

The example of Massachusetts was followed by other states but progress ceased when the Civil War and its social sequelae occupied the attention of the country to the exclusion of everything else. Agitation in favor of state registration was resumed in the last quarter of the 19th century, but as it was then observed by Dr. Cressy Wilbur, the completion of the task could not come about spontaneously for a long period of time. Dr. Wilbur placed the achievement of the goal as far ahead as the end of the 20th century. That this goal was reached much earlier than had been anticipated was in the main a result of the activities of the Bureau of the Census after its establishment in 1902 on a permanent basis and the energetic coöperation of interested professional and commercial organizations. Another factor, of perhaps equal importance, was the unforeseen growth of ways of communication.

In the history of registration in this country, three distinct stages are discernible. The first, when the formulation and enactment of legislation was largely a matter of local initiative; the second, during which the Bureau of the Census and various unofficial agencies actively concerned themselves with the development of local registration, furnishing advice, technical and, in many instances, financial assistance. We are

now in the third stage, which is in a sense a synthesis of the first two: satisfactory legislation laws have been enacted by all states, which are now directing their energies toward as near an approach as possible to the ideal of complete, timely, and accurate registration and the utilization of records for the public welfare, with the Bureau of the Census acting in an advisory and coördinating capacity.

The function of registration is exercised by the state departments of health with the single exception of Massachusetts, which places this duty upon the Secretary of the Commonwealth.

In order to make possible an intelligent discussion of the subject of this paper, all state registration officials were asked to reply to the following two questions: (1) How are the birth, death, marriage, and divorce records forwarded to the state office? (2) What, in your opinion, is the most satisfactory system for the collection of vital statistics data?

A summary of the comprehensive communications which my colleagues from 36 states were good enough to send me follows:

In 4 states all birth and death certificates are either filed with the county health officers, who transmit them to the state department, or are routed by the local registrars through the county health departments.

In 12 states the certificates are sent direct by the local registrars to the state departments. In one of these states the local registrars also send copies of the certificates to the county health officers.

Twenty states combine the two preceding methods: the certificates are forwarded by local registrars direct to the state department of health, except that in counties having health departments or in sections of states having full-time health units the certificates are sent to these departments or units

for transmission to the state department.

Central registration of marriages is provided for in 23, and central registration of divorces in 10 of the 36 states. In 3 states the state departments receive *copies* and not the original documents.

Birth and death records are forwarded to the central office once a month with the exception of one state, in which the birth records are forwarded once a year, and one other state which provides for the weekly forwarding of these records. The latter arrangement permits the nursing service of the state department of health to establish contact with a family in which there is a new baby within one or two weeks after delivery.

In most of the states, marriage and divorce records are forwarded to the state office once a month; in a few states the records are filed either quarterly or annually.

The views of the state registration officials on the most satisfactory method for the collection of vital statistics data may be grouped into three classes:

1. The original system, which provided that birth and death records should be forwarded by local registrars direct to the state office, has proved its worth and should not be tampered with.

This position is clearly presented by David South, State Registrar of New Jersey: "I am of the opinion that since the present system is so well established and appears so satisfactory, little would be gained by routing the certificates through county health departments. Surely such a procedure would result in a greater loss of records in transit and delay in the filing of records with the state office."

Gerda Pierson, Director of the Minnesota Division of Vital Statistics, is unequivocally opposed to the forwarding of records through a county health department because "Re-routing the returns would undoubtedly result in

delay in their reaching the Department." To meet an anticipated argument, she adds: "The county health officers are furnished much statistical data and other information they desire for their counties by the Division of Vital Statistics, and they have means of securing any special information they may desire in a hurry from the local registrars or other source in the county."

2. The efficient functioning of state registration requires the abolition of local districts in favor of larger units, preferably on a county basis.

Dr. Maysil M. Williams, State Health Officer of North Dakota, is an eloquent advocate of this proposal:

Small registration districts were necessary in the early days, but with the universal use of automobiles and efficient postal service the distance between local registrars could be increased without jeopardizing the efficiency of registration. A physician's practice in rural areas extends for 15 or more miles into surrounding territory. This necessitates knowledge of many local registrars who are changing annually . . . Personal contact and instruction by the State Registrar is impossible due to the large number. Consideration is being given a plan in which there would be one local registrar in each county, with sub-registrars where needed for the purpose of issuing burial and removal permits.

In Nevada, says Dr. John E. Worden, Health Officer of that state, the small population is scattered over such a large area that the county system "is the only practical method," local registrars being retained in a few of the isolated places where there is no local physician.

3. Local registration districts should be retained but in counties having full-time health departments the birth and death records should be routed through these departments.

Dr. W. J. V. Deacon, Director of the Michigan Bureau of Records and Statistics, considers this "the ideal system of registration."

In New Mexico, according to Miss Billy Tober, State Registrar, "The

intermediary stage is essential for the proper operation of county health work." Besides, "progress (in the registration of births and deaths) would not have been made if the personnel in the county health departments . . . had not spent some time on registration work."

Dr. Franklin H. Reeder, State Registrar of West Virginia, finds that the routing of certificates through a county health department "is not only a service to the county health officer, but by keeping his interest in registration alive it often makes him a valuable ally."

In my opinion, the weight of the argument is definitely in favor of the third point of view. Those state registrars who oppose the routing of certificates through county health departments or district state health offices base their opposition on the possible risk of loss of records in transit and delay in the receipt of certificates in the central office. However, if local registrars continue to report to the state office the *number* of births and deaths recorded with them each month and if the county or district office functions properly, the risk of loss of certificates cannot be considered a serious matter. The delay in filing the certificates with the central office need not exceed a few days—sufficient to allow the county or district office to copy and to forward the certificates to the state department of health.

Basic to the entire discussion is the question: Can a county health department or district state health office function efficiently without immediate knowledge of the occurrence of births and deaths in the territory under its jurisdiction? I am not an expert in local health administration, but even superficial acquaintance with it obliges me to reply in the negative. Several registrars have stated that a county health department can secure the neces-

sary statistical guidance from the state office or, if pressed for time, can get the information it desires from the offices of the local registrars. I doubt if a county or district health office could do its best work on a diet of canned statistical food. A complete statistical table prepared in keeping with all rules of statistical practice is one thing, while first-hand acquaintance with the original birth and death certificates is an altogether different matter. The day by day picture of developments in the county or district which a health office needs for proper functioning cannot be supplied even by the most elaborate monthly reports compiled by the state office. As for visits to local registrars, it would be clearly impossible for the county staff to undertake them with the necessary frequency.

In considering the situation in the country as a whole, one is led to the conclusion that here, as in many other elements of our national life, there is no single system that will best serve the needs of the people of all states. In a state like Nevada, with 0.8 person per square mile, efficient registration can be achieved, perhaps, only through the substitution of county for local registrars; while in Delaware, for example, where the density of population is 102 persons per square mile, and where according to Dr. A. C. Jost, State Registrar, even the farthest removed local registrar is within an hour's drive from the state office, registration on a county basis would be nonsensical.

The difficulties of devising a uniform system have been clearly depicted by Dr. W. W. Hubbard, Director of the Tennessee Division of Vital Statistics:

The state is divided into three distinct geographic areas, each having different population and racial distributions, different natural barriers, and a varying distribution of medical facilities, such as hospitals, physicians, etc. Many states have similar prob-

lems. There is probably no uniform system that could be used satisfactorily in all localities . . . It seems desirable to fit the collection system to general area problems. In some communities, it seems best to put all collection into the hands of local health departments, and eliminate intermediate handling by registrars. In some rural areas a local registrar for each minor civil district is imperative. In other counties, consolidation of registration districts is proving effective.

My own belief is that unless conditions make it impossible, the framework of a state registration system should consist of local registration districts, county and district state health offices being used as intermediary stages, *provided these offices have adequate equipment and personnel*. For this reason, the necessary legislative provision should be made optional and not mandatory. In New York State, for example, the desirability of introducing the intermediary stage and its continuance is in each individual instance governed by the judgment of the state commissioner of health. At present this system is effective in all of the 6 counties which have a full-time health department and in 1 state health district comprising 2 counties. The system will be extended to the other health

districts when in the opinion of the state commissioner of health they are able to undertake this function.

It may be advantageous at times to consolidate two or more local districts; such consolidations, however, should be made only after a study of local conditions. There is no need for having separate registration districts in a village and a town if, as it often happens, the town registrar is also town clerk and the town hall is located in the village. On the other hand—to recall a recent case—consolidation would be definitely against the public convenience if the township were cut in two by a mountain range which is barely passable in inclement weather. The merits of one or another system must be weighed in terms of our basic objective—complete, timely, and accurate registration of all births and deaths. Short-cuts may be considered only if they do not endanger this aim.

DISCUSSION

R. N. WHITFIELD, M.D.

Director of Vital Statistics, State Board of Health, Jackson, Miss.

I VERY cordially agree with the idea that birth and death records should pass through the hands of the full-time county health office before reaching the central office of the State Department of Health.

It has been my observation that health officers ten or twelve years ago minimized the importance of vital statistics records in their counties, and,

in fact, at that time I could secure very little coöperation from these officials in my efforts to obtain as near 100 per cent registration as could possibly be done.

The health officer was fully alert to other duties such as school examinations, vaccinations, and public health education in general, but it seems that he considered vital statistics of very

minor importance in his program, not realizing, of course, the leading position which these statistics should have occupied in planning his various and sundry public health endeavors.

In recent years, however, it has been noted that the health officer not only realizes his need for vital statistics, but is keenly alive to any suggestion which may be made to him for obtaining a full and complete report of every birth and death occurring in his territory. Also, they are asking and demanding that we place in their hands the birth and death certificates of their sundry counties before such records are forwarded to the central office.

Our health officers are not only making immediate use of these statistics for guides in public health work, but they are keeping card records of births and deaths in their files from year to year.

It adds very much to the prestige of the county health department to be able to give information locally, especially to school authorities with reference to ages of children first entering school. Also, this ability to show the information needed relieves the central office of a great deal of searching among the records for identical purposes.

It seems reasonable to me that since conditions have changed to such a remarkable extent within the past 25 years, every state should seriously consider the proposition of whether or not its methods of gathering birth and death certificates have changed with the times. In the year 1912, when our State Department was first organized, there were scarcely any automobiles, no good roads, the doctors were scattered throughout the rural communities, and home-made coffins were used in a large percentage of burials throughout the rural areas of our state. Undertakers were, of course, operating within the larger towns, but very few

of them attended to funerals at a greater distance than 12 miles away from their places of business.

At this time we can travel almost anywhere in the State of Mississippi in any sort of weather, and although we have been somewhat behind with building fine highways, we are now spending millions of dollars in the construction of modern roads. The doctors, as a rule, have congregated in the towns, the undertakers travel sometimes as far as 200 miles to bury the dead, and it does seem to me that we have no reason to cling to antiquated methods of filing birth and death certificates. Therefore, we now have barely more than 100 registrars of vital statistics in Mississippi, whereas, 10 or 15 years ago, we had over 1,000. In order to make smoother the operations of the county registrar, it was necessary to abolish the burial permit in all communities of less than 5,000 population. Of course, we require a transit permit for all bodies shipped out of Mississippi into other states.

As I have stated heretofore in these meetings, it is no more logical to require an undertaker to obtain a burial permit, than it is to force a physician to get a permit to attend a birth. No one seems to argue any other motive for the burial permit than to make, or attempt to make, more certain the filing of the death certificate. Our experiences in Mississippi show that the undertaker will come just as near filing the death certificate without obtaining a burial permit as he did when he had to obtain one, and, to tell the truth, his death certificate is more accurate when given a little time for its completion than it was when he had to get it ready to trade in for a burial permit before the body was disposed of.

However, I am ready to grant that in some states it is easier for an undertaker to prepare a death certificate and

obtain a permit before disposition of the body than it is in a state with a great deal of rural territory.

From what I have learned so far, several southern states have made much headway in consolidating registration

areas. It seems they are not eliminating the burial permit, but the methods they prescribe for such permits seem to me to be rather crude, and constitute ample proof that this formality is unnecessary.

The Nine Plank Platform of Andriya Stampar

DR. Andriya Stampar, of Yugoslavia, one of the great contemporary public health administrators, is visiting this country this summer. His own summary of his views on public health is reproduced below¹:

- (1) The education of the people is more important than laws, and for this reason our work (in Yugoslavia) is based upon three small laws only.
- (2) It is most important to prepare a correct attitude of society towards questions of public health.
- (3) The question of public health and of the work done for its advancement is not a monopoly of the doctors; but everyone, without distinction, should take part in it. It is only by means of this universal coöperation that public health can improve.
- (4) A doctor should be mainly a social worker; he cannot go far with individual therapy alone—social therapy provides the means that can lead him to real achievement.
- (5) A doctor should not be economically dependent on his patients because such de-

pendence hinders him in the most fundamental of his tasks.

- (6) In respect to public health no distinction should be made between the rich and the poor.
- (7) It is necessary to create a health organization in which the doctor shall seek out the patient, and not the patient the doctor, for it is only by so doing that the ever-increasing numbers of those whose health we should protect can be included in our care.
- (8) A doctor should be a teacher of the people.
- (9) The question of public health has more of an economic than a humanitarian significance. The chief place for a doctor's work is in the dwellings of the people—the places where men live and work—and not in laboratories or in a doctor's consulting-rooms.

The story of Doctor Stampar and his career as chief of the Department of Public Hygiene in the Ministry of Social Institutions of Yugoslavia is told by Louis Adamic, in Chapter XVI, *The Native's Return* (New York: Harper & Bros., 1934).—New York State *Health News*, July 3, 1939.

Infection of Air*

Bacteriologic and Epidemiologic Factors

W. F. WELLS, M. W. WELLS, AND STUART MUDD, M.D.

Laboratories for the Study of Air-borne Infection, University of Pennsylvania School of Medicine, Philadelphia, Pa.

CONCENTRATION of microorganisms in air (the number dispersed in unit volume) implies some degree of confinement. The potential hazard of infection from the air breathed in the semi-confined spaces of our habitations may be represented for any moment in time by the equilibrium between the addition rate of microorganisms and the rate of their elimination. A bacteriologic technic for the measurement of sanitary ventilation, inversely determining confinement, has been previously described.¹ The rate (K) at which bacteria suspended in semi-confined atmospheres are vented or killed may be determined directly, and changes in ventilation rates may be computed from the formula $P=C/K$ where the equilibrium (P) is measured and the rate of addition (C) of bacteria is maintained constant.

CONFINEMENT OF AIR-BORNE MICROORGANISMS

If air displacement alone in ventilated rooms is to be measured, no advantages are claimed for bacteriologic

procedures over gasometric methods.[†] In measuring infection and disinfection of air, however, the bacteriologic procedure offers a means of interpreting biologic ventilation in terms of air replacement. The rate at which viable microorganisms disappear from a semi-enclosed atmosphere through physical, chemical, or biological means can be expressed as equivalent ventilation (based upon air replacement).

The importance of distinguishing between the hygienic potentialities of bacterial ventilation by air displacement and by other means of disinfecting habited atmospheres has become evident from analysis of some 1,750 air samples, collected in studies on sanitary ventilation to be reported later. During the winter months, associated

† The equilibrium formula applies equally well if CO₂ is added to a room at a known constant rate (C). Let the rate of addition of CO₂ per person per hour (C) be 0.5 cu. ft.² With an air space of 200 cu. ft. per person,³ the addition rate (C) = $0.5/200 = 0.0025$ volumes per hour. With an air replacement of 1,200 cu. ft. per person per hour,³ the removal rate (K) = $1,200/200$ or 6 overturns per hour. The equilibrium (C/K) will be $0.0025/6$ or 4.2 volumes of CO₂ per 10,000 volumes of air. With an outside concentration of between 3 and 4 volumes per 10,000 the inside concentration would lie between 7 and 8 volumes. "Pettenkofer, in 1858, proposed 10 volumes of carbon dioxide in 10,000 volumes of air as a limit for inhabited rooms. DeChaumont (1875) found that an unpleasant odor became perceptible in air containing 6 volumes of carbon dioxide in 10,000, and fixed this as a limit, which for many years was accepted by sanitarians."²

* This study is supported by a grant from the Commonwealth Fund to the University of Pennsylvania for investigations on air-borne infection, with laboratories in the Department of Bacteriology, the Children's Hospital of Philadelphia, and the Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis.

with the spread of respiratory infections, when the closing of doors, windows, or other natural vents confines the air commonly breathed by many persons, natural ventilation rates fall below 10 overturns per hour. To double air replacements, during cold weather, by mechanical or window ventilation raises practical difficulties, and has led to no conspicuous decline in respiratory diseases. With the opening of windows in the spring such infections consistently decline, with ventilation rates approaching 100 overturns per hour. Whether equivalent bacterial ventilation by air disinfection during the winter can accomplish similar hygienic results is an important problem in sanitary science.

An example of the solution of a general problem of sanitary ventilation by means of air disinfection, through experimental methods applying the bacteriologic procedure, is provided in the study and design of isolation cubicles in which ultra-violet light screens replace solid partitions or in which there is dropped a curtain of light continuous with an irradiated reservoir or "ceiling" above the eye level into which any solid cubicle partitions project.⁴ Such cubicles, the experimental units of which were built and tested in the Henry Phipps Institute, Philadelphia, are now in routine use in the new building of the Cradle Society, Evanston, Ill. (Figure I). Sanitary ventilation tests upon the bacterial tightness of the experimental cubicles indicated: (1) in Type A cubicles (i.e., with solid partitions between cubicles, ultra-violet light curtains between cubicles and corridor), 99.6 per cent of the test organisms were removed in passing from the corridor to the cubicle, 98.9 per cent in passing from the cubicle to the corridor; (2) in Type B cubicles (i.e., where partitions between cubicles also were replaced with a curtain of ultra-violet light), 99.7 per cent of the test organisms were

removed in passing from cubicle to cubicle. Tests upon the cubicles in the completed building, under actual operating conditions, have exceeded the results in the experimental unit.

Trial installations of light barriers have also been designed for the Children's Hospital, Philadelphia, and the Infants' and Children's Hospital, Boston, and such cubicle isolation would seem generally applicable to hospital use.

BACTERIOLOGIC FACTORS

Methods—The equilibrium between the infection rate and the ventilation rate of the air of our habitations varies with a multitude of factors such as season, weather, variations in activity from day to day, hour to hour, or even minute to minute. The statistical constants which define these variable characteristics depend upon the analysis of numerous samples and, since air is a rarefied medium, upon large volumes. Examination of so changeable a medium requires an instrument adaptable to extensive field service. Simplicity and directness in technic are practical prerequisites both of economy and accuracy in any widespread sanitary survey.

It goes without saying that a method must be determinate, that with each condition a definite result is obtained, and that these results under uniform conditions are reproducible within the normal variation of the conditions themselves. It is a matter of convenience that the results be quantitatively proportionate to variations in conditions, or bear some simple functional relationship. "Absolute bacterial densities" are mere abstractions useful only in interpretation, and never delivered by bacteriologic technics.⁵

The numbers and kinds of organisms recovered from an air sample also depend upon the conditions of culture. An instrument must be flexible enough to permit the use of various culture

media. Direct collection on the culture medium may be desirable with sensitive parasitic organisms which quickly perish in the air. Organisms growing readily at blood temperature have been found in sanitary water analysis to be more indicative of pollution than those growing at room temperature, and the same principle holds in sanitary air analysis.⁵ Whereas intestinal organisms are of primary concern in drinking water, nasopharyngeal organisms have significance in the air we breathe. Whereas gas formation in lactose broth is characteristic of intestinal contamination, green-producing streptococci (on blood agar) typify nasopharyngeal contamination. While special technic may be required in the search for pathogens or in special problems, the most serviceable method for general sanitary air analysis uses blood agar incubated at body temperature.

Results—Results of some two thousand air samples collected and analyzed by the Wells technic⁶ are summarized in Table I. About one-third of these samples were analyzed in the authors' laboratories, with the assistance of several collaborators acknowledged in reporting the various studies. The remaining two-thirds of the samples were collected by the WPA Air Pollution Survey of the Department of Health of New York City,⁷ and are indicated in the table by a dagger.

The textile mill samples represent atmospheres during a period of economic depression rather than the busy activity of better times. The average count given for Mental Hospital A does not give a complete picture for it averages the highest counts obtained under actual living conditions with lower counts which obscure this fact. The high streptococcus counts, however, may reflect the dissemination of respiratory organisms associated with the epidemic of pneumonia during which the samples were taken. The theater tests

may also seem unnaturally low, and in the case of the Boston results we know the samples were taken between the warm and cold weather when the ventilating system was operating at its full capacity to exhaust the heat generated within the theater. In the results of subway samples as reported, there is nothing to indicate the jam during rush hours, nor does the report specify the conditions under which the samples were taken.

No pretense of precision can, therefore, be implied in this summary because standardization of collection and of isolation technics has not yet been perfected. Blurring due to imperfect technic may account for the want of contrast between some of the categories as compared to the clear definition observed among other categories. Want of technical skill in many of these laboratory analyses cannot be denied, any more than can perfect analysis compensate the failure of collections to represent truly their assumed classification—a more serious matter.

SANITARY INTERPRETATION

In spite of these imperfections, however, the categories exhibit significant differences which serve the primary purpose of this paper. The difference between the counts of indoor and outdoor air is outstanding. Most samples classed as "indoor air" were taken during the colder months when "indoor air" was "confined air." The mill samples, though collected during the summer, represent air confined in order to regulate the humidity.

Exclusion of Polluted Atmospheres—Particularly in hospitals, where pathogenic sources are known to exist; may high total count signify increased hazard of infection. The provision of independent air supplies in special wards or rooms (as the premature ward of the Infants' Hospital in Boston)^{8, 9} where asepsis is a vital consideration

TABLE I

Sanitary Analyses of Air Supplies of Various Human Aggregations

	Number of Samples	Average Number of Colonies per Sample *	
		Total	Alpha Streptococci
<i>Outdoor Air</i>			
Boston, Longwood	72	16	0.12
Philadelphia, downtown	23	50	0.0
New York, streets †	143	112	0.45

* The samples were approximately 10 cu. ft., but the accuracy of sampling and isolation by various workers does not warrant more precise analysis

† These figures are computed from Pincus and Stern, *A.J.P.H.*, 27:321, 1937.

can be justified by the bacterial purity indicated by the tests. A study of the sanitary ventilation of Chapple infant incubators¹⁰ supplied with clean outside air clearly shows the sanitary superiority of the air within the incubators over that of the wards in which they were placed.

Qualitative Differentiation by State of Suspension—Interpreted in conjunction with other observations much valuable information upon the quality of the contamination may sometimes be derived from bacterial counts. In the study of textile mill atmospheres¹¹ the ratio of bacterial concentration as determined by the centrifuge to plate settling count proved of great value in distinguishing between bacterial contamination derived from dusty operations and that contributed by humidification with polluted water. The differentiation of contamination derived from such widely different sources is necessary to a proper hygienic evaluation of the bacterial content of the atmospheres.

Settling and Sedimentation—Quite apart from such qualitative sanitary distinction the settling rate of bacteria-laden particles as determined by the ratio of plate count to that obtained by the centrifuge provides the key for interpreting the flight range of air-borne infection in space and time. Sedimentation in still rooms is an important factor in removing dust from the air.¹² The accumulation of settled infected dust¹³ may, however, provide a dangerous source of reinfection. In operating rooms, preparations just preceding an operation may stir up accumulations, deposited over a long quiescent period between use and concentrate infection from distant parts of a hospital.

Particle Size and Purification—The coefficient of fineness, derivable from settling velocity,¹¹ may be a factor in the efficiency of purification devices which depends upon the physical char-

acteristics of the particles. Such distinction between bacteria introduced into air by evaporation of salivary droplets and bacteria raised as dust by processes of attrition may be of vital importance in the hygienic interpretation of bacterial tubes. This is well illustrated in efficiency tests of a railway car installation of ultra-violet lights which showed a much higher effectiveness against nasopharyngeal organisms than against the wild varieties enclosed in dust raised by activity within the car.

INDICES OF NASOPHARYNGEAL CONTAMINATION

The hygienic significance of breathing microorganisms fresh from the respiratory passages of others cannot be ignored. The numbers of streptococci characteristic of the nasopharynx indicate a hazard of respiratory infection and have a sanitary significance comparable with the presence of *Escherichia coli* in drinking water.¹⁴ Examination of averages in Table I shows how these numbers vary with the condition of occupancy.

Specific Infectivity—Fluctuations dependent upon sneezing are indicated in experiments from which it is estimated that several thousand nasopharyngeal streptococci per sneeze are contributed to the atmosphere. The sneeze thus almost seems to be a provision of nature for the survival of nasopharyngeal parasites. Even where the manifestations of a disease do not provide for the wide auto-dissemination of the infection through air it has been observed that an outbreak of colds will be followed by the rapid spread of contagion.^{15, 30} Sneezing induced by pollens might conceivably facilitate the spread of nasopharyngeal infection, and has indeed been suggested as a means by which the unseasonable spread of poliomyelitis is aided.¹⁶

These experimental results are borne

out by the field observations of Huddleston and Hull¹⁷:

During February, 1919, there existed in the Army of Occupation what amounted to an epidemic of severe "colds" with extremely bad coughs and sore throats. Pneumonia cases were numerous. The first experiment was conducted on February 23. . . .

It will be seen that in one minute an average of 82 organisms settled on the plates, and in five minutes, 151 organisms. . . .

In picking colonies indiscriminately from the incubated plates four type IV pneumococci were found, and many hemolytic and non-hemolytic streptococci, with numerous staphylococci and Gram-negative and Gram-positive diplococci. . . .

Eight days later (March 3), the experiment was repeated. . . .

By the first of March the epidemic had practically cleared up. . . .

The details of operation were identical in every particular—the same medium being used and the same methods. On the plates exposed 1 minute and 5 minutes the organisms found were extremely few in number. On the plates exposed 10 minutes an average of 16 colonies was counted. Among these, molds and staphylococci predominated; no pneumococci were found; 16 per cent of the total number of colonies present were streptococci, which showed partial but not complete hemolysis (alpha type).

This great reduction from 82 organisms in 1 minute to 16 organisms in 10 minutes, which settled on the plates directly corresponded to the falling off of the epidemic. In either case, however, a man sitting through a performance of 1½ to 2 hours would inhale enough pathogenic organisms to give him any respiratory disease which might prevail among those sitting about him, provided he did not possess some natural or acquired resistance.

The prevailing organism present in the respiratory passages of men admitted to the hospital at this time was *Streptococcus hemolyticus*.

Sanitary Indices of Pollution Load

—The impression gained from inspection of Table I that the numbers of alpha streptococci in the atmospheres we breathe conform in a general way to the density of occupation and the degree of air confinement, is strengthened by a more detailed analysis of the New York figures.¹⁸ Thus in reporting on

the 6 schools selected in the New York study, the authors state:

Schools numbers 1 to 3 have higher average numbers of streptococci per cu. ft. of air for all samples and for positive samples, as well as a greater percentage of positive samples, than do schools 4 to 6.

Schools 1 and 2 are two of the oldest in the city and are in the lower east side. They are of definitely inferior construction, contain small rooms, and are difficult to keep clean, number 1 being the poorer of the two. It may also be of interest that the children are of the lowest economic group in the city, and come from a health area which shows a high incidence of reportable communicable disease. Schools 5 and 6, the two high schools in the group, are located in the upper middle west side. While of more modern construction than the first two schools they cannot be called new. They are of more suitable design than the former, however, since they have large rooms, large windows, and high ceilings.

With respect to degree of occupancy they state:

The values for the average number of streptococci per positive sample for all schools indicate that occupied assembly rooms had most alpha streptococci, followed by occupied classrooms, corridors, just vacated classrooms, vacant assembly rooms, and vacant classrooms in the order named.

Table II likewise shows a relationship between passenger load of a railway car and the numbers of alpha streptococci present in the air. The ratio of streptococci count to passenger load for every moment in time obviously is not constant, but varies with activity of the passengers contributing to the atmosphere.

Hygienic interpretation of these results in the absence of extensive epidemiologic correlation can be based only upon general sanitary principles gained primarily from long experience with water supplies. The ingestion of intestinal organisms indicated by the presence of *Escherichia coli* in one-tenth of the volume of water consumed per 24 hours per person approximates a limit of safety set by the U. S. Treasury

TABLE II

*Relation Between Passenger Load and Bacterial Content of Air of Railway Car
(With and without ultra-violet light in air-conditioner)*

Ultra-Violet Lights Off

<i>Tube Number</i>	<i>Sampling Time (in Minutes)</i>	<i>Number of Passengers</i>	<i>Total Bacteria</i>	<i>Alpha Streptococci</i>

Standard¹⁹ for drinking water. The inhalation of more than 10 times as many respiratory organisms in the same period is indicated by the presence of three alpha streptococci per sample of 10 cu. ft.

EPIDEMIOLOGIC FACTORS

Sound sanitary principles appropriate to ingested infection from drinking water cannot be applied arbitrarily to an inhalation theory of the spread of respiratory disease without confirmation of the underlying assumptions. They may, however, lead to more fruitful hypotheses than the smug logic familiar to the early advocates of pure water that the air breathed "all one's life" cannot help to explain the universality of respiratory infection. Where the

droplet theory has led only to a hopeless attitude toward the sanitary control of respiratory disease, a theory of airborne infection, based upon the wide dissemination of *droplet nuclei* through occupied spaces,²⁰ promises such sanitary methods for building up community resistance against the spread of this important class of infections as have proved so successful in controlling spread of insect-borne and intestinal disease.

Topley and Wilson²¹ clearly indicate the potentialities of increasing community resistance by control of the sanitary factors involved in the spread of infection.

The herd, like each of its members, has a characteristic structure; and this structure, from our present point of view, includes

not only the hosts belonging to the herd species, and their spatial relationships to one another, but the presence and distribution of alternative animal hosts and possible insect vectors of infection, as well as all those environmental factors that favour or inhibit the spread of infection from host to host. This herd structure, apart altogether from the susceptibility or resistance of the individual hosts, may play a decisive part in the immunity of the herd as such. A herd may be immune to a particular disease—in the logical sense that it will resist the introduction of infection from without—although each of its members is fully susceptible, and would fall an easy victim if he strayed to a herd with a structure that allowed an endemic prevalence of the disease in question. In this sense the English herd is immune to plague; because the association of man, the rat and the flea is not now of a kind to allow spread along natural routes. It is probably immune to cholera, as the result of an adequate system of water purification. It is not—nor does it seem likely to become—immune to any of those diseases that are spread by droplet infection. It would take us altogether beyond our present scope to consider the known or problematical effects on herd resistance of such changes in environmental conditions; but we may at least note that many of the most striking successes of preventive medicine have been attained by altering herd structure without inducing any increased resistance in its individual members. By attacking insect vectors of infection, such as the mosquito, by preventing the frequent passage of bacteria from one person's intestine to another person's mouth by way of water and food, and by a general improvement in environmental conditions, we have succeeded in eliminating, or reducing to negligible proportions, diseases that formerly took a heavy toll of lives, and still take that toll in areas where such measures are not applied.

Substitution of the words "community resistance" for "herd immunity" would better contrast sanitary resistance to the spread of infection through a community with that conferred upon a herd by the specific immunization of a portion of its members.

If bacteriologic interpretations are corroborated by epidemiologic experience, sanitary ventilation, based upon a theory of air-borne infection by drop-

let nuclei, promises to become an important factor in public health.

SPREAD OF INFECTION THROUGH AGGREGATIONS

The hypothesis that contagion may be spread through the common occupancy of semi-confined atmospheres defines an epidemiologic pattern in terms of sanitary ventilation. Though sanitary and epidemiologic indices of ventilation have never been specifically correlated, extensive data on the spread of respiratory infection through various human aggregations sharing common atmospheres have accumulated. General correlation between types of ventilation characterizing these types of aggregation and epidemiologic indices derived from these studies reveals the consistency between our interpretation of the bacteriologic measure of air infection and the spread of respiratory disease.

Continuous Aggregations—The spread of disease through semi-confined atmospheres is not always an obvious phenomenon. Since the individual normally shuttles from aggregation to aggregation, it is generally impossible to distinguish the atmosphere within which an infection is contracted. Even where respiratory infections are known to be contracted within a continuous aggregation of individuals, only under special circumstances can sources other than air be entirely eliminated. In a careful study of the spread of infection in the Infants' Hospital, Boston, McKhann and his associates²² report 134 acute respiratory infections developing among 1,455 admissions during 1935 and 1936. Converted on the basis of the time of residence, this attack rate becomes an annual rate corresponding to *epidemic* spread of water-borne intestinal infection (more than 100,000 cases per annum per 100,000 population at risk). In a further analysis of these data,⁹ they conclude that contact infection,

droplet infection, and droplet nuclei infection are all operative within the hospital, and that a clear distinction must be made in the proportion of infections attributable to each mode of spread in an appraisal of methods of control. He distinguishes the principles of control applicable to each mode of spread, and will later report upon experimental control measures. He is extending to cubicle isolation the principle of an ultra-violet light barrier against droplet nuclei infection, inaugurated nearly 2 years ago in a corridor. He also remarks upon the striking reduction of respiratory infections in the premature ward,⁸ correlative with a demonstrated reduction in bacterial contamination, consequent upon the installation of an independent outside air supply (see Table I).

By means of the newer laboratory technics which permit cross-infections to be traced as both clinical cases and subclinical infections, we are coming to realize how much more numerous they are than had been supposed. Clinical cases of certain nasopharyngeal infections may constitute, according to advanced work, particularly in England, mere outcroppings of epidemic strata of subclinical infection which can be located by the newer technics of bacterial typing.²³ By such procedures the latent image of the mode of spread of nasopharyngeal infection, manifest in such diseases as measles and influenza and deducible from epidemiologic studies of age incidence and immunity tests,²⁴ may be developed.

Intermittent Aggregations — The spread of infection through intermittent aggregations may often be traced by the characteristics of the disease. The incubation period in some of the common infectious diseases of childhood, where lasting immunity is conferred, links primary with secondary cases. Every "contagious" case is secondary in some one aggregation, though it may or may

not be a primary to other cases in that or other aggregations. The number of secondaries thus exceeds the number of primaries except in the limiting case of perfect endemicity where the number of secondaries equals the number of primaries and there is no change in the rate of incidence. The sharper the epidemic, the more do secondaries exceed the primaries.

The spread of contagion through various types of aggregations describes the progress of an epidemic through the community. It is evident from Wilson's intensive study²⁵ of the epidemiology of measles in Providence that the 6 to 7 year old group of children provides the stratum of the population in which lies the reservoir of measles from which family primaries are drawn. This is true whether a younger or an older child is the primary in the family. Thus an elder child passing through this stratum without becoming a family primary is more likely to become later a secondary to a younger primary drawn from this stratum. The ratios of secondaries to primaries in the aggregations constituting this reservoir may vary independently from the ratios of secondaries to primaries in the family aggregations. Epidemic surges, therefore, arise from the interlocking of these various aggregations forming the knots in the vast network of contagion.

The family has been a favorite aggregation for the study of these phenomena:

One of the most characteristic features in the epidemiology of the common acute communicable diseases is the grouping of cases in time and space; and this is especially apt to be noted in the group which constitutes a household, people in close contact with each other, sharing a common environment, mostly of close kinship, and usually under the eye of at least one medical or lay observer whose observation encompasses the whole group.

Thus did Frost²⁶ introduce a discussion of "Familial Aggregations of In-

fectious Diseases" based upon Chapin's classic work on secondary attack rates. In 1925 Chapin showed that 88.3 per cent of presumably susceptible children of ages 1 to 5 contracted measles when a case was introduced into the home.²⁷ He concluded further:

Scarlet fever, consequently, is in reality much more contagious than the diagram would indicate, for the number of non-immunes is less than formerly assumed. It therefore seems probable that the greater contagiousness of measles, as suggested by Diagram III, is to a considerable extent apparent only. . . . Indeed, it is possible that diphtheria might be proved to be not so very much less contagious than measles. . . . We have no data in Providence bearing on the contagiousness of smallpox, but certain facts, from other places indicate that it approaches measles in this respect.

Dyer²⁸ quotes Rist and Weiss and Zingher and others who—

have noted the tendency of children of the same family to give similar reactions to the Schick test, and that in case of variations, as a rule, the younger children have shown positive reactions and the older negative, the reverse of this being very rare.

In response to the Dick test, Dyer's own results among 263 families of two or more children showed that: (1) in 151 instances all were Dick positive; (2) in 30 instances all were Dick negative; (3) in 41 instances younger children were positive, older were negative; (4) in 25 instances younger children were negative and older children were positive; (5) in 16 instances in family groups of three or more children, other combinations were shown. That is to say, in only 15 per cent of the 263 families was a younger child immune and an older child susceptible.

Similar phenomena with respect to tuberculosis among families is reported by Opie and McPhedran²⁹:

When latent tuberculosis is taken into consideration, tuberculosis exhibits the characters of a contagious disease and affects all children of households within which some member, suffering with tuberculosis, scatters tubercle bacilli.

As regards the spread of homologous types of pneumococci among family contacts, the Advisory Committee on Prevention of Pneumonia Mortality state³⁰:

The findings obtained in a few studies of a small number of families suggest that when pneumonia due to one of the more virulent types, for instance Type I, occurs in an individual, about 20 per cent of the other members of the patient's family are also carrying that same type of organism in their noses or throats. Where acute upper respiratory infections, such as colds, are prevalent among the family contacts, the incidence of homologous type carriers may approach 70 or 80 per cent.

The interesting epidemiologic fact³¹ that the average age at which first-born children contract clinical poliomyelitis is greater than second-born, second-born greater than third, etc., suggests simultaneity of infection, clinical or subclinical, within the family. The family pattern of subclinical infection would, therefore, be similar to the family pattern of clinical infection in the case of measles. The epidemiologic study of immunity by birth order in a family gives such distribution of age incidence as would follow the assumption that the introduction of an infection into a family leaves the exposed members of the family immune if they do not contract a clinical case of disease.

Time of Exposure—It appears from such experience that a susceptible child breathing the air in a home harboring a contagious case seldom escapes infection, either manifest or latent. Here the time element in exposure (early observed by Denny³²) characterizes airborne infection. Both the case and the victim continuously breathe the same atmosphere for extended periods of time. In schools, on the other hand, the time of exposure is markedly reduced by the prompt removal of detected cases. Boarding schools in this respect are intermediate between day schools and homes. In a very thorough

POLIOMYELITIS AMONG CHILDREN BY BIRTH ORDER

FIGURE III.—Age incidence of poliomyelitis by birth order. New York State (exclusive of New York City), 1926–1930. (Data obtained through the courtesy of Dr. E. S. Godfrey.)

study of "Epidemics in Schools" recently issued by the Medical Research Council of Great Britain (Special Report Series No. 227³³) the records over 5 years show an average of 14.2 cases for each contagion* introduced into 26 boarding schools and 3.3 cases for each contagion introduced into 2 day schools. The schools were broadly comparable in size and age-distribution and the probability that these figures reflect differences in exposure-time rather than

differences in numbers or immunity-composition of the subjects is borne out by the familiar studies of Dudley³⁴ on the different attack rates of day and boarding pupils.

Intensity of Infection—Data on the intensity of infection so clearly emphasized by Glover¹⁵ are also provided in the same study. An average of 17.2 cases for each contagion introduced into 17 boarding schools for boys, as against an average of 9.1 cases per introduced contagion in 9 girls' boarding schools (in spite of greater degree of reported immunity among the boys) may indicate the greater congestion in

* The word "contagion" is here used in a restricted sense. It refers to the common childhood contagions: measles, German measles, mumps, chicken pox, whooping cough, scarlet fever and diphtheria.

boys' dormitories than in the girls' houses. In the boys' day school, on the other hand, where conditions for the spread of contagion are more comparable, 2.8 cases as against 3.8 cases in the girls' day school per introduced contagion, probably also indicate greater immunity among the boys.

Could it be that differences in climate and method of ventilating homes in England and New England may help to explain the differences in the secondary attack rates in St. Pancras and in Providence, as observed by Wilson ²⁵:

Moreover, Greenwood's data taken from Stocks show secondary attack rates of 25 to 35 per cent with all children under 10 years of age left in whether immune or not and of 45 to 50 per cent with the immunes (those who had had measles) rejected, whereas we find in Providence secondary attack rates on susceptibles under 10 running 75 to 80 per cent, and on all children under 10 from 60 to 65 per cent. Apparently, then, measles is far less infectious under conditions of family life in St. Pancras than in Providence.

Could the conditions which account for one escape in a family so favor other susceptibles as to depress the secondary attack rate as found by Wilson ²⁵:

If next we look to the single primary families which have one specified susceptible escape,

we find the secondary attack rate on the other susceptible to be 55.6 ± 4.6 , and thus the presence of an escape lowers the secondary attack rate more than the presence of an immune.

Could the seasonal difference in secondary attack rates in Detroit, as reported by Top,³⁵ also be explained on the basis of greater confinement of children in air more confined from January through April, causing a greater intensity of infection during those months over the preceding and following months, as shown in Table III.

What interrupted the "seasonally interrupted" epidemic in Providence, also referred to by Wilson ²⁵:

The course of measles in Providence 1929-1934 was characterized by a low incidence in all years but 1931 and 1932 and a major epidemic in those years. . . . The course in 1931 consisted of a moderate epidemic in the late spring falling to a score of cases in September and a sharp rise to epidemic proportions. For this reason we consider that the behavior of measles in 1931-1932 may properly be characterized as a major epidemic seasonally interrupted rather than as two epidemics, one in the late spring of 1931 followed by another in the fall of 1931 and winter of 1932. Hence we shall speak of 1931 as the first and 1932 as the second part of the great 1931-1932 epidemic which contained about six-sevenths of all the measles in the 6 year period 1929-1934. The ratio of secondary to primary cases changes from year to year by more than can be attributed to chance; it is quite high in 1931 and decidedly low in 1932. The ratio of primaries to families also changes being apparently low in the years in which there is little measles—the difference between the figures for 1931 and for 1930 being not significant.

Multiple Exposures—Such a prevalence of disease as subjects a case to multiple infections in different aggregations complicates the determination of the degree of exposure in any one aggregation. Incidence within an aggregation becomes more truly a measure of susceptibility than of degree of exposure to infection for such diseases as the common cold, where lasting immun-

Totals	1,633	1,380	84.6

ity is not conferred, where several attacks per person per season may occur, where adults as well as children harbor the infection. Thus Wilder³⁶ observed that, in the Germantown Friends School, the epidemiologic pattern of upper respiratory infections differs from the pattern of childhood contagions. The incidence of colds is remarkably uniform from year to year, and constant for classes and groups of individuals. Our own analysis of Wilder's data convinces us that school exposure does not ordinarily determine incidence of colds within day schools: absences from colds on Wednesday, Thursday, and Friday account for no more than their proportionate share of the weekly incidence. Assuming broad infection spread (i.e., more than one infection per cold), prevention of colds would depend upon the prevention of multiple infections, for not until the last remaining infection was prevented would a cold be avoided. Studies of methods for the prevention of colds will require isolated aggregations, unexposed to a variety of outside sources, where spread within the aggregation can be measured.

DIFFERENTIATION OF EPIDEMIOLOGIC PATTERNS

The demonstration of an epidemiologic pattern of spread of contagion through aggregations sharing common atmospheres, even though consistent with a demonstrated mechanism for interchange of nasopharyngeal organisms in breathing the common air supply, does not of itself necessarily demonstrate air-borne disease. High correlation between the common occupancy of semi-enclosed atmospheres with other opportunities for infection might lead to similar phenomena.

Close association within aggregations sharing a common air supply also facilitates spread of infection by Flüge droplets and contact. Separation of these modes of spread can be made

only on the basis of more refined analysis of the original data than is possible with records studied and reported through the medium of the droplet or contact theories. The degree of proximity in time and space required by these hypotheses will not, however, explain many well established examples of the spread of contagion.

Exclusion of other Modes of Spread—Thus in the classic outbreak of psittacosis in the Hygienic Laboratory, reported by McCoy,³⁷ both droplets and contact could be rigidly eliminated. Stimson³⁸ states:

During the course of the experiments, which had been undertaken with what appeared to be ample precautions, an outbreak occurred among the personnel at the National Institute of Health, involving 11 persons, 1 of whom died. This would seem to indicate an almost incredible diffusibility of the infection through the air, since some of the victims had not been nearer to the rooms in which the animals were kept behind moist curtains, and with troughs of disinfectant at the doorways, than to pass to and occupy rooms in distant parts of the large buildings. This has led to the assumption that the virus may be spread by the "powder down" thrown off by parrots, which seems to have a diffusibility comparable to the pollens.

Seldom in epidemiology can the factors of droplets and contact be so completely eliminated. In experimental work on animals, however, these variables can be controlled. Thus Dunkin and Laidlaw,³⁹ in reporting on the spread of dog distemper through ferret and dog aggregations in which these factors were carefully excluded, state:

Control dogs cannot be kept free from disease in the experimental house, though kept in separate cubicles and the fullest antiseptic precautions maintained by the attendants to avoid carrying infection from one animal to the other. The dogs were not confined in Topley cages, and so the barrier against spread of infection in their case was less perfect; but we are convinced that aerial spread can and does occur in closed buildings, and we have now abandoned experimental work with dogs in confined spaces and work in the open air.

We pointed out that in the case of ferrets there was practically conclusive evidence of air spread of the virus of dog-distemper in confined spaces over short distances. Our experience with dogs is in entire harmony with this conclusion, as we found that it was impossible to keep a control dog in one cubicle of the experimental house when infected dogs inhabited the adjacent cubicles. We were compelled to abandon this method of experiment and substituted a system which is in large measure successful. It consists in keeping the experimental dogs in kennels and small runs scattered about the grounds around the laboratory buildings. Each kennel has a small run enclosed by fencing and wire netting, and is separate from its nearest neighbour by a distance of 15 to 20 yards. We thus rely on dilution by the external air to prevent the spread of infection from one cage kennel to its neighbour. The attendants who attend to the animals wear the rubber armour which has previously been described, and between each visit to a cage kennel have this armour washed down with lysol. All excreta and all food and drinking vessels are disinfected with lysol every day. The dogs are fed on boiled biscuit and boiled horse meat and bones.

Direct infection of the lung by intranasal instillation (under anesthesia) is now a recognized laboratory procedure. Infection through the respiratory tract by dust containing tubercle bacilli has been reported frequently and has become a routine procedure for experimentally infecting rabbits at the Henry Phipps Institute.⁴⁰ Inhalation experiments have also shown that animals can be experimentally infected by breathing air in a chamber which has been sprayed with pathogenic microorganisms.⁴¹

More recently we have devised a technic for infecting animals in air conditioned chambers supplied with air infected with "droplet nuclei" outside of the chamber. No objection can be raised to the conclusion that these were truly air-borne, for they had been carried in the air stream over long distances. The bacterial concentration of the air was quantitatively controlled, and a relationship demonstrated between the quantity of infection so

breathed and the mortality of the animals. Elaboration of this equipment will permit exposures of large numbers of animals over long periods of time to small concentrations of infection and so imitate the conditions of ventilation in our habitations. Experimental ventilation will bridge the bacteriologic deductions in the first part of this paper with the epidemiologic observations considered in the second part.

Determination of Pattern by Ecologic Factors—Exclusion of other than one mode of spread is not necessary to distinguish an epidemic pattern. Plague in warm climates disseminated by rodents, insects, contact, and droplets may become suddenly transformed into a pneumonic or air-borne pattern better explained by droplet nuclei under conditions of crowding within enclosed spaces during cold weather. Thus Strong and Teague,⁴² after showing experimentally that the period of infectivity of pneumonic plague coincides with the coughing phase of the disease in which the air becomes infected, show:

... from the study of human lesions and those produced experimentally in animals it would appear that endemic plague pneumonia results from inhalation, the primary point of infection being the bronchi.⁴³

They further state that

there is a greater tendency for the disease to spread in cold climates than in warm ones.

In harmony with the above ideas, we find that the only great epidemic of pneumonic plague of modern times occurred in Manchuria during the winter of 1910 to 1911, when the atmospheric temperature was many degrees below zero Centigrade. The disease spread with amazing rapidity. Furthermore, although during the past fifteen years there have been millions of plague cases in India and 2 to 5 per cent of these have been cases of plague pneumonia, yet this form of the disease has not assumed epidemic proportions. The largest epidemic of pneumonic plague in India (1,400 deaths) occurred in Kashmir in northern India at an elevation of 1,524 meters above the sea level during very cold weather.⁴⁴

Strong, in 1935,⁴⁵ summarizing his experiences, states:

Thus it was shown that while the germ of primary pneumonic plague is essentially the same as the organism of bubonic plague (with the exception of exhibiting a uniformly great virulence throughout the epidemic), the portal of entry of the microorganism is different from that in bubonic plague; and that in an epidemic of primary pneumonic plague, rats and fleas play no part in the transmission of the disease, the infection occurring directly from man to man by the droplet method of infection in a somewhat similar manner as in influenza. Overcrowding of the inhabitants in midwinter in small huts (sometimes thirty to forty people in one room) with very little ventilation was an important factor in the spread of the disease in Manchuria.

In the spread of respiratory diseases, the recent investigations of Wells and Stone (1934) upon air-borne infections are of interest, in which they point out the importance of dried infected droplet nuclei derived from droplets less than one-tenth of a millimeter in diameter.

Velocity of Spread—Perhaps the most characteristic feature of the air-borne pattern is the velocity of epidemic spread of infection,⁴⁶ implicit in the droplet nuclei hypothesis. The spread of influenza through army barracks during the World War could not, we believe, have been so swift as that described by Opie, Blake, Freeman, Small and Rivers⁴⁷ if it travelled by steps limited in space to the proximity demanded by the droplet or contact theory and separated in time by the necessary incubation period.

The most striking feature of the epidemic was the extremely rapid spread of the infection throughout the camp. Starting September 22 in a regimental area situated in the extreme southwestern corner of the camp, the disease had within 4 days appeared throughout the camp proper, and 4 days later appeared in two outlying encampments, situated respectively 1 mile north and 3 miles east of the main camp.

No single organization escaped the infection, and during the 30 days from September 20, 23.3 per cent of the total population of the camp suffered from the disease. The figures given herewith are based on a detailed study

of 11,725 cases occurring between September 20 and October 14, and comprise practically the whole of the epidemic. . . .

Infection with hemolytic streptococci may spread as an epidemic through the pneumonia wards of a hospital. A single patient with streptococcus pneumonia is a source of grave danger to every patient in the same ward. Superimposed infection with hemolytic streptococci increases the mortality of pneumonia so that it may reach from 50 to 100 per cent of all patients with pneumonia. . . .

There seems little reason to doubt that the incidence of pneumonia and the death rate of that which occurs might be greatly diminished by preventing all overcrowding of new recruits in barracks and by providing hospital facilities in considerable excess of the routine demand.

Hospital epidemics of streptococcus pneumonia will be prevented when medical officers have that dread of the disease—comparable to our dread of puerperal fever—which is inevitable when its characters are accurately understood.

Transition from Contact to Air-borne Pattern—In this sense measles may or may not assume an air-borne pattern. The School Epidemics Committee report³³ states:

It is a remarkable fact that quite a high proportion of outbreaks of infectious disease did not spread at all. . . .

It will be noted that on the average about 30 per cent of all outbreaks among the boys, and about 40 per cent among the girls, were thus curtailed (that is, limited to one case, though girls were more susceptible than boys). . . .

When introduced into a school, measles may or may not spread, quite irrespective of the number of susceptibles in the population, but it is more likely than any other disease to assume epidemic proportions, at any rate among the boys. . . .

We have other examples of measles gaining access to a school early in the term, hanging fire for a few weeks, and then causing a large epidemic.

A study of the figures in this report will reveal the fact that over one-half of the cases of measles resulted from less than one-fifth of the introductions of the contagion, and that over 90 per cent of the cases resulted from less than one-half of the introductions.

Some factor besides the virulence of the virus or the resistance of the host must be involved in these wide differences in the velocity of spread of a disease which is considered so highly contagious.

The transition from a contact to an air-borne pattern of spread following the introduction of independent means of dissemination of the virus through air is described by Stallybrass.¹⁵

In mumps the author has noticed that the disease sometimes progresses slowly in a school until an outbreak of an epidemic catarrh causes much sneezing, coughing, and spluttering. The mumps epidemic now progresses rapidly. The sudden outbreak marks the transition from contagion to droplet infection and not the alteration of the virus. It has repeatedly been noticed that return cases of scarlet fever follow an attack of a cold in the infecting case; a cold not only increases the amount of mucus discharged into the outer world, but also produces sneezing and coughing; it may also determine a relapse of otorrhoea.

Although Stallybrass uses the words "contagion" and "droplet infection" in a sense differing from that used in this paper (showing, in fact, the confusion in terms applied to the mode of spread of nasopharyngeal infection), there can be little doubt that he recognizes a distinction between the contact and air-borne patterns.

SUMMARY AND CONCLUSION

"Measurement of Sanitary Ventilation" described a method of determining the rate of *removal* of microorganisms from semi-confined atmospheres, with special reference to air disinfection by means of ultra-violet light. An example of the practical usefulness of this method is offered by an experimental study and design of isolation cubicles in which ultra-violet light screens replace solid partitions or where a curtain of light is dropped, continuous with an irradiated reservoir or "ceiling" above the eye level into which any solid cubicle partitions project.

The present paper considers methods of determining the rate of *addition* of microorganisms to semi-confined atmospheres in defining the hazards from air infection and means for the avoidance of such infection.

Sanitary interpretation of analyses of some two thousand samples of air supplied to various human aggregations reveals the consistency between deductions from a theory of air-borne infection, based upon bacteriologic experiments, and epidemiologic evidence of the spread of contagions through aggregations sharing a common air supply. Air-borne infection of animals exposed to quantitative dosage in experimental ventilation further reflects this consistency.

Some few outstanding examples are selected to illustrate an epidemic pattern, fogged by the droplet theory, but clear when viewed through the hypothesis of nuclei from the evaporated droplets. Such a pattern of air-borne spread by droplet nuclei accurately describes the epidemic spread of respiratory infection among individuals aggregated within atmospheres in some degree confined, and can be related to the familiar pattern of epidemic spread of intestinal infection through the medium of water, food, or milk.

Both intestinal and respiratory infection are undoubtedly spread *endemically* by intimate personal contact. The simultaneity or swiftness of *epidemic* spread of both, however, can be better explained by common source media. Each describes its own epidemic pattern true to the physical and biological factors which govern the respective media, just as the patterns of both differ from the pattern of insect spread of disease.

Discovery of the vehicles of transmission of ingested intestinal infection led to successful sanitary measures of control. Recognition of a vehicle of contagion may likewise suggest the means

of preventing epidemic respiratory infection.

Public Health Administration Program

TODAY public health administration is questioning every form of disease, physical and mental; its thought is not limited to the modest possibilities of the clinic, the classroom, or the health leaflet or poster; it demands complete medical service and plans widespread popular education in hygiene as a matter of course, but these activities have been reduced to minor rank in a larger and more significant program. Public health administration now aims to control all environmental factors which affect health. The stu-

pendous task which it appears to have set for itself is not quite frankly avowed, but this task, as I apprehend it, is to define and to apply through social administration a physiologically sound standard of living. Public health administration proposes, in effect, a benevolent dictatorship in the name of health, thus applying in a drastic and wholly unexpected form, the familiar saying that the public health is a concern of government.—S. S. Goldwater, M.D., at dedication exercises, Memorial Hospital, New York, June 14, 1939.

Paratyphoid Fever in Massachusetts*

ROY F. FEEMSTER, M.D., DR.P.H., F.A.P.H.A., AND
GAYLORD W. ANDERSON, M.D., F.A.P.H.A.†

*Division of Communicable Diseases, Massachusetts Department
of Public Health, Boston, Mass.*

A SUDDEN increase in paratyphoid fever occurred in Massachusetts in 1937. From a level of about 6 cases per year, the number reported rose to 267 (Table I). Even in the face of the previous low incidence, Massachusetts was one of the last states to continue the use of triple vaccine. In April, 1937, it was finally decided to omit both the paratyphoids but before monovalent vaccine went into distribution the sudden increase in paratyphoid B infections had been observed and it was decided for the time that a bivalent typhoid-paratyphoid B vaccine would be distributed.

The cases reported in 1937 fall readily into five groups. There were 4 food-borne outbreaks, and the remainder were sporadic cases widely scattered throughout the state.

OUTBREAK I: PASTRY-BORNE

The first and largest outbreak began

early in April, but was not recognized until late in the month. Beginning April 15, several positive and suggestive Widal's were reported on specimens sent in from communities north of Boston. One or two cases seen by the district health officer did not appear to be typical typhoid fever. On April 22 a postmortem culture from a fatal case of supposed typhoid and a stool specimen from a case which had shown a suggestive Widal both showed the presence of paratyphoid B bacilli. All laboratory specimens submitted from the area were scrutinized immediately to discover whether they might not be from unrecognized cases of paratyphoid fever. Inquiries among physicians in the communities brought to light other cases of diarrhea and fever of unknown origin.

An attempt was made to find some common factor among the cases which

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

† The authors, the present and the former Director of the Division, are merely serving as spokesmen for the Division since all of the central office staff and most of the District Health Officers shared in the investigation. Special credit is due to the staff of the Bacteriological Laboratory under Miss E. A. Beckler who handled so creditably the large volume of specimens made necessary by the outbreaks. The department also acknowledges the splendid cooperation of the local boards of health in handling the problems which arose. Dr. Anderson is now Professor of Preventive Medicine and Public Health, University of Minnesota.

1938 (9 mos.)	0	66

* 4 cases not stated

were discovered. They were living in widely separated communities. There had been no large gatherings at which all had been present. Water supplies and milk supplies were numerous. Many of the early cases were among children. This latter point was kept in mind when searching for other common vehicles which might be widely distributed throughout the area. It was found that some gave a history of having eaten jelly rolls. The source was looked up and it was noted that the baker also made cream puffs and a pastry which consisted of two pieces of chocolate cake held together by a thick marshmallow cream. Upon inquiry it was discovered that many of those ill had eaten these other pastries, especially the marshmallow cake. The baker was advised to stop the manufacture of the latter. He had already stopped making cream puffs on March 1.

In searching for the source of the infection all of the food handlers in the

bakery were examined. It was discovered that the man who worked at the wrapping counter and occasionally helped with the filling of the pastry was excreting paratyphoid organisms in his stool. He gave no history of having been ill. After a few positive examinations the organisms disappeared from his stool. It was, therefore, impossible to determine whether he was the cause of the outbreak or whether he himself had picked up the bacilli from the bakery products. Examination of the raw materials which went into the products was undertaken and an organism belonging to the *Salmonella* group was discovered in the powdered egg. It was culturally and immunologically different from those isolated from the stools of patients.

The baker produced large quantities of these inexpensive pastries. They were sold by four delivery men who had routes covering a large number of the cities and towns in the north-eastern part of the state (Table II).

It will be noted that there was one driver who went into 13 out of the 18 communities in which cases occurred. He was, apparently, the most energetic of the delivery men, since he covered more stores than any other, but even so he seemed to have more than his proportion of the cases. In 9 communities where cases occurred, he was the only driver who delivered the products (Table III). His products alone were responsible for 59 cases in contrast to 19 cases chargeable to the products of the other three drivers. This would indicate that the organism was irregularly distributed in the pastries and that the one driver happened to get the most heavily infected products.

It is difficult to believe that all of the cases were caused by pastries delivered on a single day. The date of onset of the first case investigated was March 28, but others continued to occur until the last of May (Table IV). Most of the cases had onsets before the investigation of the outbreak began on April 22. As might

be expected with a pastry product popular among children, the incidence was highest among the lower age groups (Table V).

There was a high degree of laboratory confirmation of the diagnosis. Of the 132 cases, positive stools were found in 116 (88 per cent) and positive or partial agglutination for paratyphoid B was found in 102 (77 per cent). In 86 cases (65 per cent) both the stool and agglutination test confirmed the diagnosis (Table IX).

In the search for additional cases, many family contacts were examined. Including examinations on food handlers, the total number of individuals was 222. Some of these had suspicious symptoms but 10 were found to be harboring the organism without having exhibited any symptoms. These 10 were classed as subclinical cases and were included among the 132 cases recorded for the outbreak.

Four individuals were operated upon before it was discovered that they had paratyphoid fever.

OUTBREAK II: IN GIRLS' COLLEGE

Before the investigation of the first outbreak was entirely completed, attention was called to a number of cases of diarrhea and fever among students in a college in Boston. Examination of blood and stool specimens demonstrated that the illnesses were due to paratyphoid B bacilli. A search for further cases and for the source of infection was immediately begun.

The college had an enrollment of approximately 1,700 students. The only common factor was that all those ill had eaten at the college cafeteria on either June 2 or June 3 during examination week. In going over the menus of the two days, it was found that chicken salad had been served on June 2 and what was left over was made into chicken salad sandwiches on June 3. Among those ill, chicken salad was remembered as one article eaten in practically every instance.

The cafeteria employed 62 workers of whom 13 were full-time employees. Eight persons took part in preparing the chicken salad. Five of these were ill the next day of what proved to be paratyphoid fever. Two of them assisted in preparing the chicken salad sandwiches. Two others of the 8 showed no symptoms, but paratyphoid B bacilli were present in stool specimens. One of these showed positive stools for over a year afterward. The agglutination test in the latter was suggestive and has remained so. She is the only individual followed whose agglutination titer has failed to decrease. It is probable but it cannot be proved that she assisted in removing the meat from the chickens and in dicing it for the chicken salad. While it cannot be definitely established that she was responsible for the outbreak,

the possibility is very great. It should be noted that the kitchen workers were examined 3 years previously, and she is the only one of the workers employed throughout both periods on whom a record of a stool examination 3 years before cannot be found. Throughout all this period her tasks have consisted largely of washing cooking utensils and preparing raw vegetables for cooking. Attempts to associate any of the kitchen workers with recognized cases in the pastry outbreak or with visits into the area where it occurred were entirely unavailing.

The school had closed before the existence of the outbreak was recognized. An especially urgent problem arose when it was discovered that a number of the students enrolled in home economics courses who had been working in the cafeteria had obtained summer positions as food handlers in cafes, hotels, camps, and other summer resorts. It became necessary to learn the destination of these girls and inform local and state health authorities, as well as prospective employers, that stool specimens should be examined to show that they were not carrying the organism. Some of them, in fact, were found to have positive stools.

It was thought important to inform all of the students and the faculty about the outbreak so that the possibility of being operated upon in the belief that they had appendicitis might be prevented and also in order that they might submit themselves to proper medical supervision if they had developed symptoms after departing from the school. State and local health authorities were also notified so that they might check on any that might be handling food.

Seventy-three individuals were found who had probably been infected by eating at the cafeteria. This certainly does not represent the total number, as other unrecognized cases

undoubtedly must have occurred. However, it is readily understood why a larger proportion of the school was not affected. Since it was examination week, the number served at the cafeteria was smaller than usual. Many took all their meals at home or in other dining rooms connected with the school. Moreover, only those who ate the chicken salad were apparently exposed to infection.

Laboratory confirmation was again quite satisfactory. Out of the total of 73 probable cases, 47 (65 per cent) were confirmed by positive stool cultures, 17 others (23 per cent) by positive or partial agglutination tests, and only 9 were clinical diagnoses (Table IX). Stool specimens were obtained too late to expect to find the organisms in some cases. The agglutination test was not helpful in others because of previous inoculation with triple vaccine. Nine individuals with positive stools gave no history of illness.

The spread of dates of onsets gives some information as to the length of the incubation period. Over 90 per cent became ill in 10 days or less, and over 50 per cent had onsets on the 6th,

7th, and 8th days (Table VI). Some had a mild diarrhea on the first or second day and more severe symptoms, including fever, three or four days later.

OUTBREAK III: IN BOYS' SCHOOL

The third outbreak occurred among students and visitors who ate at one or both of two meals served on June 8 during the closing exercises of a boys' private school in the western part of the state a hundred miles from the two previous outbreaks. Both of the meals were prepared by the regular kitchen staff and served by the boys of the school. A large number of those served were relatives and friends of the boys. The menus were very similar and much of the food for the two meals came from the same large containers. Chicken salad, potato salad, turkey dressing, and ice cream were the articles which came under suspicion.

Examination of the food handlers of the school and of the ice cream company failed to reveal a single individual who gave a history of having been ill previous to the outbreak or who showed a positive stool or agglutination test for paratyphoid B.

There was no way of obtaining a complete list of the individuals who had attended the exercises. It was estimated that more than 1,000 may have been exposed. The students had already left school when the investigation began, dispersing to all parts of the United States. Some of them were already on board ship bound for Europe.

Notices were sent to all registered students calling their attention to the possibility of their having been exposed to the infection and recommending that they place themselves under the care of a physician if they had shown any symptoms. They were also warned that those with subclinical infections might convey the disease to

their contacts. State and local health officers were notified of the home addresses of the students.

The number found who had shown symptoms leading to the suspicion of a paratyphoid infection eventually totaled 130. Of this number, 12 had positive stools, 30 others showed positive or suggestive agglutination tests for paratyphoid B, 63 either negative stools or agglutination tests or both, and no specimens were obtained on 25 individuals (Table IX). While laboratory evidence of paratyphoid B infection was obtained in only 30 per cent of the cases, the fact that most of those ill showed onsets within 48 hours after the meals were served would indicate that they contracted their infection at the school (Table VII). That the illnesses were something more than so-

called "intestinal grippe" is suggested by the duration of symptoms which averaged approximately 4 days (Table VIII).

Either stools or blood samples were examined from 75 other individuals who showed no symptoms. Some of these were the food handlers mentioned above. One individual, a student, was found to have a positive stool and 4 individuals were found to have suggestive agglutination tests. These 4 gave a history of having received typhoid-paratyphoid vaccine inoculations.

OUTBREAK IV: CHRISTENING PARTY

The fourth outbreak was a small one which occurred after a christening party on August 15 held in a town near Springfield. This town was thirty miles from the school in which the third outbreak occurred and a hundred miles from the other two. Twenty-nine individuals were probably exposed either by eating at the party or by consuming food which had been prepared for the occasion. Among those exposed, 13 are known to have shown symptoms, of whom 5 had positive stools, 3 others showed positive or suggestive agglutination tests and 5 showed negative tests (Table IX).

In searching for the source of the infection, it was noted the illnesses were limited almost entirely to visitors in the home of the christened child where the party had been held. The father of the child had been ill 10 days before the outbreak. His symptoms, consisting of vomiting and diarrhea, and lasting 5 days, were of sufficient severity that he had gone to a nearby hospital where he was told that he had colitis, but no stool specimens were cultured there. Paratyphoid bacilli were not found in his stool at the time of the investigation, so it is impossible to show that he was responsible for the outbreak, particularly since he had taken no part in pre-

* Many of these also showed positive agglutination tests.

paring the food except for assisting in making pickles. A 4 year old boy was the only member of the household to become ill after the party. All laboratory tests on specimens from members of the family were negative.

DISCUSSION

It has been impossible to trace any connection between these outbreaks. People infected in the first outbreak may have carried the organism to many other parts of the state, but so far no such individuals have been found. The fact that 20 with positive stools and 11 others with positive agglutina-

tion tests were entirely without symptoms emphasizes the importance of sub-clinical infections in this disease and illustrates why its control may be difficult. One of the fundamentals of such control is the ability to recognize cases. When missed cases occur, difficulties increase.

The persistence of the organism in the stools of convalescents adds an additional problem. It will be noted that almost half of those who showed positive stools were still carrying the organism at the end of 5 weeks, one-eighth at the end of 9 weeks (Table X). Others continued positive until

the 28th, 32nd, and 49th weeks, and 5 permanent carriers have been added to our list.

Indications are that the disease will continue in the state for some time. During 1937, 47 sporadic cases were discovered in various parts of the state, practically all of them occurring subsequent to the outbreaks. In the first 9 months of 1938, 66 cases have been reported. Six small outbreaks, totalling 48 cases, occurred in families or in groups eating a common meal. The other 18 were sporadic cases.

SUMMARY

1. There was a marked increase in the incidence of paratyphoid fever in Massachusetts in 1937.

2. Of 267 reported cases, 220 were associated with four outbreaks and the other 47 were sporadic cases.

3. The vehicle carrying the infection was

discovered in two outbreaks (pastry in one, chicken salad in the other), and suspected (chicken salad) in a third.

4. Individuals handling food were found with positive stools in two outbreaks. It could not be definitely proved that they were the source.

5. There were 396 individuals suspected of having paratyphoid B infections: 219 were found to have positive stools, 72 others showed positive or suggestive agglutination tests but negative stools, and 105 were unconfirmed by laboratory examinations.

6. Four individuals were operated upon for appendicitis before the outbreaks were discovered.

7. Five cases have continued for 12 months to excrete paratyphoid B bacilli and have been placed on the carrier list. This is a rate of about 2 per cent permanent carriers, which corresponds to the rate observed for typhoid fever in Massachusetts.

8. Attention is called to the importance of subclinical infections in the control of the disease.

9. Paratyphoid B fever has apparently become established in Massachusetts; 66 cases have already been reported in 1938.

Relation of the Coroner's Office to the Bureau of Vital Statistics*

S. R. GERBER, M.D.

Coroner, Cuyahoga County, Cleveland, Ohio

THE relation between the coroner's office and the bureau of vital statistics has become, in recent years, a problem of vital concern to both groups. Their functions so overlap that each has become more or less dependent on the other for a necessary portion of its work. Because of this it is not only desirable but mandatory that a harmonious reciprocal relationship shall exist between the two offices. This may result only when a meticulous, businesslike attitude prevails in regard to the duties of each office, particularly as to the overlapping functions; when competent, properly trained individuals are employed in both departments, and when resentment ceases against the expenditure of a small amount of extra effort, when occasion demands.

DUTIES OF THE CORONER

It first must be emphasized that the function of the coroner is a vital one. It is one of the least recognized and considered the least important of public offices; yet, sometimes its function far surpasses that of other public offices in importance. For this reason and because its major function has a bearing on the duties of the bureau of vital statistics, its importance cannot

be overemphasized. The office investigates and establishes the causes of certain types of death and the circumstances as defined by state law. This varies somewhat from state to state but, on the whole, there is general agreement. This process, depending upon the incumbent, can be a short, cut and dried, superficial procedure, or a thorough investigation, employing all the armamentarium of science to reach a truthful conclusion. The highest type of procedure of this nature is exemplified by the Medical Examiner's System of New York City. In Cleveland, we pride ourselves on the fact that we are following essentially the same procedure with a fair measure of success, in so far as the state law permits.

Unless all the tools of science—the laboratories of chemistry, pathology, bacteriology, immunology, and ballistics, together with all the evidence derived from the examination of witnesses—are available to the coroner (or medical examiner) he is hampered in his investigation. Having these, the performance of tests and the securing of necessary evidence enables the coroner to make an exhaustive and accurate analysis and to reach his decision sooner. It cannot be too much emphasized that the accuracy of the coroner's verdict varies directly with the accuracy and completeness of his investigation, and similarly affects the statis-

* Read at a Joint Session of the American Association of State Registration Executives and the Vital Statistics Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

tical survey or record of the bureau of vital statistics.

It may be well to point out that not a small part of the statistical information regarding deaths is transmitted from the coroner's office to the bureau of vital statistics. Assuming our experience in the County of Cuyahoga to be representative of the country as a whole, about 12-15 per cent of the deaths in the county are handled by the office of the coroner.

To emphasize the necessity for complete and accurate investigation, many cases can be mentioned where individuals met death as the result of foul play, the true nature of the case being hidden by a series of circumstances in superficial and incomplete investigations. These have been cleared up and the guilty persons brought to justice only through the employment of the laboratory aids mentioned. Conversely, cases are on record where deaths have occurred under highly suspicious circumstances and where innocent individuals have had their lives or liberty placed in jeopardy until the true state of affairs was revealed by these very laboratory aids. Though primarily for the purpose of the coroner's function and record, the accuracy of the investigation affects equally, though secondarily, the work of the bureau of vital statistics.

A function of the coroner's office that is more obviously related to the function of the bureau of vital statistics is the filling out and turning over of the completed certificate of death as soon as possible. I must stress the importance of having a liberal coöperative individual in charge of the local bureau of vital statistics who can understand that on occasion much time may elapse before chemical, bacteriological, pathological, and immunological procedures can be carried out, and as a result the report with the cause of death must be deferred. This may be

irksome, entail more work, and cause some delay in the functions of the bureau of vital statistics, but for the sake of the truth, these handicaps must be accepted gracefully. I have learned that this very act may often be the source of friction between the offices in various parts of the country. Delays of several months to a year have occurred. This to me seems entirely unnecessary except on possible rare occasions.

We have established a working relationship with the Bureau of Vital Statistics which I consider ideal and practical. Probably there is nothing original in it, and parts may be in force in various coroners' offices throughout the country; yet I hope it is of sufficient value to bear explaining.

The majority of our cases are settled conclusively by the Coroner's investigation and/or the gross pathological examination. As the result, the cause of death can be arrived at in very short order, the death certificate filled out, and the information made available to the Bureau of Vital Statistics, within a few up to 24 hours. Should subsequent, more minute histological or chemical examination reveal such additional evidence as to cause a change in the recorded cause of death, this is made in our records and the information is also conveyed to the Bureau of Vital Statistics. Though this entails some trouble, it rarely occurs and is preferable to waiting over a longer period (7 to 10 days) for the final report.

In those few cases, in which there is suspicion or doubt and the Coroner's report is thereby incomplete, the death certificate is filled out with the exception of the cause of death, which is marked "Deferred." Where burial must take place prior to the completion of the Coroner's verdict, the registrar coöperates by issuing a temporary burial permit with our release of the body so as not to inconvenience the

family and undertaker unnecessarily. These cases are usually completed at the end of 1 or 2 weeks, rarely as long as 3 weeks, and the case is closed, statistically speaking.

The personality of the head of each office is important. Naturally, if either or both individuals are short-tempered, impatient, intolerant, and petulant, questions and complaints may arise, which result in ill-will, lack of coöperation, and clash of temperaments, which in turn may produce more irritation thereby setting up a vicious circle of non-coöperation. Personal contact between the heads of the two departments, particularly when questions or criticisms arise, tend to prevent ill-feeling and promote good will.

With the conclusion of his verdict, there may be a tendency on the part of a coroner to consider his official duties as completed and his responsibility to the bureau of vital statistics as over when he fills out the death certificate and hands it over.

Our office does not rest with that and this is probably the secret of the excellent relationship between the two offices in Cleveland. Not only for our own records, which we strive to keep as complete and accurate as possible for statistical investigation or scientific information, but also for the sake of the data necessary for the local bureau of vital statistics, we secure all possible facts pertaining to the cases. Naturally, where human effort is involved, machine-like precision and accuracy are impossible and errors may and do occur. These errors we check and correct as rapidly as possible. In addition (and very important), we have developed an "esprit de corps," whereby when a request comes from the Bureau of Vital Statistics the information is immediately secured though we may not be directly responsible for that particular bit.

This coöperation and failure to draw

a sharp line of demarcation where our functions end and those of the Bureau of Vital Statistics begin is one of the reasons for excellent relationship between the offices.

We have found that certain errors occur more frequently than others on the certificates of death, and that these are a source of irritation and additional trouble to the Bureau of Vital Statistics. The data most often lacking or inaccurately supplied pertain to "Place of Death," "Classification" and "Place of Residence." Many contradictions in the certificate also occur. These errors can and should be avoided by having a qualified individual perform this service personally, or appointing one of the staff to check the facts.

One important source of irritation is the question of legibility. Most physicians fill out their certificates of death with pen and ink, and very frequently the writing is illegible. The typewriter is more satisfactory, but multiple erasures, crowding of words, or typing over words or letters make such a certificate as bad as one illegibly handwritten.

FUNCTIONS OF THE BUREAU OF VITAL STATISTICS

Since we are concerned solely with cases of death that come under our jurisdiction, I shall limit myself entirely to that portion of its work that concerns itself solely with the collection of mortality statistics.

The Director of the Census considers a 90 per cent accuracy in the vital statistics of mortality in any one locality a satisfactory minimum, yet the percentage of error permitted statistically is extremely large. I would assume the purpose of the present activity and effort is directed toward a greater accuracy and facilitation of activity. In some areas, accuracy is greater than others. It would appear that tendency toward error would be

greater where specialization is less, as in the smaller towns, townships, and villages, where the local clerk acts as registrar of vital statistics and in any other capacity necessary. It follows that his expertness in some must suffer.

That there is a definite need that those employed in the bureau of vital statistics be specially trained and educated in medical matters can be well shown by daily practices. First, simple errors in filling in the necessary data, or contradictions, frequently appear in certificates of death, and it requires knowledge and patience to ferret out these mistakes. Occasionally, causes of death are given, either by design or ignorance, that are vaguely or incorrectly stated, and the registrar or clerk must be on the alert for these errors, especially when there is an attempt to "cover up" a suspicious death.

Perhaps the most important and serious function of the bureau of vital statistics as far as the function of the coroner's office is concerned, is the noting of those certificates signed by private physicians, in cases that should have been investigated by the coroner. In this one function, all the faculties of specialized knowledge and education on the part of the clerk must be uncovered in order to prevent such illegal procedure and assist the coroner in the fulfillment of his duty to society.

Criticism of the coroner's office and of the bureau of vital statistics occasionally occurs, and if offered and met with a fine corrective and coöperative spirit, results in improved relationships, and this eventuates in the desired end of accurate knowledge of statistical data. Such a relationship exists between our office in Cuyahoga County and the Bureau of Vital Statistics of Cleveland, Ohio. Occasionally, errors have occurred, and these chiefly in some of the smaller townships and villages where the personnel in office are not specifically trained.

Occasionally the interpretation of the definition of "Coroner's Cases" comes to the attention of the Bureau of Vital Statistics in connection with the question of who shall sign the certificate of death. This concept varies somewhat from state to state, but the interpretation should be liberal in favor of the coroner. The reason for this lies in the premise that it is better to take no unnecessary chances in questionable cases and allow the matter to be settled by the coroner. Usually this can be settled either by a telephone conversation with a presentation of the facts or a brief police investigation. If the coroner presents a certificate of death in any case, his should be accepted in preference to one presented by a private physician. In making such a statement, I assume that no extra fee is made available to the coroner by such effort, so that no selfish interests motivate him.

SUGGESTED IMPROVEMENTS

A study of this type cannot be considered complete without some suggestions for improvement in the relation between the two offices or in the function of each. One such suggestion, in order to prevent passing "Coroner's Cases" signed by private physicians, is to supply the coroner's office with a duplicate copy of death certificates filed each day. This would entail extra work, but it could be limited to the smaller localities, and particularly to those where there is no medical officer in direct charge of the bureau of vital statistics. The expense and trouble would be repaid by the results. It would also cause extra work on the part of the coroner, but he should not protest, since he would be the one to benefit.

The certificate of death used in coroner's cases, is the same as that used in any other case. When a death becomes a coroner's case certain data are

necessary that distinguish it from others, though no room is available for these specialized data on the regular death certificate. These data are of a type suitable for statistical handling, and much statistical knowledge could be drawn from them. Dr. Halbert L. Dunn, has proposed several supplementary forms for fatal traffic accidents. That is an excellent start. Similar specialized forms should be made available for all the other types of cases that come under the jurisdiction of the coroner, including all homicides, other types of accidents, suicides, and the like. Final analysis of the data secured should prove exceedingly interesting and valuable.

In certain areas, confusion exists between the two offices, chiefly in those localities where there are more than one coroner for a given area. Such a

set-up allows confusion because of the tendency to pass responsibility and blame. This can only be improved by altering the system so that there may be a central office of responsibility.

After securing the proper assistance and equipment, an attempt should be made to function in an ideal manner, for which I can suggest no better model than the Medical Examiner's Office, as it now functions in New York City.

CONCLUSION

I have suggested an outline for the ideal functioning of the offices of the coroner and the bureau of vital statistics, and for ideal coöperation between the two offices. Suggestions are made for the improvement of certain functions, for the betterment of relationships and for greater accuracy of statistical data.

Analysis of the Subsequent Course of Diagnosed Cases of Tuberculosis*

RUTH R. PUFFER, H. C. STEWART, M.D., DR.P.H., F.A.P.H.A.,
AND R. S. GASS, M.D.

*Statistician; Epidemiologist; and Clinician; Tuberculosis Study,
State Department of Public Health, Nashville, Tenn.*

THE use of life table procedure in studying morbidity and mortality of those in familial contact with tuberculosis¹ was discussed before the Epidemiology Section of the American Public Health Association by Frost in 1932. Since that time the method has been applied to material in the field of tuberculosis by many of his students. Dr. Frost was also especially interested in the extension of the life table procedure to the study of the course of the disease, which necessitated the development of a method of handling the information regarding the cases as to death (from all causes) retrogression, or improvement of the patients. His intense interest in this analysis was in large part responsible for the development of the method presented here.

The death and survival rates of cases of tuberculosis were summarized by Brieger² in 1937, and the expectation of survival in pulmonary tuberculosis has been shown for cases at the Brompton Hospital.³ In many of these studies the status of cases (living or dead) at certain time intervals after admission to, or discharge from sanatoria was known. For cases found in

this study, however, the periods of continued observation vary, and from the standpoint of development of a better control program it seems important to study the changes in status of tuberculosis cases currently. In the analysis of such clinical data it is necessary to assemble the observations in a form which takes account of the time during which each case remained under observation. For such accounting some modification of the conventional life table is the most convenient method to use.

The procedure followed in calculating the mortality experience will be discussed first. The death rate which it is desired to obtain is the rate known in life tables as the "probability of death" (q_x) within a year.

This is expressed by the ratio $q_x = \frac{d_x}{l_x}$

where l_x is the number present at the beginning of the year and d_x is the number of those who died within the year. This statement, however, assumes that all those not known to have died within the year can be known to have survived through the year. In the data available, some of the cases were under observation less than a full year while others moved from the county so that the period of observation terminated within a year after

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

first observation. Thus a certain number (w_x) of those who entered the experience (l_x) were withdrawn from the experience during the year. Each of the persons thus withdrawn is counted as having been exposed to (and survived) $\frac{1}{2}$ year's experience so that the number at risk for the whole year is taken as

$$l_x - \frac{1}{2}w_x \text{ and } q_x = \frac{d_x}{l_x - \frac{1}{2}w_x}.$$

The probability of survival can be obtained by subtraction of the probability of death (q_x) from 1, as $p_x = 1 - q_x$. If $100q_x$ is the percentage dying during a year, $100p_x$ is the percentage surviving through the year.

From the percentages surviving each year the percentage of those originally at risk who survived h years can be obtained. Thus, since $100p_x$ survive the first year and $100p_{x+1}$ of these survive through the second year, the proportion of the original number who survive through 2 years (100_2p_x) is equal to $100(p_x \times p_{x+1})$. The risk of dying within the first h years (100_hq_x) is $100(1 - {}_hp_x)$.

To illustrate the method, the mortality of cases of moderately advanced tuberculosis during the 4 years following diagnosis is shown in Table I.

Of the 86 persons entering into this experience (l_x) 20 were withdrawn (living) from the experience during the first year (w_x) and 11 died during the first year (d_x). The number at risk was

$$86 - \frac{20}{2} = 76 \text{ and the death rate per 100 was } 100 \times \frac{11}{76} = 14.5 \text{ per cent.}$$

In column 6 the percentage surviving each year is given and it is seen that 85.5 per cent survived the first year. Since 85.5 per cent survived the first year and 93.9 per cent of those

entering the experience in the second year survived through the year, the proportion of the original number who survived through 2 years was $100(.855 \times .939) = 80.3$ per cent. Similarly, the proportion of the original number who survived through 3 years was $100(.855 \times .939 \times .840) = 67.5$ per cent, and through 4 years 59.1 per cent. From these percentages of those originally at risk surviving through the preceding and current year the percentages dying can be obtained, as $100_hq_x = 100(1 - {}_hp_x)$. The risk of dying in the 4 years was 40.9 per cent.

In addition to mortality rates, the experience in regard to other changes in clinical status can be obtained from these observations. In analyzing the data it is necessary (1) to discuss the number of cases that retrogressed or improved among *survivors*, and (2) to base the changes on the number of people *examined*, as changes other than death are found only by examination. The number of survivors examined in a given year varies with the frequency of examination of the cases in the different clinical groups. Some of the cases were not reexamined until the second year following diagnosis. It is not assumed that the changes are recorded for the period in which they occurred but rather for the period in which they were discovered by a subsequent examination. As death is considered the most important observation during a year it is given precedence over any other possible change.

The percentages of retrogressed and improved cases are based on the survivors of a given year who were examined.

As the numbers of survivors through succeeding years can be obtained from the mortality experience, it remains to relate the changes among the persons examined to all survivors. To do this it is assumed that all survivors retrogress or improve at the same rate as

TABLE I

Mortality of Cases of Moderately Advanced Tuberculosis During 4 Years Following Diagnosis

	Number Present at Beginning of Year	Number Withdrawn (Living) During Year	Number Dying During Year	Average Number at Risk During Year	Percentage Dying During Year	Percentage Surviving Through Year	Percentage Surviving Through Preceding and Current Year	Percentage Dying in Preceding and Current Year
	l_x	w_x	d_x	$l_x - \frac{1}{2}w_x$	$100q_x$	$100p_x$	$100\lambda p_x$	$100\lambda q_x$
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
1st year	86	20	11	76.0	14.5	85.5	85.5	14.5
2nd year	55	11	3	49.5	6.1	93.9	80.3	19.7
3rd year	41	7	6	37.5	16.0	84.0	67.5	32.5
4th year	28	8	3	24.0	12.5	87.5	59.1	40.9

those examined. The effect of this assumption may slightly exaggerate the retrogression rates and minimize the improvement rates since those individuals who were reexamined may have included a higher proportion of those retrogressing than of those improving. However, it is not felt that this factor is of such significance as to invalidate any of the results obtained. Although all cases are included in the mortality experience until death or the end of observation, they are included in this experience only until retrogression or improvement is recorded; thus, those at risk for retrogression and improvement do not include all those at risk for death and an adjustment is made to account for deaths among those already retrogressed or improved. To prevent overcounting of those eliminated from the experience, the assumption is made that the mortality in the whole group is the same regardless of any changes in classification. Such an assumption may result in an overcounting in deaths among those who improved and an undercounting among those who retrogressed.

The procedure followed in obtaining the status of tuberculosis cases classed as moderately advanced on initial examination is shown in detail in Table II. Three types of changes are noted: death, retrogression to far advanced disease, and improvement by arrest of the disease or by change in extent so that the classification was changed

to one indicating a less extensive lesion. As the mortality experience was given in Table I it is necessary now to relate the percentages showing retrogression or improvement among those examined to the survivors. In the first five columns of the table the actual findings of the survivors who were examined are given. For instance, in the first year, of the 32 survivors examined, 5 retrogressed to far advanced disease (15.6 per cent), and 2 improved so that the clinical classification was altered (6.2 per cent). In the second year, of the 25 survivors examined who had not already retrogressed or improved, 4 retrogressed (16.0 per cent) and 4 improved (16.0 per cent). As the time period after diagnosis increased the number of survivors examined became smaller, since many of the cases were eliminated by retrogression or improvement.

In columns 6-11 inclusive of Table I the survivors are discussed on the basis of 100 or in terms of percentages. The percentage surviving through the preceding and current year, column 7 of Table I, is repeated in column 6. Of the survivors only those who had not improved or retrogressed in a previous interval were at risk for change and these percentages are given in column 7. To obtain the number of survivors who retrogressed on the basis of 100 it is necessary to apply the percentage of retrogressions among examined survivors (col. 3) to all sur-

TABLE II

Status of Cases of Moderately Advanced Tuberculosis for 4 Years Following Diagnosis

	Survivors Examined					Survivors—Basis of 100					Status at End of Each Year Cumulative—Basis of 100				
	Retrogressed			Improved											
	Total No.	Number	Per cent	Number	Per cent	Through Preceding and Current Year	At Risk for Retrogression or Improvement	Retrogressed Each Year	Improved Each Year	Deaths Among Retrogressed	Deaths Among Improved	Dead (All Causes)	Retrogressed	Improved	Unchanged
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)	(14)	(15)
1st year	32	5	15.6	2	6.2	85.5	85.5	13.3	5.3	14.5	13.3	5.3	66.9
2nd year	25	4	16.0	4	16.0	80.3	62.8	10.0	10.0	0.8	0.3	19.7	22.5	15.0	42.8
3rd year	11	3	27.3	2	18.2	67.5	36.0	9.8	6.6	3.6	2.4	32.5	28.7	19.2	19.6
4th year	3	0	...	1	33.3	59.1	17.2	...	5.7	3.6	2.4	40.9	25.1	22.5	11.5

vivors at risk (col. 7) making the assumption that all survivors retrogress at the same rate as the examined ones. For the first year the number at risk was equal to the number who survived (85.5 per cent); the number who retrogressed was 13.3 per cent ($85.5 \times .156$); and the number who improved, 5.3 per cent ($85.5 \times .062$). While 80.3 per cent of the original 100 survived 2 years, 18.6 per cent improved or retrogressed during the first year. Theoretically, a certain percentage of those who retrogressed or improved in the first year were counted among the deaths in the second year and since death takes precedence over other changes an adjustment was made of 1.1 as the number of deaths on the basis of 100 expected during the second year among those who retrogressed and improved in the first year. This number was obtained by applying the death rate in the moderately advanced for the second year (col. 5 of Table I) to the numbers who retrogressed and improved (col. 8 and 9 of Table II). For example, for the second year the number of deaths on the basis of 100 among those who had retrogressed was 0.8 ($.061 \times 13.3 = 0.8$). In all, there were $80.3 - (13.3 - 0.8) - (5.3 - 0.3)$ or 62.8 per cent who were at risk for change in the second year. Of those

in the experience 10.0 per cent retrogressed ($62.8 \times .160$) and 10.0 per cent improved ($62.8 \times .160$) during the second year.

In the last four columns of the table the results of this analysis are summarized to show the changes over a 4 year period of 100 persons entering into the experience. The percentages of those at risk who were dead from all causes by the end of each succeeding year following diagnosis are repeated in column 12. In column 13 are given the proportions of the original number who retrogressed by the end of each year. These percentages are obtained by totalling the number who retrogressed (col. 8) and subtracting the theoretical number of deaths among them (col. 10). For example, by the end of the second year 23.3 per cent had retrogressed, but 0.8 per cent was subtracted for deaths leaving 22.5 per cent of this group who retrogressed and survived. By the end of the fourth year 25.1 per cent had retrogressed. The percentages of those entering this experience who improved (col. 14) are found in a similar way, and by the end of the fourth year 22.5 per cent had improved. Cases who had neither retrogressed nor improved were considered "unchanged" (col. 15).

This method has been applied to

the data collected in the Williamson County Tuberculosis Study. As this present paper is primarily concerned with a statistical method of analysis of clinical data, you are referred to a paper⁴ in the November issue of the *American Journal of Hygiene* for a more detailed description of the material. However, the course of the disease in far advanced, moderately advanced, and minimal cases in white and colored population groups is shown in the two graphs. The difference in the course of the disease according to the extent of lesion on diagnosis is apparent. The status of cases of tuberculosis in the white population is shown in Figure I. Of those far advanced on diagnosis 73.1 per cent died within the 4 years, and 12.0 per cent improved during the same period. The percentage of those with moderately advanced tuberculosis dying within the

4 years following diagnosis (40.9 per cent) was much lower. However, with the addition of 25.1 per cent of the moderately advanced cases who retrogressed to far advanced condition it is seen that the course of the disease was unfavorable. Of those with minimal tuberculosis 61.4 per cent improved, 19.5 per cent retrogressed, and 0.9 per cent died during this period.

The course of the disease was more rapid for the colored cases as is shown in Figure II. Of the far advanced colored cases, nearly half (48.4 per cent) were dead within 3 months after diagnosis, 79.6 per cent were dead by the end of the first year, and 87.8 per cent by the end of the second year. The percentage of those with moderately advanced tuberculosis dying within 2 years was 63.1. No improvements were recorded for far advanced or moderately advanced colored cases.

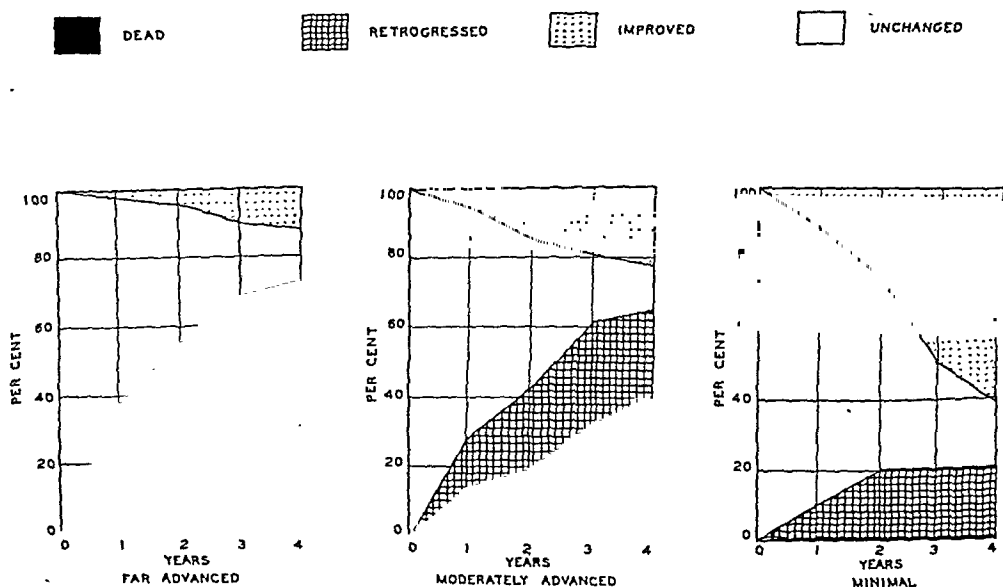

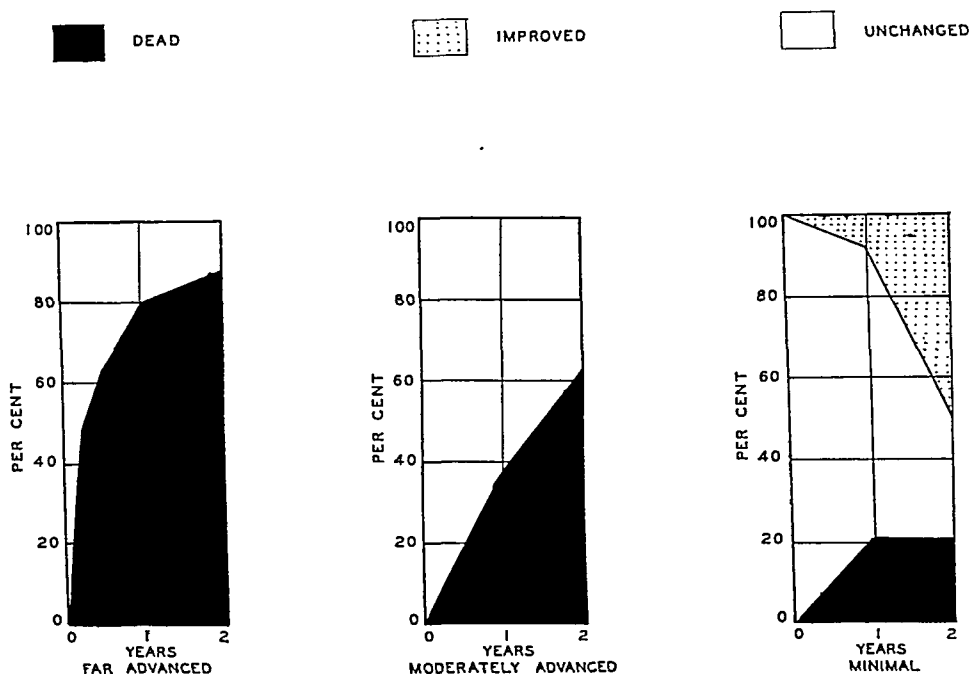

FIGURE II

STATUS OF CASES OF TUBERCULOSIS FOR TWO YEARS FOLLOWING DIAGNOSIS
COLORED

WILLIAMSON COUNTY TUBERCULOSIS STUDY

However, as improvements were noted for those minimal on diagnosis the prognosis for this group appeared to be more favorable.

The analysis of material according to the procedure which has been outlined should be of value to any person charged with the administration of an efficient program for the control of tuberculosis. This method can be extended to studies of other specific aspects of tuberculosis in various age, sex, and color groups and to the studies

of other diseases and conditions affecting health.

DISCUSSION

GAIUS E. HARMON, M.D., F.A.P.H.A.

Epidemiologist, Department of Health, Detroit, Mich.

THE only remarks I wish to make upon Miss Puffer's paper are those of commendation. Some modification of the life table method constitutes our only tool of real value in our search for an answer to many of our epidemiological and medical problems. The modification the authors have developed for the problem with which they had to deal seems adequate and is applicable to other problems.

I suspect that the reason the life table method or some modification of it is not more frequently used may be due to the fact that the keenness of this tool is not realized, or we are too lazy to undertake the thinking and work involved.

One naturally thinks of the desirability of using such a method in trying to determine the effect of different kinds of treatment on cases of tuberculosis. Not everyone is in agreement, for example, as to the efficacy of the modern surgical treatment of tuberculosis, such

as thoracoplasty. The application of such a method as developed by the authors to two large groups of tuberculosis cases, all in the same stage, one group without thoracoplasty, the other with, and a comparison of the results obtained for the two groups should furnish some definite assistance in evaluating this particular kind of surgical treatment. While this has been done, perhaps other studies are desirable to get additional evidence.

In studying many, if not most, problems, it goes without saying that the method would have to be applied to two observation groups; one, of course, to serve as a control.

I would like to ask Miss Puffer as to the number of cases on which the results set forth in the charts are based. The life table method, I judge, would call for a fairly large sample for accurate results.

It has been a pleasure to study and hear this paper presented.

Uses and Abuses of Biochemical Oxygen Demand*

M. STARR NICHOLS, PH.D., F.A.P.H.A.

*Chemist, Wisconsin State Laboratory of Hygiene, and Associate
Professor of Sanitary Chemistry, University of Wisconsin,
Madison, Wis.*

AS a control test in the treatment of sewage by oxidative processes, as a measure of the pollutorial strength of organic industrial wastes, and as a yard-stick in the survey of polluted waters, the biochemical oxygen demand determination has become the most widely used test in modern sanitary control of all liquid wastes. Like most tests which have been devised to measure the progress of natural biologic phenomena it has its uses and it has its limitations. Since the determination is in reality a measurement of biologic oxidation or, more strictly speaking, of the mass metabolic rate of a heterogeneous group of microorganisms, average conditions for normal biological growth must be maintained if optimum results are to be expected.

With domestic sewage these conditions are met satisfactorily since this waste is a mixture of various types of materials which have already partially undergone the degradation process which befalls all biologic material. Moreover, the bacterial flora which accompany this waste find their conditions of existence simply extended to

the final stage in the process—the oxidation and mineralization of these organic matters. This domestic sewage may then be classed as a natural habitat of the organisms which are to perform the oxidation, and for that reason we may expect more concordant results when this waste is under consideration. Experience has shown this to be true. The B.O.D. of these wastes seems to offer the best single test of their pollutorial strength. Industrial wastes, on the other hand, are more apt to be unbalanced in their composition and therefore not so suitable for bacteria propagation and the concomitant oxidation which always accompanies the aerobic attack of bacteria on organic matter.

Beet sugar, beet canning, paper, pulp, and strawboard wastes are good examples of industrial wastes which are high in carbohydrate material. Some of these may be so lacking in compounds of nitrogen and phosphorus that only a small fraction of the real B.O.D. will be obtained if standard procedure is followed. Mineral, chemical, and coke oven wastes are entirely unsuitable for the application of this biologic test. Moreover, those organic wastes high in nitrogenous constituents provide normal conditions for bacterial action, but the

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

5 day period commonly employed may only give a small fraction of the total oxygen requirement which these wastes will demand when they are oxidized naturally under channel conditions in a stream or artificially in an activated sludge plant. The reason for this is found in the fact that the 5 day B.O.D. determination as carried out in the bottle test does not show any usage of oxygen in the oxidation of nitrogen and only up to about 68 per cent of that material usually termed "carbonaceous." Contact with oxidative sludge deposits in stream waters acts similarly to contact beds, trickling filters, and activated sludge, and the oxidations which take place in these stream waters probably carry a velocity constant of a magnitude more comparable with that of a trickling filter than that of a B.O.D. bottle.

The excess oxygen method as now used owes its origin to Frankland who in 1870 made attempts to study the pollution of the Thames River by incubating samples of the water over periods of time up to 7 days. Oxygen values were obtained at the beginning and end of the period selected by boiling off the gases *in vacuo*. Various procedures for measuring the usage of atmospheric oxygen have been employed since that time with improvements accruing up to the present procedure as found in *Standard Methods of Water Analysis*, 8th edition. Dr. E. J. Theriault, who has been largely responsible for the present technic as now used generally in the United States, in 1927 presented a comprehensive review¹ of the development of the B.O.D. test. Much of the early work was carried out under the leadership of Adeney and his associates of the Royal Commission on Sewage Disposal in England.

The mechanism of the test has been studied by many workers and early it was found that the presence of metabolizing microorganisms was a pre-

requisite of satisfactory performance. Thus Butterfield, Purdy, and Theriault² showed that, in a solution of peptone and glucose (5 p.p.m. each) in phosphate dilution water of pH 7.2, no oxygen would be used if this solution were incubated without inoculation with live bacteria; that dead *Acrobacter aerogenes* would likewise cause no usage of oxygen but that inoculation with live *aerogenes* organisms would cause marked usage of oxygen.

Inoculation of dilution water with a stale sewage or river water in those cases where insufficient organisms are present in the waste has become a rather common practice, though from a practical standpoint there probably are only a very few organic wastes which would not supply the inoculum if the bacterial food present were suitable for growth. The influence of inoculation on biochemical oxygen demand was studied by Eldridge³ using sodium bicarbonate dilution water for the determination of the B.O.D. of dilute (0.1 per cent) sugar solutions. He showed that by increasing the inoculum of settled Imhoff tank effluent, progressively, after deducting the B.O.D. due to the added sewage, a progressively higher B.O.D. on the sugar solution was obtained up to the point where about 5 ml. of sewage was present in 250 ml. of sugar dilution.

Holderby and Lea,⁴ working in our laboratory, repeated the work of Eldridge³ but used *sterilized* Imhoff tank effluent in place of Imhoff tank effluent *unsterilized* as used by Eldridge. For inoculum Holderby and Lea used filtered washed cultures of sewage organisms which had been grown on agar. The initial count on the B.O.D. dilution was about 2,000 live organisms per ml. The results of these workers showed increases similar to those of Eldridge in B.O.D. values on the sugar dilution with increasing amounts of *sterile* sewage added and

with the inoculum remaining constant. This seems to show quite definitely that the progressively higher results which Eldridge found were not due to increased seeding but to some other factor or factors present in the sewage which he used for seeding.

Analyses of plain domestic sewage made in our laboratory have shown a total phosphorus content of about 4.0 p.p.m. and a total nitrogen content of about 30 p.p.m. The phosphorus and nitrogen content in the sewage used by Eldridge and described by him as "quite weak due to rainy weather" must have contained at least half these amounts or in the final dilution of 5 ml. of sewage to 250 ml. of sugar dilution as used by him, there would have been available 0.04 p.p.m. of phosphorus and 0.3 p.p.m. of nitrogen. These amounts correspond quite well with the amounts of these elements which Lea and Nichols⁵ found necessary to add to plain sodium bicarbonate dilution water in order to obtain a B.O.D. on a 0.1 per cent solution of glucose of about the same magnitude as that obtained by Eldridge.

There is no doubt that seeding is required by certain types of wastes and also that it was required in the sugar solutions used by Eldridge,³ but the author cannot agree with him that the effect shown was due to seeding but rather was due to the addition of supplementary mineral substances, notably phosphorus and nitrogen, present in the sewage used as the inoculum.

Lea and Nichols⁵ obtained only a B.O.D. of 60 p.p.m. on a 0.1 per cent glucose solution using a dilution water seeded with sewage organisms containing 300 p.p.m. sodium bicarbonate, whereas when this water was supplemented with 0.02 p.p.m. phosphorus and 0.5 p.p.m. nitrogen a result slightly less than 500 was obtained on the same sugar solution. That these mineral supplements must be used

when certain wastes are evaluated by the B.O.D. test is shown by the following experience:

A sewage plant superintendent in Wisconsin was contemplating the acceptance of the effluent from a process used to treat waste sulphite liquor, the "bug-bear" waste of the paper industry. This effluent was found to have a B.O.D. of about 400 p.p.m. by the procedure given in *Standard Methods of Water Analysis*, 8th edition. Before he made his final decision on the acceptance of the waste effluent to his plant he decided to mix this effluent with his domestic sewage and evaluate the mixture by the B.O.D. test. In short, he found that a mixture consisting of 1 part sulphite effluent and 4 parts domestic sewage gave the astounding B.O.D. of 900 p.p.m., whereas calculation of the mixture from the B.O.D.'s of the two separately showed that the mixture should have a B.O.D. of about 240 p.p.m. When the B.O.D. of the sulphite effluent was calculated from the result obtained from the mixture it was found to have a demand of 3,500 p.p.m. which, under the conditions imposed, *i.e.*, mixed with domestic sewage, must be considered the true B.O.D. of this effluent. A B.O.D. was determined by the author on a sample of this waste collected at a different time using *plain* bicarbonate dilution water inoculated with sewage organisms which had been washed free of phosphorus and nitrogen compounds, and the result found to be 550 p.p.m. Samples of this same waste set up at the same time with the remaining inoculated bicarbonate dilution water left in the 5 gallon bottle but supplemented with the mineral salts mixture⁵ gave a B.O.D. of 4,235 p.p.m., a result nearly 8 times as great as with the bicarbonate dilution water of *Standard Methods*, 8th Edition.

The composition of this supplemented bicarbonate dilution water is given as follows:

Ammonium sulphate	2.5 p.p.m.
Tricalcium phosphate (anhy.)	0.01 "
Magnesium sulphate crystals	0.01 "
Dihydrogen potassium phosphate	0.1 "
Sodium bicarbonate	300. "

Stream waters³ examined over widely separated areas contain amounts of phosphorus and nitrogen comparable with that present in this supplemented dilution water. These low nitrogen-phosphorus wastes will use oxygen from the stream in a manner comparable with that shown with the supplemented dilution water since the nitrogen and phosphorus for adequate

in distilled water free from copper.

Results on other wastes showing the increased biochemical demands which are obtained with this dilution water are shown in Table I.

TABLE I

Showing a Comparison of B.O.D. Values Using Plain Bicarbonate Dilution Water and This Water Supplemented by Mineral Salts Containing Both Phosphorus and Nitrogen

Type of Waste Examined	Results in p.p.m.		Per cent Increase in B.O.D. Values Using Supplemented Water
	B.O.D. Values Using Plain Bicarbonate Dilution Water Standard Methods 8th Edition	B.O.D. Values Using Same Water Plus Mineral Supplement	
Glucose. 1,000 p.p.m.	60	470	670
Sulphite Waste Effluent	550	4,325	685
Domestic Sewage	217	221	2
White Water—Paper waste	25	62	148
Bleach Water—Paper waste	30	148	390
Black Liquor—Pulp waste	480	1,450	200
Pea Canning Waste	940	893	—5
Beet Canning Effluent	460	1,570	240
Settled Sewage *	135	140	4

* Results by Dr. W. D. Hatfield of Decatur, Ill.

It is seen from Table I that those wastes (sewages) which contain an adequate natural supplement of phosphorus and nitrogen give comparable B.O.D. values with the two dilution waters. Those wastes low in both nitrogen and phosphorus give much higher B.O.D. values when the supplemented water is used. A satisfactory reason for the low oxygen usage with plain bicarbonate dilution water on these wastes deficient in nitrogen and phosphorus is found in the absence of growth and multiplication of the bacterial flora in the B.O.D. dilution water.⁵

The question naturally arises—why do we want high B.O.D. results on these low nitrogen-phosphorus wastes?

bacterial growth will be furnished by the stream water. The supplemented dilution water is simply giving a true picture of what may be expected when these low phosphorus-nitrogen carbonaceous wastes enter stream waters. The evaluation obtained with plain bicarbonate dilution water of the 8th edition of *Standard Methods of Water Analysis* on these wastes will fall far short of the actual demand. Yet this supplemented water gives comparable results with the plain bicarbonate water on domestic sewage. Criticisms have been made that the supplemented water, containing ammonium sulphate, would cause a usage of oxygen due to this salt. Experiments on this aspect of the problem as published⁵ have shown

practically no production of nitrite or nitrate within the 5 day period and not sufficient in amount up to 30 days to influence the B.O.D. result greatly. Transference of the free ammonia nitrogen to organic nitrogen was noted in all cases, which seems to prove that the nitrogen used is entirely for bacterial cell growth.

Biochemical oxygen demand tests are used with impunity on all types of wastes to get a result. Very often little thought is given to the usefulness of the result obtained. Wastes high in free ammonia and organic nitrogen frequently will not give as high a B.O.D. value as similar wastes lower in nitrogen, yet these high nitrogen wastes will require much more oxygen from an activated sludge treatment process if the sludge is of the nitrifying type. Activated sludges of the nitrifying type are more apt to be present if wastes high in nitrogen are continuously presented for treatment. In these cases, evaluation of the high nitrogen waste should be made partially on the basis of B.O.D. with the added load calculated from the excess of nitrogen shown. Such a condition is found in a municipality in which a packing-house waste is treated with domestic sewage. Ammonium salts such as may be present in a gas plant or coke oven waste may increase the load on these plants far above that shown by a B.O.D. value. Dr. Clair N. Sawyer, working in this laboratory, has shown that ammonium chloride equivalent to 36 p.p.m. nitrogen was capable of extending the maximum rate of oxygen usage of a nitrifying type of activated sludge-sewage mixture from a normal time of about 2 hours up to slightly more than 5 hours with a total usage of oxygen double that of sewage alone before a base rate of the sludge for sludge re-use was obtained.

Substances inhibitory to bacterial growth such as copper in the dilution

water have been known for some time to have a retarding effect upon the B.O.D., but this has not been generally appreciated. Amounts of copper sulphate as low as 0.5 p.p.m. were found by Stovall and Nichols⁶ to be inhibitory to growth of bacteria in swimming pool waters. That small amounts of copper can cause appreciably lower B.O.D. results was emphasized to the author a short time ago. An industrial plant was required by the sewage authority to reduce the pollutorial strength of their waste to the strength of domestic sewage both as measured by B.O.D. Checks on B.O.D. results between the industry concerned and the sewage authority could not be obtained.

Our laboratory entered the picture to help iron out reasons for the continual discrepancy—the industry obtained results invariably 25 per cent lower than the authority. Our laboratory results agreed quite well with the sewage authority. Every detail of the various steps in the procedures from temperature control to reagent standardization was investigated without finding the cause for the discrepancy. The chemist from the industry's laboratory did his work in our laboratory and checked our results and those of the authority. He was also able to use our distilled water in his laboratory and get comparable results. It was then suggested that he test his distilled water with sodium diethyldithiocarbamate for traces of copper. This element was found to be present to the extent of about 0.36 p.p.m. Replacement of a copper valve on the distilled water tank with one made of aluminum solved the difficulty. The B.O.D. values which had been running 25 per cent low were now comparable with those results of other laboratories.

If the use of the B.O.D. test is to be extended beyond the realm of sewage testing for which it was

originally devised, so as to include diverse wastes, attention will need to be given to all conditions of bacterial growth in the B.O.D. test bottle. Not only must toxic and inhibitory substances be excluded from the test bottle, but adequate non-oxygen using minerals of cell metabolism be provided, either by the waste or in the dilution water; otherwise the test falls short of its "biochemical" name. The present plain bicarbonate dilution water as recommended by the 8th edition of *Standard Methods of Water Analysis* of the American Public Health Association is satisfactory for the B.O.D. determination on domestic sewage and its effluents, because these carry their own supplements of nitrogen and phosphorus, but this dilution water is wholly unsatisfactory for this determination on carbonaceous wastes low in soluble phosphorus and nitrogen.

B.O.D. results cannot be expected to give the entire picture of what effect

a given waste will have upon a stream, but they should evaluate each waste on a comparable and equitable basis so that the true strength of these wastes and their expected effect upon a stream or receiving water can be known as fully as possible. The addition of the supplements of phosphorus and nitrogen to the present bicarbonate dilution water of *Standard Methods* does not in itself cause a usage of oxygen but provides conditions as found in stream waters for natural biological growth which is admitted by all workers to be the basis of the B.O.D. test.

Use of the Marginal Punch Card in Tabulating Vital Statistics Data*

EVA W. RAMSEY

*Director, Division of Vital Statistics, State Board of Health,
Salt Lake City, Utah*

IN 1936, with the expansion of the public health program through funds made available by the passing of the Social Security Act, our division was enabled to employ the services of a trained statistician. Our limited legislative budget, however, prohibited the expenditure necessary for rental of mechanical tabulating and sorting equipment used in most state vital statistics offices.

It was at that time that we learned by chance of a system said to accomplish essentially the same results as mechanically operated machinery by the use of an ordinary hand punch and knitting needle, the installation of which entailed practically no expense aside from the cost of the cards.

Somewhat dubiously we visited the office of one of the West's largest department stores and were shown a system of unit stock control operated entirely by the punch card method. Our further study of the problem convinced us of its possibilities as applied to our own needs and we then and there embarked upon the experiment of adapting the marginal punch card, for the first time in a state health depart-

ment, to the tabulation of vital statistics data.

It is interesting to note that, although the first patent was issued in 1896, it was not until 1920 that the marginal punch card was used to practical advantage by Dr. Alan Gregg, who conceived the idea of using individual survey cards in tabulating the results of a hookworm survey in Brazil. He experimented with cards upon which information was coded by cutting notches around the border by hand with scissors. For group separation these cards were placed against the sharp edge of a ruler which fitted into the notches and forced the unnotched cards to a higher level. The separation was then made by picking out the unnotched cards.

A few years later Drs. Hackett and Soper adapted essentially the same system to other disease surveys, this time using a punch which "bit into the margin of the card, transforming the hole into an open notch." Rods or wires were run through a pack of such cards at any of these holes, whereupon the notched cards would fall out, while the others would remain suspended.

In the meantime the system has been developed, improved, and perfected to meet the requirements of every type of statistical analysis. It is seemingly so

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

versatile that it can be applied to any number of diversified procedures with equally successful results.

The card originally used in our Division of Vital Statistics was 4 by 6 inches in size and provided for the coding of practically all the data contained on the mortality certificate.

During a year's experimenting we naturally discovered that certain improvements could be made. The original codes were revised slightly and the size changed to $3\frac{1}{4}$ by $7\frac{3}{8}$ inches, the standard size tabulating card, which we find considerably easier to handle. Our present card contains 90 holes—five to the inch—and provides for over 800 separate classifications. Causes of death are coded on the card according to the *International List*, and all classifications, including the sub-letters, and the sub-numbers under each letter, can be punched in 17 holes.

Cards can be divided and subdivided into all possible groups at the rate of about 5,000 an hour by means of a rod or sorting needle inserted into the holes in succession. The rod will lift out all cards not fulfilling the given condition and there is no necessity of reading the cards or dealing them one by one into piles.

The upper right hand corner is cut off so that it can be seen at a glance whether all cards in the pile are correctly arranged.

Errors in group distribution can be detected at once in piled cards, since each group should present an unbroken line of slots at a given point on the margin. Groups can also be placed together without confusion, since this marginal slot serves to distinguish one from another.

Where the data are broken down into small divisions—for example, infant deaths into hours, days, weeks, months, etc., the process of elimination requires considerable manipulation and the operation cannot be accomplished as

rapidly as would be possible with a mechanical sorter. On the other hand, where only a direct sort is needed, such as the separation of males from females, single from married, or whites from colored, only a single operation of the needle is required and the cards separate themselves into two distinct groups in less time than a machine can be put into operation.

While the necessity of hand counting might be a disadvantage in state offices where great numbers of records are tabulated, it presents no problem in a small state, since after the cards are broken down according to the data needed, the groups are relatively small and can be counted quickly.

In addition to the information actually punched, there is the information conveyed by the ABSENCE of punching. For instance, most deaths in Utah are of whites, so unless the decedent is colored, no punch is necessary. The same applies to male sex, nativity in state, and deaths occurring in homes. A card containing 90 holes may be punched in as few as 9 places and still mean just as much statistically as though the majority of the holes were cut.

The marginal punch card may be drawn up to fit the needs of any type survey, with as little or as much information as may be desirable. At the present time three separate divisions of our State Health Department are now applying the system to their own programs, all on cards of different size and shape.

With the development and growth of our full-time district and county health units the punch card system of tabulating will undoubtedly find its way into the field office. The financial impracticability of elaborate machines for handling such work in the local health units is at once apparent.

There is the possibility, too, of having the operator in the central office

punch two cards simultaneously, the duplicate to be forwarded to the district or county office where it applies.

Under some conditions it may be advisable to use the cards as an index. In this case the card should carry spaces for typing the name, age, file number, and any other data which cannot be indicated by punching. However, when the card is used, not as an index, but as an auxiliary for tabulation only, it need carry only the serial number for identification.

The system is so obviously simple that a person with average intelligence can become a proficient operator in a very short time. As many operators as may be needed can punch or sort at the same time, which is a distinct advantage,

especially at peak load periods when special reports must be rushed through by given dates. Punches and sorting needles are available for use at all times and there are no mechanical devices to get out of commission, thereby delaying the work.

To summarize the advantages of the punch card system:

1. It is practical and inexpensive.
2. It can be used anywhere in the field.
3. It is flexible and can be adapted to any type of survey and to any size card.
4. It is accurate. Possible errors in punching are obvious.
5. It is simple in principle and requires no special training on the part of the operator.
6. It is speedy and any number of operators may work simultaneously. Delays are obviated in that there is no machinery to get out of order.

Districting New Mexico for Sanitation*

PAUL S. FOX, C.E., F.A.P.H.A.

*Public Health Engineer, State Department of Public Health,
Santa Fe, N. M.*

THERE are 31 counties in the State of New Mexico with a total area of 122,503 square miles. The population is approximately 3 per square mile. However, there are many square miles that are uninhabited.

Prior to the adoption of the Social Security Act there were only a few of our counties financially able to maintain full-time health units. The majority of the counties maintained a part-time health officer and in some instances, a public health nurse was employed. With the possibility of securing considerable outside financial aid, study was given to the advisability of placing the entire state under full-time local health service. This was accomplished by the adoption of the District Health Act which divided the state into ten health districts. There are from two to four counties in each health district. The division was made on a population basis and on the ability to pay. The districts have approximately 50,000 people each but the area involved varies from 5,000 square miles to 24,000 square miles. The average is about 12,000 square miles.

The executive is the district health officer, who is employed on a full-time

basis. In addition there are employed in each county at least one nurse and a clerk for the county health department.

Prior to the adoption of this Act the engineering division consisted of one sanitary engineer and a secretary. It was impossible to give close attention to the many sanitary problems which arose in the various communities throughout the state. About all that could be done was to maintain reasonable supervision over public water supplies, sewerage systems, and to a limited extent over milk supplies.

With Social Security funds a trained sanitarian has been placed in each of the ten health districts. Some of our men are graduate engineers who have received supplementary training in sanitation, but the majority of them have received other types of basic education. All but one are college graduates, and he has had 3 years of medicine.

The functions performed by these district sanitarians are basically the same as those performed by the sanitary officer in any full-time health unit. Restaurant and food sanitation, milk supplies, investigations of nuisances, and school sanitation consume most of their time.

In the larger cities we have been successful in getting the community to employ city sanitarians in order to relieve the district men of the burden of milk inspections, etc. In order to supplement the services of district and

* Part of a Symposium on the Expanding Field of Public Health Engineering. Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

city sanitarians the State Health Department has recently employed a Milk Sanitarian whose services are available to the district units and to the cities.

Observations regarding the wisdom of such a districting plan have been very encouraging. Trained personnel is available for the routine work and the investigation of complaints. Much progress has been made in the improvement of market milk supplies and general sanitation. The district sani-

tarians are invaluable in the promotion and operation of the WPA Privy Project.

One district health officer recently made the statement: "If we had as many sanitarians as we have nurses, we could really do something about our high infant mortality rate."

So far we have been so encouraged with the district plan that it is our purpose to add additional county sanitarians as soon as funds are available.

Effects on Health of Gases Produced by the Electric Arc*

LEROY W. LA TOWSKY, M.D.

Philadelphia General Hospital, Philadelphia, Pa.

IN view of the quantity of work done recently on the electric arc and the possible toxic effects of inhalation of the products of arc combustion, a review of the work would seem timely.

Because of his interest in ventilation and air conditioning problems, Dr. E. L. Mac Quiddy of Omaha prompted the Nebraska State Labor Commission to make a survey of the motion picture projection booths in the state. The Commission did this and besides ran some experiments with the arc itself. The results of their study were published in 1936.¹ They found that oxides of nitrogen were given off by the electric projection arc and they stated that there was a possibility of the oxides of nitrogen reaching disagreeable, if not toxic, concentrations in poorly ventilated motion picture projection booths. They stated further that an investigation of the booths in the state showed that most booths could be classified as poorly ventilated.

Fellowships were set up at the Harvard School of Public Health and at the University of Nebraska College of Medicine for the purpose of determining the combustion products of the arc, the effects of inhalation of the

arc fumes, and the proper methods of ventilation of rooms where arcs are used. Some of the results of these investigations were published in the April, 1938, issue of the *Journal of Industrial Hygiene*. More are to follow.²

EXPERIMENTAL

The main apparatus, used in the study of the arc fumes and their effects, consisted of an arc lamp of latest design and in common use in motion picture projection booths. The lamp was operated on direct current of from 40 to 55 amperes and 28 to 36 volts. The electrodes were high intensity 7 mm. positive, and 6 mm. negative copper coated carbons. Fumes from the arc were exhausted by means of a 5 inch flue attached to connections provided on the lamp house. A fan was arranged to draw a current of air through this flue system and discharge it out of doors. The fumes, after leaving the arc housing were conducted through a cooler to bring the temperature to 25° to 28° C. before passing to the animal's exposure chamber, which chamber was inserted in the exhaust flue line. In later experiments this apparatus was modified by inserting a filter in the flue line to take out the particulate matter in the arc fumes. Another piece of apparatus was a

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

specially constructed chamber in which animals were exposed to the particulate matter, devoid of the gases, arising from arc combustion.

Air flow through the arc apparatus varied from 3.8 to 9.4 cu. ft./min. In analysis of the fumes both gaseous and particulate matter were encountered. Oxides of nitrogen and carbon dioxide were collected in Orsat tubes containing the proper absorbents and at flows of approximately 10 liters per hour. The phenoldisulphonic acid method,³ as well as the liquid air nitron method,⁴ was used for the analysis of the oxides of nitrogen. Under the conditions described concentrations of NO₂ from 100 to 205 p.p.m., expressed as NO₂ at 25° C. and 760 mm. pressure, were obtained in the exhaust flue.

Under the same conditions, using the method of Fieldner,⁵ concentrations of 2,450 to 2,770 p.p.m. of CO₂ expressed at 25° C. and 760 mm. pressure were obtained. No sulphur dioxide, carbon monoxide, or ozone could be detected by standard methods of analysis.

TABLE I

Chemical Composition of Ash from the "Suprex" Carbon Arc

Substance	Sample 5,222	Sample 5,223
	Per cent	Per cent
Silicon dioxide	1.79	1.21
Rare earth oxides	65.70	71.80
Ferric oxide	2.26	1.46
Calcium oxide	.53	.20
Potassium oxide	2.26	2.38
Sulphur trioxide	2.35	2.98
Phosphorous pentoxide	.17	.15
Fluoride	10.65	11.31
Boric anhydride	.50	.60

All samples contained a small amount of copper. A suspension of 5,222 in distilled water showed a pH of 5.5. All samples contained some unburned carbon and 5,223 a small amount of manganese. The rare earth substances are for the most part combined with fluoride, the compounds being extremely insoluble in water. The calcium is probably combined with the sulphate.

The particulate matter in the arc fumes on chemical analysis revealed the composition of the ash (Table I).⁶

The specific substances comprising the rare earth oxides mentioned in Table I and their relative proportions are as follows:

	Per cent
Cerium oxide	46
Lanthanum oxide	22
Neodymium oxide	22
Praseodymium oxide	8
Samarium oxide	3

Light field examination showed this ash to be composed of particles or agglomerates of particles in which 79 per cent of the particles were 1.5 to 0.75 microns in diameter. The concentration of ash in the exhaust flue varied from 3.5 to 5.3 mg./cu. ft.

Several groups of animals were subjected to various conditions of exposure to the arc products. In all cases animals were subjected to the highest concentrations of arc substances which were possible to attain with the apparatus used. The pathological physiology of the animals was studied by erythrocyte count, leukocyte count, Ehrlich and Schilling differential counts, hemoglobin, NPN, blood sugar, CO₂ combining power of the blood plasma, icterus index, blood spectrum, and body weight. Upon the death of every animal histopathological studies were made upon microscopic sections of the viscera.

During the course of the study the various conditions of exposure to the fumes were:

1. Exposure to gross arc fumes (gaseous and particulate matter). Acute and chronic exposure.
2. Exposure to filtered arc fumes (gaseous matter only, ash filtered out). Acute and chronic exposure.
3. Exposure to the ash alone.
4. Exposure to concentrations of NO₂, generated from copper and nitric acid, simulating the concentration range found in the arc flue.

In the group subjected to acute con-

tinuous exposure to gross arc fumes were 14 animals, including mice, rats, guinea pigs, rabbits, and cats. Twelve of the animals were dead in from 1 to 22 hours. The animals showed the spectrum of methemoglobin in their blood samples, and a lung edema clinically and microscopically. The guinea pigs showed a polymorphonuclear leukocytosis, and in those two surviving, the leukocytosis subsided in a week. There were no residual lung changes in the two animals surviving.

In the group subjected to chronic exposure to the gross arc fumes there were 5 rats and 5 guinea pigs. These animals were exposed for 1 hour per day 6 days a week to the fumes. Of these animals all 5 of the rats died in from 11 to 38 weeks, showing various stages of acute, sub-acute, and chronic inflammatory processes in their lungs. Of the 5 guinea pigs none died in a period of 10 months' exposure. Their blood samples showed no changes, the lungs showed no changes, and the animals gained weight.

Another group of animals was exposed for 4 hours per day, 6 days a week, to the gross arc fumes. Nine rats and 12 guinea pigs were included in this group. Of the 9 rats all were dead in from 1 to 16 weeks, showing various stages of acute, sub-acute, and chronic pneumonitis with fatty degeneration, abscesses, and gangrene. Of the 12 guinea pigs 11 died in from 2 to 8 months. The average weight loss before death was 100 gm. Each animal showed a polymorphonuclear leukocytosis at death. There was a terminal rise in NPN and a drop in CO_2 combining power of the blood plasma. All animals showed the spectrum of oxyhemoglobin in their blood samples. Histologically the animals showed acute paranasal sinusitis, patchy atelectasis, pneumonitis, fatty degeneration, and dust phagocytosis in their lungs. There were fatty changes in the livers.

The same types of exposure were repeated, but the particulate matter was filtered out of the fumes by the combined use of an oiled spun glass filter and a felt filter. To these filtered fumes, consisting of the gaseous elements of combustion, 12 guinea pigs were exposed 4 hours per day for 7 months. In from 1 week to 7 months 6 of the animals died, showing pneumonitis, patchy atelectasis, and a very few dust phagocytes. Their blood samples showed terminally a polymorphonuclear leukocytosis, increased NPN, and decreased CO_2 combining power of the blood plasma. There was a loss of from 43 to 166 gm. in weight for each animal in from 1 to 5 weeks before death.

Ten rats were exposed 4 hours per day to the filtered arc fumes. All 10 were dead in from 1 to 4.5 months' exposure. Sections of the lungs showed pneumonitis, abscesses, a very few dust phagocytes, and an hyperplasia of the lymphoid tissues.

Ten animals, including mice, rats, guinea pigs, and rabbits, were exposed acutely and continuously to the filtered arc fumes. Eight of the animals were dead in from 2 to 22 hours, showing methemoglobinemia and lung edema.

The findings in the animals subjected to the filtered fumes were identical with those findings in the animals exposed to the gross arc fumes except in the latter there were many dust phagocytes.

In order to compare the effects of inhalation of arc fumes to the effects produced by the inhalation of small quantities of pure NO_2 a group of animals was exposed to NO_2 generated from copper and nitric acid in a concentration range simulating that in the arc exhaust flue. Twelve guinea pigs were exposed 4 hours per day to NO_2 in a concentration range of from 100 to 200 p.p.m. All the animals died in from 3 weeks to 7 months, showing pneu-

monitis, atelectasis, and emphysema. The animals showed a terminal polymorphonuclear leukocytosis, an increased NPN, a decreased CO₂ combining power of the blood plasma, and an average weight loss of 71 gm. in from 1 to 4 weeks. Ten albino rats were exposed in the same manner. All died in from 1 week to 4 months, showing lung edema, pneumonitis, and patchy atelectasis.

Several of the commonly accepted laboratory methods of determining the effects of dust on animals were used in this study. Exposures to silica, talc, bituminous coal, iron oxide, carbon, and orris root were concurrently made as controls, while exposures to Suprex arc ash, Suprex core material, and mixtures of therapeutic and industrial carbon arc ash were made to determine the comparative effects of the arc dusts.

The methods of exposure included actual inhalation of Suprex arc ash in a dusting chamber. Concentrations of the dust varied from 12.8 mg. to 24.7 mg. per cu. ft.; 79 per cent of the particles were 0.5 to 1.5 μ in diameter. Definite changes were observed in the lungs, but detailed study has not been completed.

Another group of 50 rabbits was given intratracheal insufflations of the various dusts according to the method suggested by Kettle and Hilton.⁷ The dosage was 0.2 gm. in 2 cc. of sterile saline. X-rays of the chests of these animals were taken at 7 months and 10 months following insufflation. The animals were killed at 12 months after the initial insufflation at which time sections of the viscera were made for micropathologic study. This work has not been completed to the extent of drawing definite conclusions.

Subcutaneous injections of the various dust samples were made on the same rabbits receiving the intratracheal insufflation. The same dosage of 0.2 gm. of dust in 2 cc. of sterile

saline was used. Sections of the subcutaneous lesions produced were made upon the deaths of the various animals.

Intraperitoneal injections of the various dusts were made into rats following the technic of Miller and Sayers.⁸ Animals were killed at 15-30-60-90-200-360 days and sections were made of the viscera and the abdominal lesions produced. In like manner this study is not completed to the point of drawing conclusions.

DISCUSSION

Various modifications of the electric arc are used under such conditions as motion picture projection, photoengraving, treating with ultra-violet and infra-red lamps, flood lighting with search lights, and electro-welding. Titus, *et. al.*⁹ in 1935 called attention to the respiratory hazard occurring in electric welding. In most of the conditions mentioned the arcs are used in a closed space, and frequently a small closed space. Emphasis is placed on the fact that it is in those conditions of use of an arc in a small closed space without adequate ventilation that dangers from inhalation of the fumes of combustion arise.

The electric arc was discovered in 1812 by Sir Humphrey Davey. Shortly thereafter Cavendish discovered that the oxides of nitrogen were formed around the electric arc. The chemical process by which such a formation takes place has been well explained since today the arc process is one of the commercial methods of nitrogen fixation. The reactions which take place as the arc burns are ¹⁰:

The credit for having made the first observation that the concentration of the oxides of nitrogen might reach toxic levels when electric arcs are being

used should go to Dadlez, a Parisian physician, who in 1927 wrote that the concentration of oxides of nitrogen reaches levels which cause headache in operators and patients in rooms where electric arcs are used for infra-red and ultra-violet therapy.¹¹

Considering the results of the various types of animal exposures as a whole, the findings in the gross fumes exposure group, the filtered fumes exposure group, and the pure NO₂ exposure group, strongly suggest that the oxides of nitrogen play the chief rôle in producing the evil effects of inhaling arc fumes.

The figures of Lehman and Hasegawa as to the levels of toxicity of NO₂ seem to be generally accepted. These concentrations are calculated as NO₂ at 0° C. and 760 mm. pressure.¹²

	<i>p.p.m.</i>
Allowable concentration	39
Allowable one half hour	78
Directly dangerous	117 to 156
Rapidly fatal	780

The concentration range of NO₂ in the exhaust flue is well within this danger level as given by Lehman and Hasegawa. Coltman¹³ writes that on the basis of calculation a high intensity lamp in an unventilated room of 1,000 cu. ft. will bring the concentration of NO (nitric oxide) to 125 p.p.m. in 11 minutes. While with a white flame carbon arc using 1,400 watts, over 2 hours would be required to attain this level. These calculations are based on the assumption that no ventilation at all would occur.

Henderson and Haggard,¹⁴ Ireland,¹⁵ Winternitz,¹⁶ and Underhill¹⁷ have contributed considerably to the knowledge of the effects of inhaling irritant gases. The findings of lung edema in acute exposure, and various lung inflammatory conditions in chronic exposure to the arc fumes fit in with the current knowledge of the effects

of exposure to the group of irritant gases of which NO₂ is a member.

The methemoglobin found in the blood samples of the animals acutely exposed to the arc fumes results from the action of NO₂ on the moist mucosa of the lung in which reaction nitric and nitrous acids are formed. The nitrite ion is absorbed into the blood stream and its action on the hemoglobin causes the formation of methemoglobin. The nitrite ion may also cause a drop in blood pressure with resultant cerebral anemia. This latter action could explain the clinical condition of headache in persons exposed for too long a time to too great a concentration of the arc fumes. However, such a concentration could not be reached in properly ventilated projection booths.

The lung edema which occurred in those animals acutely and continuously exposed to the arc fumes results from injury to the capillary walls by the irritant gas with a resultant physiologic outpouring of fluid into the alveolar spaces. Wells¹⁸ says that this fluid is practically the consistency of blood plasma.

The chronically exposed animals showed various findings in regard to pathological physiology consistent with chronic inflammatory disease of the respiratory tract and resultant loss of appetite and starvation. These findings were an increased NPN, a decreased CO₂ combining power of the blood plasma and a loss of weight.

The results of these studies and similar reports indicate the need for considering the conditions under which electric arcs are operated. There is no basis for criticism of those operating conditions in which there is an exhaust flue in which forced ventilation is in use to remove the products of combustion no matter what the conditions of use are. However, there is danger in inhaling fumes coming from an improperly ventilated arc.

Very recently there appeared in the *Monthly Labor Review*¹⁹ a summary of a survey of the safety standards for motion picture machine operators in 186 cities in the United States having a population of 50,000 or over. One hundred and four of the cities had no laws as to the number or size of ventilation inlets of projection rooms. Ninety-five per cent of the cities had some requirement that systems should be vented to the outer air, but only 19 had definite specification as to area or diameter of vents in relation to room size, number of lamps, or number of men working. The results of the survey show that detailed requirements as to equipment to be used and methods of ventilating the projection room proper and the lamp house connected with the machine are not general. The cities of Hartford, Conn., St. Louis, Mo., and Philadelphia, Pa., as well as the States of Indiana and New York are the only ones that have definite requirements in regard to the system of lamp house ventilation.²⁰

In Hartford, Conn. the 1936 law states that the booth air must be changed at the rate of 30 cu. ft./min. The arc lamp housings must be vented to the outside air and must be provided with automatic shutters.

The St. Louis Law adopted in 1937 states that "each lamp house where carbons are used shall have an independent forced ventilation system of sufficient size to carry off independently of the booth ventilation, all fumes, carbon dust, and carbon monoxide gas generated in the lamp houses while in operation."

In Philadelphia a complete system of direct lamp house ventilation is required in all booths. The system must consist of a motor operated fan, which fan is connected in the booth lighting circuit so that it will switch on and off with the booth lights. The flue must be able to draw not less than 200

cu. ft. per minute per lamp. On spot lights or other projection equipment where the lamp house must be free to move, the exhaust duct is required to terminate in a hood above the machine, and the flue leading from the hood must discharge out-of-doors. Both the lamp house exhaust fan and the general booth exhaust fan are required to have separate sheet metal discharge ducts to the outside air.

In Indiana the state law requires that all arc lamp housings must be connected to the booth ventilation system.

In New York it is required that the arc lamp house of the machine be provided with a chimney and damper which shall carry off the products of combustion in the arc housing to the outside atmosphere.

Drinker and Snell²¹ recommend that the flue pipe from each projector lamp be ventilated at a minimum rate of 12 c.f.m. and that the booth be connected to the air conditioning system of the theater, or else ventilated at a sufficient rate to maintain comfortable temperature with relation to the outside air.

The ventilation system should be a forced one and the fan should be so wired that when the arc is struck the fan turns on automatically.

CONCLUSIONS

It may be concluded from these experimental studies that:

1. There are gaseous and particulate products of arc combustion. The oxides of nitrogen are the main toxic gaseous substances present. The ash is approximately 65 to 70 per cent rare earth substances, especially insoluble Cerium oxides and fluorides. The ash is composed of particles or agglomerates of particles for the most part 1.5 μ in diameter or smaller.

2. The concentration of the oxides of nitrogen in the exhaust flue of a

projection arc is within the range of toxicity if the undiluted fumes are inhaled.

3. Inhalation of the gross and filtered arc fumes, occurring in concentration ranges as exist in the arc exhaust flues, causes the death of common laboratory animals exposed acutely and chronically. Acute exposure results in a methemoglobinemia and lung edema, and chronic exposure results in a pneumonitis, showing patchy atelectasis and chronic inflammatory changes in the respiratory tract.

4. The main conclusions that may be drawn from Drinker's work are that each projector lamp should be connected to a flue in which the fumes from arc combustion are exhausted by means of a motor driven fan to the out-of-doors. The fan should turn on automatically as the arc is struck and the exhauster should draw from 12 c.f.m. to 100 c.f.m. In general it may be said that if ventilation in the booth is adequate to give a comfortable working temperature in the projection room, there is no danger of the toxic gases produced by the electric arc reaching disagreeable concentrations.

DISCUSSION

T. A. FILIPI

Department of Health, State of Nebraska, Lincoln, Nebr.

IN the case of poisoning from fumes from the carbon arc, as with many other public health problems, there are

two sorts of things necessary for the solution of the problem involved. One of these is the securing through experi-

mentation and observation of the necessary scientific knowledge; the other—the part that so frequently lags in the case of public health problems—is the application of that knowledge to the solution of the problem.

La Towsky's paper deals especially with the scientific part. That nitrogen is "fixed" by the electric arc and that the resulting compounds are toxic, has long been known. That an important industrial hygiene problem in connection with the use of the electric arc existed was recognized by the Nebraska State Labor Department in 1935, and some experiments to illustrate the necessity of adequate ventilation in motion picture projection rooms was done by the Nebraska (state) Health Department. Personnel of the Labor Department were shown experiments in which guinea pigs were exposed to fumes from the arc, and thereby the personnel was impressed with the importance of ventilation in connection with the use of the arc. At the conclusion of a series of such experiments a letter for the Labor Department records was written as follows:

Mr. V. B. Kinney
Labor Commissioner
State Capitol
Lincoln, Nebraska
Dear Sir:

Following information from you of a number of cases of chronic illness occurring among motion picture operators employing the carbon arc light for illumination purposes, some of these cases having been tentatively diagnosed as carbon monoxide poisoning, and at your suggestion that the laboratory aid in attempting to determine the nature of poisonous fumes emanating from the carbon arc light, some experiments were undertaken which will be discussed in the paragraphs to follow.

An apparatus was arranged to collect the fumes from above the carbon arc and cause them to pass through an enclosed glass chamber at a regular uniform rate. Guinea pigs exposed to such fumes in this chamber showed restlessness and irritation beginning a few minutes after exposure had started and progressing with increased intensity, the

animals staggering around until at the end of 45 minutes to 1 hour the animals so treated were unable to stand any longer. They were then removed from the chamber and a rapid recovery of the animals to apparently normal state followed.

An absorption train designed to absorb nitric oxide but to permit the passage of carbon monoxide was introduced between the carbon arc and the glass chamber. Tests for nitrites showed that this absorption train did not remove all of the nitric oxide gases but indicated that the amount of such gases reaching the chamber were considerably reduced. Guinea pigs exposed to the fumes in this chamber following such absorption showed no signs of irritation or toxicity at the end of 1½ and 3 hours' exposure respectively.

Spectroscopic examination of the bloods taken from these two series of experiments were made immediately following the experiment. The spectroscopic appearance of the blood from the animal exposed to the unaltered fumes showed an abnormal spectrum identical in appearance with the spectrum of some blood to which had been added a small amount of sodium nitrite. Spectrum of the blood from the other series showed identical with normal blood. No spectroscopic evidence of carbon monoxide poisoning could be found in the blood of animal so exposed.

The fact that nitrogen oxides are produced by the arc and that these oxides are toxic is not new knowledge. However, these brief experiments illustrate the importance of adequate ventilation to prevent exposure of workers to the fumes from the arc. The experiments conducted showed definite evidence of considerable toxicity resulting from the nitric oxides but showed no evidence of other poisonous substances in the fumes from the carbon arc light.

Respectfully yours,
L. O. Vose
Director of Laboratories
(State) Department of Health

La Towsky's experiments took up the scientific problem at about this stage and amplified and extended the scientific knowledge in an able manner. Especially interesting is the fact that certain species of animals were found to be much more sensitive to arc fume than were other species—a fact suggesting that there might be considerable differences in individual susceptibility

among humans. The work he has started on the composition and possible harmful properties of the dust from the arc should be completed and should be extended to include the various types of therapeutic carbons being used.

I understand these experiments as well as other of this nature have been conducted with ordinary atmosphere as present in the respective laboratories—probably atmospheres low in humidity and in carbon dioxide. These experiments found no evidence of carbon monoxide formation. The atmosphere of a small motion picture booth might be considerably different, containing higher concentrations both of moisture and carbon dioxide. It would be interesting to know what changes, if any, would occur to these compounds in the arc say in an atmosphere containing 2 per cent carbon dioxide with a high relative humidity.

The other part of the problem, that of securing adequate ventilation where arcs used in occupied rooms, will depend on educational and regulatory measures and the enforcement of the latter by labor departments, health departments or other organizations—largely governmental—that have to do with promulgating and enforcing regulations relative to safety and health in the industries.

Those engaged in such enforcement have found that the providing of suit-

able ventilation facilities is not sufficient. Inspection at intervals to check on repair and proper operation is also necessary. Instances are known where ventilation fans have been operated in reverse so as to cause arc fumes to be blown back on the operator in motion picture booths.

At one time a great many arc lights were used as sources of heat and ultra-violet radiation used for therapeutic purposes. Some of these were used in physicians' offices and others in private homes. It is probable that in most instances of use, ventilation was adequate. However, it could do no harm for those selling carbons for these arcs to accompany the merchandise with suitable cautions or information as to the toxic nature of the fumes.

This organization, The American Public Health Association, has, through its various committees and subdivisions, recommended standard practices covering many subjects of public health importance. It seems to me that the Industrial Hygiene Section could draw up standard recommendations covering this subject as they probably have covering other subjects of importance in securing safety in industry, these recommendations being suitable for adoption and use by the various agencies dealing with industrial hygiene in those places where the carbon arc might be a health hazard.

A Comparative Study of the Mouse and Guinea Pig Inoculation Methods in the Diagnosis of Rabies*

S. EDWARD SULKIN, PH.D., AND
JOSEPH C. WILLETT, D.V.M., F.A.P.H.A.

*Senior Bacteriologist; and Chief of Laboratories, St. Louis
Health Department, St. Louis, Mo.*

PUBLIC health officials in many parts of this country report an increase in the prevalence of rabies in animals. The possible consequences in man are quite generally recognized. From an unpublished survey we have compiled a 5 year tabulation of rabies examinations in 10 municipal public health laboratories (Table I) which shows an increase in the number of such examinations in several of these cities.

There is a distinct need for improved methods in the laboratory diagnosis of rabies as well as the establishment of certain generally acceptable standards.

In view of the recent experiments of Webster and his associates^{1, 2, 3, 4} a renewed study of the laboratory diagnosis of rabies is both desirable and timely. In the routine diagnosis of rabies one frequently observes that when guinea pigs are injected with material for diagnosis irregularities of incubation period are encountered, and frequently the animals survive the in-

jections. The need for a more desirable test animal is obvious.

Despite reports⁵ in which mice have proved unsatisfactory as test animals, the recent studies of Webster indicate that certain inbred strains of mice are highly desirable for diagnostic purposes. A diagnostic test by mouse inoculation was developed by Webster and Dawson⁴ as an aid to the microscopic method. These investigators used a strain of albino mice indistinguishable from other mice except for their greater susceptibility to neurotropic viruses. The technic described by these investigators was only slightly modified in the present study. An approximate 10 per cent suspension of brain tissue from the ventral portion of the hippocampus major was made using salt solution as the diluent and larger clumps were removed by permitting them to settle in the mortar rather than by centrifugation. Throughout the entire study of guinea pigs received 0.1 cc. of the 10 per cent brain suspension intracerebrally while mice received 0.03 cc. When intramuscular injections were made 0.25 cc. of the suspension was introduced.

We might mention, however, that

impression smears were made of Ammon's horn and a portion of the cerebellum, and a thorough search made for Negri bodies. Throughout this entire study the modification of Van Giesen's stain for Negri bodies described by Nagle and Pfau⁶ was used.

The present study was undertaken to determine the comparative susceptibility of guinea pigs and mice to rabies virus with the view of establishing the certainty with which a confirmatory diagnosis of rabies could be made by animal inoculation.

From 1921 to 1934 a procedure was followed in this laboratory whereby all animal brains reported negative or doubtful on the basis of microscopic examination were injected intracerebrally into each of two guinea pigs in order to confirm the diagnosis. Since 1934, however, animal inoculations were made only when requested by the epidemiologist (Table II). This table summarizes the findings on 1,988 animal brains submitted to the laboratory for examination from 1921 to 1938. Of the total number of brains received

* Examinations made in the St. Louis Health Division Laboratories from 1921 to 1938.

† Reported positive on the basis of microscopic examination.

‡ Found positive by both microscopic and guinea pig inoculation methods.

997 specimens were reported positive, 945 negative, and 56 doubtful. Of the 945 specimens reported negative on the basis of microscopic examination, 29, or 3.7 per cent, proved positive on guinea pig inoculation, while 12, or 21.4 per cent, of the 56 doubtful specimens proved positive on animal inoculation. The average number of days from the time of injection until the time of death of the first guinea pig of each set was 19.7. Incubation periods varied from 8 to 59 days.

In order to determine the relative susceptibility of guinea pigs and white mice to rabies virus, animals were injected with brain emulsion from 27 dog brains showing Negri bodies on microscopic examination. The brain emulsion from each dog brain was injected intracerebrally into two young (200 gm.) and one old (350-450 gm.) guinea pig, and into each of 4 young (4-6 weeks of age) white mice. The animals were observed for a period of 9 weeks. None of the animals were examined for Negri bodies if death took place within 3 days after the injection. These deaths were considered to be

due to trauma. In this group of 81 guinea pigs only 1, 1.23 per cent, died from trauma, while of 104 mice mortality due to mechanical injury was 2.87 per cent.

The results of these comparative experiments are summarized in Table III. Only 9.3 per cent of the 104 mice failed to develop rabies, while 22.2 per cent of the 54 young guinea pigs and 44.4 per cent of the 27 old guinea pigs survived. The average number of days from the time of injection until the time of death of mice showing Negri bodies was 13.3, while the number of days for guinea pigs was 18.4. Furthermore, the first mouse of the series died in an average of 11 days, while the first guinea pig died in an average of 14.5 days. Of the 27 specimens reported positive for Negri bodies, 2 proved negative by the mouse method, while 6 proved negative by the guinea pig inoculation method.

One of these brains (Dog brain No. 2,582) produced rabies in mice in an average of 17 days. One guinea pig receiving an intracerebral injection of this same brain died in 36 days but

Negri bodies were not demonstrated, while the remaining 2 guinea pigs survived. This experiment was repeated at a later date at which time the original dog brain had been glycerinated for 75 days.

Two of 4 mice died in 16 and 20 days, respectively, and Negri bodies were demonstrable, while the 3 guinea pigs survived. Suspecting that guinea pigs were not susceptible to this particular strain of street virus, additional animals were inoculated. Guinea pigs receiving 16 day mouse brain virus died in 13 and 21 days, respectively; while guinea pigs receiving 20 day mouse brain virus died in 15 and 23

days respectively. Negri bodies were demonstrated in each case. This experiment suggests that the mouse is more susceptible than the guinea pig to small amounts of virus of low virulence.

Since St. Louis mice were used in these comparative experiments, due to the limited number of Swiss mice available at the time, an effort was made to determine the relative susceptibility of the St. Louis stock mice and the inbred strain of Swiss mice. The animals referred to in the remainder of this report as St. Louis stock mice consist of three different strains of mice obtained from St. Louis dealers. Ten microscopic

S Animal survived. No Negri bodies found in brain examined after 6 weeks.

— Negri bodies found on microscopic examination.

— No Negri bodies found on microscopic examination.

positive dog brains were used in these experiments. The same supernatant fluid from each specimen was injected intracerebrally and intramuscularly into mice of the two groups.

In order to compensate for possible loss in potency of the virus during the injection, mice were taken one from each cage, in rotation, alternating Swiss and St. Louis strains. One mouse from each group was sacrificed on the 6th, 7th and 9th days, respectively. Impression smears of Ammon's horn and the cerebellum were examined for Negri bodies. The results summarized in Table IV show only a slightly greater susceptibility to the rabies virus on the part of the Swiss mice. The St. Louis stock mice died in an average of 12 days, while the Swiss mice died in an average of 11.2 days. Furthermore, the first animal of the St. Louis group died or was found positive in 9.2 days while the first Swiss mouse

died or was found positive in 8.9 days.

Based upon the guinea pig inoculation method, several years' experience disclosed an error of 3.07 per cent for brains reported negative on the basis of microscopic examination. Suspecting that this low incidence of error might have been due to the uncertainty of the infectivity of guinea pigs, an experiment was undertaken in which animal brains reported negative on the basis of microscopic examination were injected routinely into each of 4 white mice. Both intracerebral and intramuscular injections were made. In this small series of 68 microscopic negative brains, only 2, or 2.94 per cent, proved positive by the mouse inoculation method. In one of these cases, in which a veterinarian's diagnosis of Dumb Rabies was made, Negri bodies were demonstrable in one of the 4 mice 17 days after the inoculation was made. In the other case a diagnosis of "sus-

pected rabies" was made by a veterinarian. Negri bodies were demonstrable in 11 days by the mouse inoculation method.

SUMMARY

A simple technic for the early diagnosis of rabies by mouse inoculation is described as a convenient means of verifying the routine microscopic (Negri body) method. The results of these experiments show that (1) the white mouse is the animal of choice in the laboratory diagnosis of rabies, Swiss mice being of no practical advantage; (2) that the demonstration of Negri bodies in the test animal is the only dependable criterion for a positive diagnosis since clinical manifestations are

frequently too variable and indefinite to be of any value; -(3) that it is practical to attempt demonstration of Negri bodies by sacrificing mice on the 8th or 9th day after the inoculation; and, (4) that the mouse inoculation test offers a more accurate, rapid, and cheaper means of diagnosis than the guinea pig method.

San Francisco's Hotels Are Examined for Cross-Connections

J. C. GEIGER, M.D., F.A.P.H.A., AND A. B. CROWLEY

Department of Public Health, San Francisco, Calif.

AND

G. E. ARNOLD, C.E.

Water Department, San Francisco, Calif.

THE contemplated large influx of visitors to San Francisco during the Exposition Year, 1939, indicated that plumbing of all hotels would be subjected to unusually heavy fluctuating loads. As a preëxposition preparation, a careful program of cross-connection survey was outlined and carried out, the San Francisco Water Department and Department of Public Health working as a single unit.

The principal objective was to guarantee that all hostelrys would be free of cross-connections and that all plumbing would be in proper condition to withstand the severe load brought about by abnormally heavy usage. It was felt that San Francisco was not unlike any other large city and that there were serious potential health hazards in the form of unsafe hotel plumbing and that all must be eliminated long before the guests would begin to arrive.

The term "cross-connection" has been used to designate a connection between a potable and an unpotable water supply. More recently, however, the term has been used to include any indirect connection of the potable supply with a polluted system which

would allow a return flow on the occurrence of a decreased pressure or partial vacuum in the potable supply line.

After several brief conferences of officials involved, a definite procedure was outlined embracing method of inspection to enforce necessary regulations toward abatement of undesirable conditions.

The city was geographically divided into 55 sections and one inspector of the Division of Water Purification of the Water Department and a plumbing inspector of the Department of Health were assigned to the task of original inspection. Each inspector covered a separate section of the city, 12 to 50 blocks, dependent upon the hotel concentration in each section. A block by block method was followed throughout. Daily reports of each inspection were filed in both departments. All reports showing hazardous or suspicious conditions were filed with the Chief Plumbing Inspector of the Department of Health who in turn assigned the regular inspector of the district to make further investigation, issue orders for correction, and reinspect at inter-

vals to determine degree of compliance.

The survey was inaugurated on June 1, 1938, and was completed by January 1, 1939. During this period, 651 hotels had been inspected. Correction of all hazardous conditions was obtained prior to January 15, 1939, which was a little more than a month prior to opening of the Golden Gate International Exposition, February 17, 1939. Limited time required confinement of our program to building piping, fixtures, and equipment. Inspection procedure in each establishment included general inspection of all piping, a notation being made of size, location, and purpose of same; location and type of sewers, condition of all sewer piping; fire system, and general inspection of any plumbing, water treatment equipment or special house storage. Particular attention was given to special sewage equipment such as pumps, syphon ejectors, and other handling machinery. The number, type, and location of all plumbing fixtures were recorded. Special attention was given to fixtures and connections of food handling equipment.

Buildings equipped with dual water supplies were given minute inspections, special attention being given to cross over line safety facilities.

As a result of minor repair work and extensions by resident engineers or maintenance men, inspectors found in some instances a maze of piping that made inspection difficult and time consuming. Unfortunately, in such instances because of turn-over of personnel, blue prints of the house piping were rarely available, and if so, the prints were usually the original building construction plans which did not in any way resemble the existing conglomeration of pipes.

Of the 651 hotels inspected, 82, or 12.6 per cent, were found to have one or more serious plumbing hazards. Most of the defects existed in the

larger hotels which in terms of total rooms and persons exposed would, of course, indicate a higher percentage of hazards.

From the individual reports, a compilation of data was made grouping hazards into 7 classifications, which were further classified under 27 separate items. The number of hazards found in each of the 7 groups were: direct sewer and water department water connections, 22; equipment with submerged inlets, 20; fixtures with submerged inlets, 1,359; prime lines ejectors and pumps, 59; other sources of water, 17; plumbing defects, 12; miscellaneous, 12, or a total of 1,501 hazards.

While enforcing corrective measures, no attempt was made to force owners to replace fixtures or equipment other than to correct connections to them. Sound advice and encouragement were given, however, looking to future remodeling or extensions when fixtures and equipment could be replaced. All owners were encouraged to consider gradual replacement of undesirable fixtures and equipment.

In addition and as an adjunct to the cross-connection survey, the method of routine bacteriological check of the general water supply has been revised. In place of sampling 3 days each week from 8 control points, there has been instituted sampling 3 days per week from 8 control points and 1 day per week from 16 control stations, the additional 8 being storage and pressure tank outlets within the city limits. In addition samples are examined once each week from hotels with dual water supplies.

As a result of this survey and correction of hazardous conditions found, it can be stated that the plumbing fixtures in all of our hotels are reasonably safe.

SUMMARY

The San Francisco Health and Water

Departments completed a cross-connection survey of all hotels prior to the opening of the Golden Gate International Exposition.

A definite procedure of covering the entire city was outlined and an inspector from each department assigned to the survey. Any hazards disclosed were brought to the attention of the regular district plumbing inspector, who followed through and obtained correction.

Six hundred fifty-one hotels were inspected in a period of 6 months; 82, or 12.6 per cent, were found to have a grand total of 1,501 hazards. All were corrected more than 1 month prior to opening of the Golden Gate International Exposition. Bacteriological examination of drinking water was increased to 4 times weekly, and the routine was broadened to include a wider range of storage and flow.

CONCLUSIONS

From this survey it is evident that entirely too much uncontrolled plumbing extensions, repairs, and remodeling are done routinely and unwisely in certain type buildings in large cities. As a result many plumbing hazards and potential hazards are established. Accurate blue prints of such work are not maintained, resulting in confusion because of changing personnel. It is evident that a community would reap large dividends through a small expenditure to finance a survey as herein described at least every 5 years. All building owners would benefit considerably by requiring maintenance men to file corrective blue prints on the premises every time changes were made in plumbing facilities regardless of how minor the nature of these changes may seem.

NOMENCLATURE FOR THE COLON GROUP

THE nomenclature of the group of organisms with which we are chiefly concerned in our examinations of water and sewage, those which have for a long time been called in textbooks the colon-typhoid group, is still far from having been settled, and the usage which one finds both in textbooks and in journals is very confusing. Several years ago an attempt was made to formulate a definite nomenclature which would be followed in this *Journal*, but no agreement could be found among those who were believed to be best able to form an opinion.

Some two years ago the Secretary of the American Water Works Association and Editor of the *Journal* of that Association published a clear statement of the facts and announced the terms which would be used in that *Journal*. This nomenclature has worked acceptably.

In October, 1936,¹ a paper on this general subject was presented to our Association at the New Orleans meeting, in which the matter was discussed clearly and logically. This paper was the result of correspondence which had been carried on for several years by the two authors and we believe represents the best usage in vogue today. The authors suggested that these organisms be known as the "coliform group," and asked that sanitarians in the dairy and shellfish fields should be careful to use a terminology which would neither broaden nor restrict the definition of the organisms included under this term. This group included: "(1) aerobic or facultative anaerobic, (2) Gram-negative, (3) non-spore-forming organisms which (4) ferment lactose with (5) gas formation." This is the coli-aerogenes group of *Standard Methods*, 8th edition. The new *Standard Methods for the Examination of Dairy Products* uses the term "coliform" in the sense here outlined, placing in parentheses the correct Latin terminology (*Escherichia-Aerobacter*).

In dealing with the group of organisms generally used as an index for pollution, it is recommended that authors use the expression "coliform group." While *Escherichia-Aerobacter* is the accepted Latin terminology for this group, the term "coli-aerogenes" is officially used in the 8th edition of *Standard Methods for Water Analysis*, and will also be accepted as long as it remains in that volume,

but the former expression is to be preferred and has found its way during the past two years into the literature dealing with water analysis.

We ask our contributors to be careful in the use of these terms and to follow nomenclature adopted by the American Water Works Association and now by ourselves, for the sake of uniformity and clarity.

INSPECTION AND DISINSECTIZATION OF AIRPLANES

WE have several times commented on what the tremendous increase in the use of the airplane means to us from the public health standpoint,¹ notably very recently² we have mentioned the fact that the *Anopheles gambiae* has reached South America, presumably by means of an airplane from West Africa or on board one of the fast French destroyers which worked in connection with the French air lines between Dakar, West Africa, and Natal, South America, at that time.

In the daily papers we have just been reading with tremendous interest the report of the test flight of the Yankee Clipper from Baltimore to the Azores and Europe and back again and have noted that the regular commercial flights of this line of airplanes is scheduled to begin within a few months so that Europe will soon be connected with us by regular scheduled flights. The port of selection for this country is Baltimore, with Charleston, S. C., as the alternate landing place on account of its freedom from fogs. This news adds particular interest to reports³ from our Public Health Service, some of whose activities in this respect have already been mentioned in our columns.

The *Baltimore Health News*⁴ gives us up-to-date news for that city, where the Surgeon in charge of the U. S. Public Health Service Quarantine Station, is a member of the Advisory Committee on Sanitation of the Baltimore City Health Department. He and his predecessors have served in this way since February 14, 1933.

Quarantine officers make routine examinations of aircraft as well as of other ships coming into Baltimore, and passengers from foreign countries are inspected on arrival. With the inauguration of the transatlantic service doubtless similar arrangements will be made for Charleston, S. C.

Miami has a strategical position as an airport of entry for planes from South America and the West Indies. The inspection there of aircraft is made primarily for the detection of living mosquitoes, particularly *Aedes aegypti*.

During 1938, 398 airplanes from Central America, South America, and Mexico were inspected at the Pan American Airport, Dinner Key, Miami, Fla. Of these, 187 harbored many dead and some live insects. Of 651 insects recovered, 166 were alive. There were 45 mosquitoes on the plane, 40 dead and 5 alive. One was so crushed as not to be identifiable. Of the 5 living mosquitoes, none belonged to disease carrying species. Among the dead there was one *Anopheles albimanus*, which is one of the 26 listed by Covell as being the chief malaria-carrying *Anopheles* of the world. The *Anopheles albimanus* is found in Mexico, in Central America, and in South America, so that the indications are that it came from one of those countries, though it did not survive the trip.

House flies, midges, gnats, and other small flies, beetles, wasps, ants, moths, cockroaches, chinch bugs, as well as two spiders were found during the year.

Our Public Health Service has been on the alert since the airplane became a vehicle of international transportation. One-half hour before landing at Miami and at all other ports of call en route, planes from the south are sprayed with an atomizer containing a standardized pyrethrum extract, 2 grams of pyrethrin per 100 cc., plus 4 parts of a highly refined mineral oil. The planes' ventilators are kept closed for approximately 10 minutes after spraying on overnight stops. After disembarkment of the passengers and crew, thorough spraying is done and the plane closed for the night.

In addition to these precautions, trapping mosquitoes around Miami has been carried on for two years, during which 214,285 specimens of mosquitoes were taken. Each was identified and the survey showed that no new species of mosquito were detected and no species not already known in that area were found. We therefore have every right to feel that our health is being adequately safeguarded in this as well as in many other respects.

LIABILITY FOR INJURIES DUE TO IMMUNIZATION

PROTECTION of individuals against disease by artificial immunization with vaccines, antitoxins, and sera is one of the most important of modern public health procedures. Millions of persons have been thus safeguarded against the ravages of smallpox, diphtheria, typhoid fever, tetanus, rabies, and various other dangerous communicable diseases.

Such immunizations are almost invariably harmless. They may cause some slight discomfort and inconvenience, but any temporary disturbance is as nothing compared to a case of the disease itself.

On rare occasions, however, injuries have resulted from immunizations. In most instances these have been due to negligence and carelessness on the part of the manufacturer of the biological product, the physician using it, or the patient himself. When ordinary care is employed, there is no possible danger from immunization, except in the relatively few cases of those who are unduly sensitive.

When such an injury occurs, the person actually responsible for it will be liable for damages to the injured person. As a rule, this action is based on negligence, which must be proved in a court of law by a preponderance of competent evidence.

An interesting case of this nature was tried recently in the Irish Free State.¹ A county medical officer of health arranged that the boys and girls of several schools should be immunized against diphtheria. He obtained toxoid antitoxin floccules from a reputable manufacturer in England and turned them over to a local medical health officer, who injected the children. Some weeks later, 24 or 25 of those who had been inoculated became ill, 4 in particular of one family

developed tuberculous abscesses, of whom one died from generalized tuberculosis.

The father, a teacher at the College, named Michael O. Chionnfhaolaidh (Kineally in English) sued the physician and the manufacturer in the High Court in Dublin for damages.

There was a great deal of testimony by actual witnesses and by medical experts to show that the proper technic was employed by the physician in giving the injections. Since there was, furthermore, no contract of sale between him and the plaintiffs, and no expressed or implied warranty by him of the quality of the product used, the case against the physician was dismissed by the presiding justice of the court, without submission to the jury.

The case against the manufacturer went, however, to the jury. Here the testimony showed that the manufacturer apparently could not have been negligent in preparing the toxoid and that the product could not have been contaminated with tubercle bacilli. There was also testimony by experts tending to fix the blame on the physician who performed the inoculations. The jury gave a verdict in favor of the manufacturer, which would seem to be justified by the evidence as it is reported. The father who had lost one child and had had three others infected was, therefore, unable to recover from anyone for this legal wrong.

In this country, it has been held by the courts that a manufacturer of a biological product is bound to use due care in its preparation and distribution, so as to protect the health of those using it. For failure to observe these duties, the manufacturer will be liable in cases of resulting injury, but he will not be liable for the improper, careless, or negligent administration of the product by physicians and others.² A municipal corporation will not be liable for injuries due to immunizations performed as part of its governmental functions. Since the individual who causes the injury by his negligence will be personally liable, due care must be taken by health officers and their subordinates and employees, and by city physicians and private practitioners in performing these usually beneficial minor operations.

BOOKS AND REPORTS

Background to Modern Science—
Edited by Joseph Needham and Walter Pagel. New York: Macmillan, 1938.
243 pp. Price, \$2.00.

This most interesting series of lectures had its inception in the belief that the lack of an organization for the study of the history of science at Cambridge, England, constituted a serious gap. In 1936 efforts began to remedy the situation. A committee was formed for arranging courses of lectures on the history of science. The committee has no doubt that the lectures given so far have been meeting a real need, and points to the fact that a great concourse of students, many standing or sitting on the floor, have gathered to hear these expositions of the progress in the sciences during the past 40 years.

It need hardly be said that no one reviewer could speak from intimate knowledge on all the topics discussed in this volume. Consequently the book has been submitted to a number of specialists and this notice is the result.

The names of the various lecturers are sufficient in themselves to assure us of the authenticity of the material presented and also of the excellent style in which the presentation is made. For almost every subject the inherent interest is enriched by the close connection which the author has had with the development of the field of which he writes. Two of the articles, those by Lord Rutherford and Dr. G. H. F. Nuttall, have especial interest as being the last public lectures which they gave. Lord Rutherford died before he could correct his proof and this service was well performed by J. A. Ratcliffe.

There is a uniformity of treatment

unusual in a book written by so many authors, which reflects credit on the editors. Duplication has been avoided to a remarkable extent and each author has kept in mind the fact that he was expounding abstruse subjects to an audience many of whom were either lay or not yet far advanced in the sciences discussed. The result is that the reader is not confused by a great mass of detail. The more important facts are given under each subject in language which is unusually simple and holds one's interest. There is not a lecture which cannot be read with pleasure and profit by the average layman and the whole series can be recommended unreservedly to the public, lay and professional alike.

MAYCK P. RAVENEL

Sanitary Law—In Question and Answer—*By Charles Porter, M.D., Barrister-at-law, and James Fenton, M.D. (4th ed.). London: H. K. Lewis & Co. Ltd., 1939.* 352 pp. Price, \$2.75.

Unlike public health legislation in the United States, which emanates from 49 different legislative bodies of the national government and the states, and shows it, all statutory law concerning public health in England is enacted by a single authority, the British Parliament. In England as here, however, there may also be subordinate legislation, such as by-laws and regulations promulgated by administrative departments. As a consequence, public health legislation in England is both profuse and complex, although it has been codified to a certain extent by the consolidation of the Public Health Acts in 1936.

This book, the first edition of which was issued in 1910, is an excellent guide to public health legislation in England. Its utility is enhanced by a good index. Americans interested in comparing British health legislation with our own scattered, diverse, and lavish health laws will find it of value.

JAMES A. TOBEY

A Textbook of Orthopaedic Nursing—By Evelyn C. Pearce, with a foreword by the late Sir Robert Jones, Bart, and introductory chapter by Dame Agnes Hunt. (2nd ed.). London (24 Russell Square, W.C. 1): Faber and Faber, Ltd., 1939. 230 pp. Price, \$2.50.

The author states that "the object of this book is to help nurses in training in the general hospitals of the country to a better understanding of the treatment of orthopaedic cases and consequently to a deeper interest in this branch of surgical nursing." It is really more than this, as it sets forth in clear and concise form the important facts with which all those interested in orthopedics are concerned. The book is exceedingly well written and illustrated. The preventive viewpoint, as well as the corrective, is stressed throughout. It is written in the language and style which we associate with well prepared English texts. The chapter by Dame Agnes Hunt, R.R.C., is well worth careful reading. Especial attention is given to crippling due to tuberculosis, rickets and poliomyelitis.

This little treatise can be recommended not only to nurses in training, but also to medical social workers, physical educators, and physiotherapists.

RICHARD A. BOLT

Annual Report for 1937, International Health Division, Rockefeller Foundation. New York: Rockefeller Foundation, 1938. 243 pp.

Public health and scientific research work of the Rockefeller Foundation, as reviewed in this report, indicate in a stimulating manner some of the major problems yet unsolved as well as gratifying progress in many fields. Highly valuable digests are given of papers on projects carried out under International Health Division auspices published elsewhere, together with references to the original literature.

Rapid advancement of knowledge regarding the virus diseases opens up promising new fields of investigation and control. At least four of these diseases are being studied, namely, influenza, vaccinia, rabies, and yellow fever. A virus of influenza has been isolated by transfer from man to ferret and transmitted from ferrets to mice. It is being employed diagnostically in standardized tests of human sera in mice for the specific protective antibodies. The virus grown in tissue culture has been used in experimental vaccination "with encouraging results."

The epidemiology of jungle fever is being attacked on several fronts, and improved methods of vaccination are being used to protect persons under exceptional exposure. Steps are being taken to prevent the carrying of infected persons during the incubation period to infectable countries by airplane or otherwise, in addition to precautions against the carrying of infected mosquitoes by airplanes. "A year's experience in the production and application of a cultured yellow fever vaccine virus, during which more than 59,000 persons were inoculated, mostly in Brazil, shows that there is now available a practicable safe method of large-scale immunization."

Studies of malaria, tuberculosis, yaws and syphilis are also reviewed, aid given to state and local health services is briefly described, and assistance given in various countries to the advancement of professional education is outlined.

This is an impressive record of service which should give much encouragement as well as useful information to public health workers. IRA V. HISCOCK

A Biological Approach to the Problem of Abnormal Behavior—
By Milton Harrington, M.D. Lancaster, Pa.: Science Press Printing Co., 1938. 459 pp. Price, \$4.00.

In this lengthy work Dr. Harrington has apparently erected the major part of his structure of theories for a new approach to the problem of abnormal behavior, for which he cleared the ground in his previous book, *Wish Hunting in the Unconscious*, published in 1934. In the early work he suggested a mechanistic psychology as opposed to the motivistic psychology of psychoanalysis, and it may be presumed that the intervening years have seen no change in his opinions concerning the defects and shortcomings of the Freudian explanations.

The book has an introduction, three parts, a résumé and an index. In the introduction, a short and clear opposition to the schools of Drs. Freud, Jung and Adolf Meyer, the author gives many reasons for his rejection of the animistic approach and presents his theory of a psychology built upon a physiological foundation.

Part one, offers the explanation of his basic concepts and methods and the problems of free will and animism, but still attacks Freudism very forcefully; for example, in his diatribe on the substantiation of the phenomena of consciousness, Dr. Harrington says: "... there were added to it the concept of the unconscious . . . a concept of which has been carried to its highest, or perhaps one should say its deepest, level of absurdity in the speculations of Dr. Freud." Since, according to his theory, every symptom hitherto explained on psychological grounds would be explainable physio-

logically, the old psychology has little value except to help in establishing a more direct theory, after which it would be completely nonessential.

In Part two, the author gives his physiological explanation for psychical phenomena. By starting with the conditioned reflex and deducing therefrom that conditioning is a matter of opening new paths through the nervous system for the transmission of nerve impulses, he proceeds to place sensations, emotions, memory and thought, craving and satisfaction, on a physiological or rather neurological basis (which seems more a change of name than a change in conception), dismissing the psychoanalytic theory, at least as it concerns forgotten memories, as untenable, without, however, being in complete agreement with the Watsonian Behaviorists. Similarly, mental adjustment is defined as "a matter of getting relief from nervous tension." Pain, pleasure, mirth, and anticipation are discussed as tension mechanisms, a theory upon which Dr. Harrington erects the third part of his book—the theory of mental disorder of psychopathology.

The author continues in his mechanistic approach to abnormal behavior by defining psychopathology as "the mechanism of behavior functioning in a quite unsatisfactory way," or the sense organs failing to "report" correctly in regard to the situation, or the failure of the "effectors" to respond to the demands made upon them; in other words, regarding psychopathology as neuropathology. Here he demonstrates his disagreement with the theories of the Kraepelinian psychiatrists by stating that there are four factors in the production of abnormal behavior—defective heredity, somatic disease, wrong education, and the stimuli afforded by difficult or trying situations, and avers that the two latter causes have been overlooked by the

followers of Kraepelin. He sets out to show that these factors can be caused by faulty transmission of nerve impulses or the paths "cut in his nervous system by previous experiences."

In spite of the author's determination to differentiate between the psycho-analytic or motivistic conception of the subconscious and his neurological or mechanistic explanation, it is difficult to see that there is any basic difference except in nomenclature. Here is an earnest effort to simplify to the average mind the mental processes by reducing them to a more concrete formula in physiological terms. Perhaps the book's virtue lies in the fact that an equation can only be solved by simplification, the removal of all unnecessary indices and brackets and ciphers; but it appears that where the workings of the mind are concerned such an equation must of necessity involve very complex and varied factors in the first place, which can only be brought to a simple equation by long, arduous and carefully studied work, with perhaps generations of experience, if the final answer is to be found. RALPH S. BANAY

Communicable Diseases for Nurses—By A. G. Bower, M.D., and E. B. Pilant, R.N. (4th ed.). Philadelphia: Saunders, 1939. 547 pp. Price \$3.00.

This latest edition of a book which has made a place for itself in the three editions which have gone before is welcome. It is written for nurses, and stresses the essential steps of nursing care and management. The chapters on Tuberculosis, Syphilis, and Gonorrhea have been rewritten by specialists in these branches, and an entirely new chapter on Public Health Control of Communicable Diseases has been added. The arrangement conforms to the curriculum guide outline.

The changes and additions to the book are well done and this fourth

edition maintains the high standard set by the previous ones. It can be recommended without hesitation for the teaching of nurses as well as a practical guide for graduates. The printing and make-up of the book are excellent.

ELEANOR KEELY

Fundamentals of Dentistry in Medicine and Public Health—By John Oppie McCall, D.D.S. New York: Macmillan, 1938. 161 pp. Price, \$2.75.

This book owes its existence to the fact that the author was invited by Dr. Smillie, Professor of Public Health and Preventive Medicine of Cornell University Medical College, to give some instruction regarding the teeth to medical students. For this purpose he prepared a "Primer" of which the present book is the successor.

The author lays his foundation properly on embryology and histology, then goes on to consider the various diseases to which the teeth are subject and the effect which these diseases have or may have on the general health. Some of the subjects, such as occlusion, pyorrhea, the so-called dead teeth, and caries, are constantly spoken of by the laity and have an interest for everyone.

Of late years diet and its relation to the development of teeth and their health has occupied the stage in an increasing degree. Under this general heading the relation between saliva and dental health is discussed to an extent slightly out of proportion to facts which have so far been established. While the subject is of immense interest the findings are hardly conclusive enough to claim a place in a book confined to fundamentals of dentistry.

The Glossary is particularly good. The illustrations are abundant and the printing is excellent. While intended primarily for medical students and public health workers, it can be recommended also to all dentists as a re-

fresher and to the medical profession, which so far has not enough acquaintance with the underlying principles to enable it to view judicially the fads for which both they and the dentists have been responsible. We refer particularly to the tooth pulling orgy for the cure of everything from hives to Bright's disease. The author is to be congratulated on his clear statements and his ability to condense the vast amount of useful information which he presents. A less able writer might easily have used twice the space without gaining anything in interest or instruction.

We wish for this useful little book the wide circulation that it deserves.

C. F. ELZEA

Health and Unemployment: Some Studies of Their Relationships—
By Leonard C. Marsh, in collaboration with A. Grant Fleming and C. F. Blackler. New York: Oxford University Press, 1938. 243 pp. Price, \$3.00.

This is the seventh publication in the McGill University Social Research Series. It is divided into 5 parts: (1) The elements of the problem—health and economic conditions, indices of public health, unemployment and nutrition; (2) adult workers—nutrition, physical handicaps and mental health; (3) juveniles and adolescents; (4) the family, including minimum standard budgets and relief; and (5) provision of medical care.

In discussing needs based on careful studies, the authors comment as follows:

In form, public health protective services are community-wide. They are intended to safeguard all citizens regardless of their economic standing. But even the benefits of safe milk and foods are limited, however, in a positive sense, to those who are able to purchase the variety of foods and the quantity of milk necessary for good health. Even more is this true of housing; and a correlation between low wages or low skill, and poor working conditions is well established. While the blanket of public health measures

may be equally spread, therefore, it cannot ensure equal coverage while these other limitations on health are unmet. Conditions of nutrition, which have come to the fore in the majority of the present studies, are an outstanding indication of this.

Furthermore, it is revealed that tuberculosis, also high in the ranks of the killing and crippling diseases, is more clearly a disease of the poor. It flourishes under those conditions which are commonly associated with poverty, poor nutrition, unhygienic living conditions, insufficient rest, and over-fatigue. A considerable amount of untreated tuberculosis was found among an unemployed adult group.

Among the unemployed groups examined only 55 per cent of the adults and 47 per cent of the youths could be rated as showing a good nutritive state. Of special interest is the statement that neither social agency cases nor those found on the relief rolls in the earlier years of the depression are representative of the "new unemployed." It is observed that the hardships of a reduced standard of living, and the incidence of ill-health, may well be greater among these latter groups than among the "old" unemployed. The authors advise that a survey to determine this will need not only to distinguish persons who have been on relief for short and for long periods, but also to cover unemployed persons not on relief.

Consideration of the problem of medical care includes a discussion of health insurance and this final paragraph.

The experience of health insurance in Great Britain is now well known: strongly opposed by doctors at the time of its passage over 25 years ago, the system in its essentials today has the complete support of the medical profession. The British Medical Association has placed on official record its approval of extensions of coverage and types of medical service in many directions, which will ultimately establish it as a complete system of medical care for the nation. In Canada many

spheres of medical care require attention before this stage is reached. But several important steps have been taken. Government-assisted medical care for the unemployed has been inaugurated and must be regarded as here to stay. The most immediate need is to improve these services and fill the gaps. Every extension involves responsibilities, but these will have to be undertaken if individual medical care for the mass of the population is to be brought up to the standards of adequacy and efficiency now accepted as necessary in public health facilities in the Dominion.

IRA V. HISCOCK

Historical Directory of State Health Departments in the United States of America—By Robert G. Paterson, Ph.D. Columbus, Ohio: Ohio Public Health Association, April, 1939. 68 pp. Price, \$1.00.

This historical directory is designed to trace the changes which have occurred in each state jurisdiction since the establishment of the first permanent state health organization in Massachusetts in 1869 and to serve as a source of information relating to the terms of each state health officer, the reports which have been issued, and other publications by the state department.

The volume has both historical and personal interest for those whose acquaintance extends over a number of years. It would appear from these data that the present state health officer of Wisconsin has been in office longer than any other, and that seniority is thereafter in the following order: South Carolina, Montana, Kentucky, Georgia, California, Minnesota and Connecticut, though in two cases the service of these state health officers has not been continuous.

A specially useful feature is the bibliography of publications descriptive of state health departments. While not entirely complete, this list is probably the only compilation of its kind. This publication represents a public service

of the Ohio Public Health Association which will be of wide use to the public health profession and should be in every library.

REGINALD M. ATWATER

Baby Care—By May E. Law, M.B., Ch.B. Philadelphia: Lippincott, 1938. Series of 13 Booklets. Price, \$2.00.

Baby Care is a unique and attractive series of thirteen booklets covering the important features of the care of infants from the prenatal period, month by month, through the first year of life. The booklets are encased conveniently in a durable cardboard container. Each section is written in simple, direct English and appropriately illustrated throughout. Mothers will appreciate the many helpful suggestions presented in understandable terms.

The author of this series is a woman physician, graduated from the University of Glasgow. She has had practical experience with children at the Royal Hospital for Sick Children in Glasgow, at Queen's Hospital for Children in London, and in the Hospital for Women and Children at Shadwell. Her interest in preventive pediatrics is attested by the fact that she was medical officer to Infant Welfare Centers in London and served as school medical officer for the County of Essex.

The viewpoint of this series is thoroughly modern and measures up to the standard of present-day pediatrics.

RICHARD A. BOLT

A Pocket Medical Dictionary—By Lois Oakes, S.R.N., Assisted by Thomas B. Davies, M.D. (3rd ed.). Philadelphia: Peter Rilly Co., 1938. 397 pp. Price, \$1.00.

This handy small medical dictionary can be conveniently carried in one's pocket, and read at odd times as one travels or waits for a conveyance. A number of people occasionally read an English dictionary, not to solve cross-

word puzzles, but to improve their vocabularies. This dictionary can serve an equally good purpose in giving information on medical words and terms. It was prepared primarily for medical students—particularly British—as some of the data refer to titles and nomenclature commonly used in Britain. The book is not the less valuable on this account, or because its author is a nurse, for, as a member of examination boards, she has had wide experience in defining names and terms. Moreover, she was assisted by a physician, who is a prominent pathologist.

The supplementary information on abbreviations, dosage, diets, poisons, antidotes, and gas warfare precautions are useful, and the data on this last item indicate the recentness of the revision and its applicability to England.

In a small book all the less common diseases (such as Wernicke's) could not be included, and a few slips might be expected in printing, such as in column 2, page 2, line 13.

JAMES WALLACE

Laws re. Sanitization: Regulatory Measures Concerning the Sanitization of Drinking Utensils in Public Places. *New York: Public Health Committee of the Cup and Container Institute, 1938. 39 pp.*

The adoption of a new word, however much it may be needed, always meets opposition. There are excellent reasons why we should never say sterilization when we mean disinfection or, in the present discussion, the cleansing of drinking glasses and eating utensils. The word "disinfection" connotes so many other processes, its application to the aim of good dish washing methods stands against its use here. It seems certain therefore that the word sanitization will be adopted—in fact it has been adopted in this valuable compilation of laws and regu-

lations which concern the cleansing of public eating and drinking utensils.

There is definite need for a model ordinance to aid health officials and legislators in setting up local sanitary regulations. This compilation of "laws" makes the lack of such a guide all too evident. Examination of only a few of its pages will reveal the wide variety and range of regulatory demands which are more or less in effect in our several states. Regulatory measures which are obviously not enforceable are worse than no rules at all—except that they emphasize the need for intelligent guidance.

The following quotation from the preface is an accurate summary of this timely publication: "Glance at these laws. Some ordinances legally permit the use of chlorine as a sanitization agent; others do not. Sanitization by means of hot water is favored here and shunned there, and there is general disagreement as to temperature requirements and holding time. Although paper service is everywhere acceptable and in practice approved, not every ordinance contains a provision for its use. The required chemical content of rinse waters varies widely as does the time of exposure. Towel-drying is allowed in some places while air-drying is ruled elsewhere. Penalties fixed for violation of sanitization ordinances range in different cities from no stated amount to \$100 or 90 days imprisonment or both. And so on. The diversity of procedures has itself become a public health plague, and the efforts to eliminate contaminated utensils are to that extent frustrated."

A. P. HITCHENS

Medical Vocabulary and Phrases: English, German, French, Italian, Spanish—By Joseph S. F. Marie. *Philadelphia: Blakiston, 1939. 358 pp. Price, \$3.00.*

This is a very useful medical vo-

cabulary giving English, German, French, Italian, and Spanish equivalents. From its arrangement it will be more useful in writing and preparing papers than for translation since the rendition is from English into the other languages. However, many words, especially in English, French, Italian, and Spanish are very much alike and often spelled the same, or very nearly the same. Even for German there are many closely alike, especially scientific terms.

An appendix contains short and clear comments on the pronunciation of the vowels and consonants, syllabification, genders, and plurals of the four foreign languages. Finally 8 pages are given to medical phrases which one constantly uses in the hospital and field. It is said in the preface that the book is intended particularly for physicians and surgeons, public health and military medical officers, and nurses.

Reviewing a dictionary is difficult. One can only look for a certain number of test words. In this instance this has been done by several persons and no errors have been detected. The printing and make-up of the book are excellent. It is a most useful book for any editor or writer.

MAZŮCK P. RAVENEL

The Mental Hygiene Movement from the Philanthropic Standpoint—*New York: Department of Philanthropic Information, Central Hanover Bank and Trust Company, 1939. 73 pp. Reprints available from National Committee for Mental Hygiene, 50 West 50th Street, New York, N. Y., at \$.25.*

This is one of a series of surveys being issued by the Department of Philanthropic Information of the Central Hanover Bank and Trust Company.

The argument is founded on "the

fact that mental disease, like physical disease, is due to natural causes, and, therefore, more or less preventable and more or less amenable to treatment."

The mentally incompetent are divided into the psychotics (the insane), of whom as of January 1, 1937, there were 697,083 in the country, and the mental defectives, of whom, at the end of 1936, there were 99,374 in institutions, and 15,200 on parole, though "the vast majority of them are not confined in institutions but live at large in the community." The economic loss from mental disability, including loss of earnings and the cost of caring for these two classes, has been estimated at more than \$1,100,000,000 per year. The outlook is that more than one million boys and girls now in public schools will spend a part of their lives in institutions for mental disease.

An interesting historical summary is given. It was not until the close of the 18th century that Philippe Pinel in France, William Tuke in England, and Benjamin Rush in America recognized that mental disorder is an illness affecting the mind and not due to demoniacal possession or supernatural causes. The curability of mental disease evolved slowly. Dorothy Dix, in 1841, undertook an inquiry into the treatment of the insane in Massachusetts. The Civil War not only stopped her work but led to a retrogression in the study of the question. In 1844 what is now known as the American Psychiatric Association was formed. It was not until 1875 that the American Neurological Association came into being. There was a bitter fight between the neurologists and psychiatrists, with mutual distrust. The turn of the 19th century gave Kraepelin, whose work brought order out of chaos and shifted the emphasis of psychiatric research from the dead-house to the living patient. Next came psychobiology, under the leadership of

Adolf Meyer, who taught that "mental disease was to be regarded as a 'maladjustment of the *whole personality*, rather than as a brain disease in the purely physiological sense.'" The spark which touched off the present movement came in 1908, when Clifford W. Beers wrote his autobiography, *A Mind That Found Itself*.

Perhaps nothing will appeal to the public more than the humane care and intelligent treatment which is now given at many institutions for the mentally diseased, and the hope which they hold out for cure, not only through surroundings and care, but through medical treatment. High among these comes the treatment for syphilis, which is responsible for approximately 10 per cent of all new cases of mental disorder. Even the most baffling of mental disorders, dementia praecox, which accounts for about 50 per cent of some one-half million patients now in our mental hospitals, seems to be yielding in a fair number of cases to the "shock" therapies recently introduced.

Much attention is now being paid to mental hygiene, which means prevention—beginning with child guidance, schoolroom guidance, and mental hygiene in our colleges and universities. Of this new development it may be said "'a great multitude of persons are living happier and more efficient lives because of their knowledge of mental hygiene.'"

There is a good statement of the needs for the continuance and enlargement of this work. Mental hygiene societies have been formed in 26 states which supplement and reënforce the activities of the National Committee. The most urgent need in mental hygiene is for qualified teachers and practitioners of psychiatry. Fortunately, the requirements are extraordinarily high, the standards being set by the American Board of Psychiatry and Neurology.

Conditions in our mental institutions are not satisfactory. Many state hospitals, even those of enormous size, such as that at Brentwood, N. Y., with 8,000 beds, are overcrowded. In many parts of the country the mentally ill can still be found in almshouses and penal institutions, where medical care is inadequate. The cost is more than 200 million dollars a year, yet the combined funds of 48 states for research is less than one million dollars a year.

This booklet has been carefully prepared for the laity, and the reviewer is treating it from this standpoint, being a layman as far as mental disease goes. It is the clearest and most convincing statement of the situation the writer knows of. It can be commended to all laymen and to medical men as well, most of whom are, as it were, frightened away from mental diseases by the many new terms coined by psychiatrists and psychologists, which are not understood even by many of those who specialize in these branches.

The booklet is interestingly written, easily read, and free from the technical language which has led to confusion and obscured the facts by a mass of new-made verbiage. MAZÏCK P. RAVENEL

Your Baby and Child: A Book for Mothers—*By M. C. Overton, M.D., F.A.A.P. Lubbock, Texas: Your Baby & Child Publishing Co., 1936. 224 pp. Price, \$2.00.*

This is a simply written book in words which the mother can easily understand. It is made up of a number of short chapters covering practically all of the questions which an intelligent mother might ask. The arrangement of the material is by no means systematic, but a complete table of contents and index in large type make it easy to find the topic under discussion. The advice given to mothers follows generally modern pediatric practice.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

British Health Services—According to this author, 3,600,000 plus new homes have been provided in slum clearance schemes and every third family lives in a post-war house. Yet, he says, the speed at which some local authorities have tackled slum clearance has varied between dead slow and dead stop. How would he characterize the feeble American efforts in this direction?

ASBURY, W. The Future of Public Health Services. *J. Roy. San. Inst.* 59, 12:727 (June), 1939.

In the Spring of 1839—Many other interests are making publicity capital from baseball's hundredth anniversary, so there seems to be no reason why public health shouldn't have an inning. The story of the centennial of Abner Doubleday's game will entertain us one and all.

CASWELL, J. E. Baseball 100 Years Ago. *J. Health & Phys. Ed.* 10, 5:278 (May), 1939.

Rickettsiae Vaccines from Chick Embryos—Enough vaccine to immunize 135 persons against spotted fever can be cultured on a chick embryo. The vaccine thus prepared has been found effective for guinea pigs.

COX, H. R. Rocky Mountain Spotted Fever. *Pub. Health Rep.* 54, 24:1070 (June 16), 1939.

Getting Medical Advice—In sampling low income groups in New York City, a researcher asked 365 self-supporting families about how and where they got their medical services. Her findings suggest that in this group, at least, the free choice of doctors usually isn't very free and the choice is rarely very wise.

DAVIS, M. M. A Doctor of Their Choice. *Survey Graphic.* 28, 7:431 (July), 1939.

Water Supplies and Caries—In two cities in Illinois there are enough fluorides in the drinking water to cause a mild degree of dental mottling. In two nearby cities the water is almost free of fluorides. Children twelve to fourteen years old in the first two cities have less than half the incidence of dental caries than have similar groups of children in the cities with water free from fluorides. There was no discernable difference in the saliva of the children in the various cities, but the difference in oral lactobacilli reflected the differences in carious teeth. This paper should be on your "must" reading list.

DEAN, H. T., *et al.* Domestic Water and Dental Caries, Including Certain Epidemiological Aspects of Oral *L. acidophilus*. *Pub. Health Rep.* 54, 21:862 (May 26), 1939.

"The Nurse Says"—Public health nursing will be vastly improved in general when these factors (among others) are bettered: clinic services that do not belie the nurse's promises to the patient; complete and adequate histories on all patients before visiting; better distribution of community nursing resources; and actual services when needed—not merely advice. This is another of the interesting verbatim reports on what the nurse said to the patient and vice versa.

DERRYBERRY, M. Administrative Procedures that Interfere with Effective Public Health Nursing. *Health Officer.* 4, 1:18 (May), 1939.

Intracutaneous Smallpox Vaccination—Calf lymph virus gave a slightly higher percentage of takes than did

intracutaneous vaccination with chick virus, but severe reactions were less frequent with the latter. There was little difference in the scar.

ELLIS, R. W., and BOYNTON, R. E. Small-pox Vaccination: A Comparison of Vaccines and Techniques. *Pub. Health Rep.* 54, 23:1012 (June 9), 1939.

The New Public Health—This paper urges the creation of a unified, all-embracing federal health agency with a cabinet secretary at its head, empowered to administer grants-in-aid to disadvantaged parts of the country, to conduct research in administrative needs, and to inspire adequate public health education in its broad sense, but not to coerce local governments into the practice of general curative medicine.

EMERSON, H. *Administrative Medicine.* *N. Y. State J. Med.* 39, 11:1055 (June 1), 1939.

Who Gets Good Prenatal Care—Three-quarters of the women in comfortable circumstances (in certain Michigan districts) received prenatal care, whereas three-quarters of those in the underprivileged group didn't. City women had better care than rural. This is not a surprising statistic to students of social sciences, but it may be useful evidence of an accepted assumption.

GODDARD, J. C., and PALMER, C. E. *Maternal Services in Michigan with Special Reference to Economic Status.* *Pub. Health Rep.* 54, 20:825 (May 19), 1939.

Genes and Viruses—Reporting to the informed laity upon the chemistry of the tobacco mosaic virus, the author gives an excellently clear picture of what science has discovered in that borderland where life begins. The paper will entertain and inform health workers, even those whose knowledge of biochemistry is elementary.

HUNT, W. R. "Whence Cometh Life." *Sci. Month.* 48, 9:550 (June 3), 1939.

Pros and Cons Re Blood Tests—Ten good reasons for requiring premarital blood tests for syphilis and four weak ones against. Five strong reasons for requiring blood tests during pregnancy or at delivery and none, of any kind, against. Score: both tests win!

KOLMER, J. A. *Laws Requiring Premarital and Pregnancy Tests for Syphilis.* *J.A.M.A.* 112, 23:2385 (June 10), 1939.

British Health and Medicine—It takes a conservative Briton to show how radical are we here in this wild and wooly America. The R. E. P. report quietly commends the proposal that medical services, like education, should be free to all. This writer urges that all health and medical services be unified and that the M. O. H. be put at the helm.

MILLIGAN, E. H. M. *Medicine and Public Health.* *Pub. Health.* 52, 9:266 (June), 1939.

England Studies Industrial Health Hazards—Some swell quotations from Ecclesiasticus introduce this British discussion of industrial hygiene. Listen to these sage comments upon: (hours) "every carpenter and workman that worketh night and day . . ."; (diseases) . . . "the vapor of the fire wasteth his flesh, and he fighteth with the heat of the furnace"; (repetitive work) "so doth the potter sitting at his work and turning the wheel about with his feet; who is always carefully set at his work, and maketh all his work by number"; (housing) . . . "and they shall not dwell where they will nor go up and down."

MUNRO, D. *Industrial Health Research.* *J. Roy. San. Inst.* 59, 12:717 (June), 1939.

Statesmanship in Public Hygiene—It is devoutly to be hoped that every complacent health worker—and others too—will take this paper into his little corner to ponder over with open mind.

The temptation to quote many of the arresting statements of facts that we all should know is well-nigh irresistible.

PARRAN, T. Health Needs of the Nation. Pub. Health Rep. 54, 22:919 (June 2), 1939.

Three Dimensional Graphs—Acetone vapor inhaled by guinea pigs affects temperature and respiration as concentration increases. The findings of this study will be of greatest moment to industrial hygienists, but all health educators—and what health worker isn't—will be interested in the three dimensional graphs which reveal these findings.

SPECHT, H., *et al.* Acute Response of Guinea Pigs to the Inhalation of Dimethyl Ketone (Acetone) Vapor in Air. Pub. Health Rep. 54, 22:944 (June 2), 1939.

Dose To Be Taken Every Hour—We are pleased to assume that American plumbing is the wonder of the world. A blaster of pet delusions reminds us of some of the water-borne disease outbreaks that have resulted because we are so well satisfied with ourselves and our plumbing.

STEARNS, M. M. The Hazard of Faulty

Plumbing. Survey Graphic. 28, 6:382 (June), 1939.

Hypertensive Arterial Disease—Here is an excellent discussion of the predisposing and the provoking factors that produce high blood pressure. Worrying, ambition, and inability to relax, traits that contribute to fatigue, predispose. Infections and numerous poisons provoke. The disorder is controllable rather than curable. Periodic examinations are needed to discover it early enough for hopeful treatment.

STIEGLITZ, E. J. High Blood Pressure. Sci. Month. 49, 1:35 (July), 1939.

T. B. in the Teens—Bed rest alone does not modify the spreading of tuberculous lesions in youngsters in the second decade, nor does it reduce the mortality. Therapy doesn't effect the mortality in advanced lesions. The prognosis of soft early lesions is uncertain for ten years. Health educators should realize the import of these findings even though they are to continue to teach that early discovery means early recovery.

ZACKS, D. Pulmonary Tuberculosis in the Second Decade of Life. Am. Rev. Tuberc. 39, 6:683 (June), 1939.

Previewing Pittsburgh's Science Centers

BUSTLING Pittsburgh, scene of the 68th Annual Meeting of the American Public Health Association in October, is a world center of chemical, engineering, and medical research. Not only is it the home of five institutions of higher learning and 38 hospitals, but also it boasts dozens of industrial laboratories in which new trails are blazed in technology, speeding the forward march of man.

The Committee on Scientific Trips has surveyed the rich field for tours and has made a comprehensive selection of the institutions, plants and laboratories for inspection by organized large groups of convention guests. In addition to the official tours, members will be able to make their own special arrangements to visit other local points of individual interest.

But meanwhile, the Publicity and Scientific Trips Committees will endeavor, in some small way, to give delegates a "preview" of points to be covered in scientific trips.

Air Hygiene Foundation—This organization represents a collective, scientific effort upon the part of some 250 industrial concerns for the advancement of industrial health. The Foundation, a non-profit corporation, maintains its headquarters and a Multiple Fellowship at Mellon Institute. It also makes research grants to the Saranac (N. Y.) Laboratory, Harvard School of Public Health, and University of Pennsylvania for studies and investigations in industrial hygiene. For instance, the Foundation recently issued a report to its member companies on the results of an X-ray research. Companies large and

small, in all lines of the "heavy" industries, have joined in this combined effort upon the part of employers in behalf of employee health.

Convention guests will have the opportunity of learning in detail about the work of the Foundation through its exhibits at Mellon Institute and at Convention Headquarters.

Aluminum Cooking Utensil Company—The New Kensington works of the Aluminum Company of America is the largest aluminum cooking utensil plant in the country.

The Aluminum Company had its origin in the Pittsburgh Reduction Company, which was founded in 1888 for the purpose of manufacturing aluminum by the Hall process. For several years it occupied a location on Smallman Street, Pittsburgh. Later it was moved to New Kensington, 18 miles up the Allegheny River.

The New Kensington plant is principally known for the manufacture of aluminum cooking utensils. In addition to the manufacture of such articles, visitors will see the rolling of aluminum sheet.

After the guests have completed their tour through the cooking utensil mill, they will be escorted to the Aluminum Research Laboratories, also located in New Kensington and noted as the largest aluminum research laboratories in the world.

Then the guests will have an opportunity to see, at close range, the world's most powerful testing machine, which, it is hoped, will be in operation by October 17.

Large extrusion presses make mold-

ings, trim, and other architectural shapes. This is a most interesting operation. A billet of aluminum is placed in the presses back of a die, and the pressure from the presses force the

aluminum through the die in any desired shape. The metal comes out of the press like tooth paste from a tube. Strong aluminum alloy sheet also is made here. This is the sheet that goes

New universal unit for the manufacture of aluminum bottle closures. The caps are first blanked from sheet (upper right), then conveyed to units for trimming and beading. Liners are inserted, and the caps are carried on belts to the inspectors (lower left), who examine both inside and outside of each cap. The machine is capable of producing up to 5,000 finished pieces an hour.

into the manufacture of airplanes and other structures where high strength combined with lightness is essential.

Great activity is to be found in the seal mill, where bottle caps and closures are made for innumerable products. Another important division is the foil mill, where aluminum foil is made for such purposes as milk bottle caps, wrappers for butter, cheese, tobacco, cigarettes, chewing gum, and candy. This foil can be colored, printed, and embossed, so that thousands of attractive patterns are available.

These commodities give some indication of the widespread use of aluminum, which, in a little more than fifty years, has gone from a laboratory curiosity to a material which is fourth in point of volume used among all metals.

City Filtration Plant—The city filtration plant is located in Aspinwall,

a suburb of Pittsburgh, about 8 miles from the city limits. It consists of 60 acres of filter beds all underground. The only surface indication of any activity is the general office and the pumping station along the river bank nearby. The water is pumped from the Allegheny River to a settling basin where the heavier impurities are deposited. It then flows by gravity to one of sixty filter rooms each approximately one acre in area. These rooms are about 10 feet high, with a concrete roof, over which is a 3 foot layer of soil. The floor of the room consists of a layer of sand several feet thick through which the water passes. After the water has passed through, the top two or three inches of sand are removed and washed to remove impurities, and then redeposited on the floor.

The filtered water flows by gravity

A dust determination in the course of a study by Air Hygiene Foundation.

back to the pumping station at the river bank, and it is then pumped to the Highland Park reservoir several miles distant for distribution throughout the city.

H. J. Heinz Company—The plant we will visit is the largest food products manufacturing establishment of its kind in the world. Its "57" varieties are used on millions of tables both in this country and in foreign lands.

Uniformed guides will conduct the group through the plant, showing visitors the preparation, closely supervised, of vegetables and fruits for canning and preserving. Great care is taken to insure the purity and quality of Heinz products.

Visitors will see the bottling depart-

ment for pickles. Here the pickles are graded, sorted, and bottled without ever being touched by human hands. Pickles are all bottled by hand labor, but the girls use wooden forks and spoons to handle the food.

The Heinz plant also has its own can manufacturing department. Machines cut, trim, roll, and form the metal, and then seal the bottom of the can, all in one operation.

Hospitals in the Pittsburgh Area—In addition to tours to industrial research laboratories and plants, arrangements are being made for a series of visits to various hospitals, particularly to those in which research is being conducted on public health problems.

Jones and Laughlin Steel Corpora-

Quality control is constant. The testing begins with raw materials for only the choicest are used. The preparation of foods is under scientific control. Heinz scientists are constantly looking for new and better ways to prepare food.

tion—The 96 inch continuous strip mill of the Jones and Laughlin Steel Corporation has been in operation a little over 2 years. It is located on a site of more than 23 acres between the Monongahela River and Second Avenue not far from the business section of Pittsburgh. It extends along the river for a little less than one-half mile.

Slabs for the mill are furnished from the new blooming mill installed directly across the river. Railroad cars of special design are provided to transport the hot slabs across the river.

The slab is passed into one of three continuous heating furnaces at temperatures of 2,150–2,250° F. It then passes to the hot mill where the rolling begins; it is reduced in thickness and

the ultimate width of the finished product is established. At the end of this operation the slab is cut into sheets or rolled into coils.

In this mill there are also a blue annealing department, coil pickling building, cold rolling mill, box annealing furnaces, cold finishing operation, and a galvanizing department. This galvanizing unit is set up to handle sheets up to 60 inches wide and 180 inches long. Black sheets are given a coating of hot zinc and carefully inspected by trained operators.

Mellon Institute—This institution was founded in 1913 by Andrew W. Mellon and Richard B. Mellon to provide qualified research workers with facilities for investigating thoroughly

Some of the most important finishing operations of the J. & L. 96 inch continuous strip mill take place in the cold rolling department. In this department, the strip and sheets rolled on the hot mill are given another rolling or reduction which imparts to them the finest surface finish and the proper physical characteristics. Much of the steel rolled on this mill will ultimately be formed into automobile bodies, air conditioning equipment, stoves, refrigerators, and such other products which require highly finished surfaces. The mill above is the 93 inch three tandem, four-high cold rolling mill.

Activities in the biochemical laboratory of the Meat Merchandising Fellowship at Mellon Institute, following experimental tenderizing involving special attention to enzymes.

important problems of pure and applied science. The Institute is primarily concerned in carrying on broad studies of post-doctoral character supported by persons or organizations interested in these fields of research.

The Institute's many investigations in the realm of pure science include studies on urban smoke abatement and industrial dusts, a comprehensive research on sleep, an investigation of the cause and prevention of dental caries, a project to find a better way to diagnose tuberculosis in its early stages, and a search for new compounds of value in treating pneumonia.

The industrial research of the insti-

tution is organized on a contract basis. The problem is set by a person, firm, or association, the scientific worker is engaged by the Institute, and an Industrial Fellowship is assigned for a period of at least one year. Each incumbent of an Industrial Fellowship is given the broadest facilities for accomplishing a definite piece of research; all results obtained by him belong exclusively to the donor of the Fellowship. Only one investigation is carried out on a particular subject at any one time, and hence there is no duplication of the research activities of the Fellowships in operation.

At present 80 Fellowships are active,

Courtesy of U. S. Bureau of Mines

This is a rock dusting machine at work in a mine "spraying" limestone dust which helps prevent dust explosions. Limestone is an inert dust, not regarded as harmful to health.

A view of the plant of the Mine Safety Appliances Company.

requiring the services of 240 scientists and engineers. During the 27 years since the foundation of the institution nearly 4,000 American companies have been served on problems ranging from glass and steel to food and textiles. The organization has evolved many novel products and processes, some of which have resulted in the formation of entirely new industries. Since 1911 more than \$13,000,000 has been contributed to the Institute by Industrial Fellowship donors.

In May, 1937, the Institute dedicated its new building, an imposing edifice whose most distinctive architectural feature is a colonnade of massive monolithic columns. The cubage of the structure is 6,500,000 cu. ft. It is one of the most beautiful and best equipped research laboratories in the world.

Tours through the building will cover all essential features of the institution, including its beautiful general rooms, its excellent technical library of 16,000 volumes, its efficient laboratories, and its engineering and development division. The trip will be made under trained guides who will describe in detail the operating principles of the Institute as well as the various research projects that are in operation.

Mine Safety Appliances Company—This is the largest manufacturing plant in the world devoted to the production of safety equipment. Originally founded to supply safety devices to the mining industry, it has pioneered in the development of a wide line of apparatus for general industrial safety. Much of this equipment is of considerable interest to public health officials, the medical profession, and specialists in the industrial hygiene field.

Gas and dust instruments form an interesting group of MSA products. By means of these instruments flammable or toxic gas concentrations can be detected and in some cases recorded.

The Westinghouse "Atom-Smasher" with which research physicists conduct experiments at the East Pittsburgh Laboratories in the field of nuclear physics.

Most of the long vehicular tunnels in this country use MSA instruments to sample continuously and control the carbon monoxide concentration. The MSA dust instruments and equipment, although on the market for only a short time, have found ready acceptance in mines and plants for the determination of dust in the atmosphere.

During the last few years the MSA Research Laboratories have made a study of silicosis and other respiratory diseases and means of protection against them. The result of this work is the MSA Comfo Respirator, the first dust respirator officially approved by the U. S. Bureau of Mines.

First aid training of mine and industrial workers has become quite common today, and MSA First Aid Equipment has gone hand in hand with the movement; special pocket packets, first aid cabinets of all kinds, stretchers, burn treatments, finger bandages, etc., are offered. One whole floor of the MSA plant is given over entirely to the manufacture of this type of material.

Other MSA equipment includes gas masks, breathing apparatus, head and eye protectors, and safety clothing.

Experimental Mine, U. S. Bureau of Mines—Thirteen miles from Pittsburgh is the Experimental Mine and Explosives Testing Station of the U. S. Bureau of Mines.

When the Bureau of Mines was organized in 1910, one of the important lines of investigation was the explosion of coal dust which had wrecked so many mines and killed so many men. To simulate actual conditions a tract of land underlaid with an undeveloped coal deposit was procured and the Experimental Mine was started.

The Mine consists of twin tunnels or entries driven in the coal for a distance of 1,300 feet, and two side entries in which rooms have been driven. Here actual explosions of coal dust are set off to show that rock dust is the most reliable means of preventing and controlling coal dust explosions. Here also explosives are tested for their value and permissibility in coal mine use.

Westinghouse Electric and Manufacturing Company—The Westinghouse Electric and Manufacturing Company is one of the most prominent in the electrical machinery field. Its products

are widely used in all parts of the world. The company's plant at East Pittsburgh occupies approximately 14,-000,000 square feet and employs many thousands of people.

The public utility industry is dependent on Westinghouse Electric for machinery for production, transmission, and utilization of electric power. Besides this heavier equipment the company also produces a complete line of electrical appliances for home use.

The East Pittsburgh plant manufactures a plastic insulating material known as Micarta, which has found application in many other industries, such as greaseless bearings, tunnel linings, and in place of wood.

The research department has pioneered in the field of electricity and radio and now has its own four story building entirely separate from the rest of the plant. This department is now conducting an extensive search in radio-activity and the structure of the atom. The company is noted for its work in industrial hygiene. It maintains extensive medical facilities which include an industrial hygiene laboratory.

The Scientific Program

68th Annual Meeting—Pittsburgh

THE Pittsburgh Annual Meeting, the 68th, lies just ahead.

The Section Secretaries and the Program Committee are now ready, after weeks of preparation and planning, to announce the results of their efforts in program building. Their aim has been to present to the health workers who will gather in Pittsburgh the most significant and promising of the newer developments in health services for the public and to bring these selected topics forward under the best possible auspices.

The program has been developed primarily around the interests of the ten Sections of the Association. There are in addition attempts at general orientation with the contemporary public health scene and experimental reconnoiterings in borderlands not yet officially ceded to a public health protectorate.

A resumé of the program is given here in lieu of the usual listing of subjects and speakers.

ADVANCE MEETINGS

While the dates of the Annual Meeting are announced as October 17-20, the convention actually gets under way on Sunday morning, October 15, with the opening of the Sixth Institute on Public Health Education. Its theme is "Health Education for Three-thirds of a Nation." Dr. Ira V. Hiscock is Chairman and he has assembled a faculty representative of the most progressive thinking and performance in the field of mass education for

health. He is assisted by Drs. Gruenberg, Kleinschmidt, Galdston, Patterson, Gebhard, Bauer, Cornely, Otto, Baumgartner, Shepard, Derryberry, Halverson, Walker, Morgan, Turner, and Leavell; by Messrs. Grimley, McCandless, Widdemer, Resnick, Dent, Marquette, and Broughton; and by Miss Grout, Miss Connolly, Miss Shaw, Miss Strachan, Miss Harris, and Miss Davis.

Small discussion groups are emphasized on such subjects as the spoken word, the radio, the newspaper, printed matter, exhibits, motion pictures, personal contacts and visual methods, program planning, school health education. There is a general session on how to reach professional, lay and student groups; one on how to appraise health education content and materials; one on organizing a coördinated health education program.

The Institute runs all day Sunday, all day Monday, and Tuesday morning. It is open to anyone engaged in or interested in health education. The registration fee is \$3.00 for Association members and \$6.00 for all others. The complete program is available on request to the Association office.

The International Society of Medical Health Officers will sponsor an Institute for Health Officers on Monday, October 17, with morning and afternoon sessions devoted to informal discussion of practical administrative problems. They join the students and faculty of the Health Education Institute at luncheon, and they have

planned a dinner for that evening with accent upon fun and sociability.

Five Conference groups will meet on Monday: State Laboratory Directors, State Sanitary Engineers, Municipal Public Health Engineers, Directors of Local Health Service and State Directors of Public Health Nursing.

The Association of Women in Public Health will hold a meeting Monday morning to consider the opportunities open to women planning a public health career. This will be followed by a luncheon, open to the public, with a well known newspaper man and an outstanding educator as speakers.

The National Organization for Public Health Nursing is joining with the American Public Health Association at its Annual Meeting, celebrating this event with a dinner on Monday evening. Dr. Winslow presides and Katharine Tucker speaks on "Preparation for Public Health Nursing—How, Where, When?"

The American School Health Association must be listed among advance meetings because its first and second sessions are held on Monday, although it continues throughout the week with joint meetings with Association Sections, sponsors a luncheon session on tuberculosis on Thursday, a session on school health policies on Thursday afternoon, and winds up on Friday morning with a summary of the special contributions of the 68th Annual Meeting to the school health program.

This Association's Monday afternoon program offers J. Louis Neff speaking on medical resources for the care of school children and Mellie F. Palmer, R.N., with the provocative title "Coöperative-Planning—A Dynamic for School Nursing." The Monday evening meeting presents Dr. B. B. Bagley, Dr. Fredrika Moore, and Dr. Helen A. Cary. Dr. Bagley answers the question "How can the state department help improve school health

procedures?" Dr. Moore indicates what should be attempted in school health work on a limited budget and Dr. Cary explains the part of the school physician in effective follow-up.

GENERAL SESSIONS

Six opportunities for entire Association participation are provided this year with programs that cut across all Section boundaries and that are of interest and concern to every member and guest.

Two evening general sessions are scheduled. On Tuesday evening, Dr. Edward S. Godfrey, Jr., will present his Presidential Address. The second speaker, Dr. Milton J. Rosenau, inaugurates the Delta Omega Lectureship with a philosophical essay entitled "New Lamps for Old." The second evening general session will be held on Thursday in the form of the Annual Banquet.

A session on Medical Care has been arranged for Wednesday afternoon with discussions on medical care as a welfare function and as a public health function.

On Wednesday, Thursday, and Friday mornings, Section meetings will be dismissed at 11:15 to permit attendance at general sessions of one hour duration. The subjects considered by the Program Committee of sufficient importance to engage the attention of all delegates are "The American Way as Seen from Abroad" with contributions from distinguished visitors from overseas, "Cancer," and "Professional Education."

JOINT SESSIONS

The Child Hygiene and Public Health Nursing Sections and the American School Health Association come together to consider the physical and emotional development of the adolescent with the implications that each has for the general health program and the

school health program. William Greulich, Ph.D., Caroline Zachry, and Lawrence K. Frank are the speakers, with the nursing interests represented by Hortense Hilbert, R.N.

The Child Hygiene Section figures also in a joint meeting on dental health with the American School Health Association and the Oral Health Group and further with the Public Health Education Section and the American School Health Association in a session on "The Educational Psychology Underlying the Motivation of the Individual." This is attacked at the elementary school level by Dr. James F. Rogers, at the secondary school level by Philip L. Riley, and at the adult level by Raymond H. Greenman.

The Health Officers and the Industrial Hygiene Sections sponsor a symposium on illness in industry and its control. Dr. C. H. Kibbey tells of a quarter century with an industrial health department; Dr. Anthony J. Lanza talks on tuberculosis in industry; Dr. Clarence D. Selby shows how industry can approach adult health problems, and Dr. Carl A. Wilzbach contributes a paper on the control of syphilis in industry.

The administrators collaborate with the educators in one session, the Health Officers represented by Dr. I. C. Riggins and Dr. George T. Palmer, the Public Health Education Section by Professor C. E. Turner, Savel Zimand, and Dr. Leona Baumgartner.

Pneumonia receives attention at the hands of the Health Officers and the Epidemiology Sections in a symposium in which Dr. Lloyd D. Felton, Dr. Wheelan D. Sutliff, Dr. Wilson G. Smillie, and Dr. Ernest L. Stebbins are taking part.

Miscellaneous problems which depend for their solution upon coöperation between the health officer and the public health engineer, such as hygiene of swimming, restaurant sanitation, and

automatic control of pasteurization, are considered in a joint session of the Health Officers and Public Health Engineering Sections. The speakers are Dr. H. Marshall Long, H. H. Wagenhals, A. W. Fuchs, and Sol Pincus.

The engineers hold their customary joint session with the Conference of State Sanitary Engineers. The subjects include training of water works operators, standards for bathing places, sanitary land-fills, the National Plumbing Laboratory, and functions of public health engineering personnel, with speakers as follows: Anselmo F. Dappert, Warren J. Scott, Lewis V. Carpenter, Francis M. Dawson, and Roy J. Morton.

A symposium on engineering problems in industrial hygiene involves the engineers and the industrial hygienists. B. F. Postman discusses exhaust ventilation and occupational exposures; J. M. Dalla Valle, M.D., voices the principles of industrial sanitation; J. M. Graves, M.D., suggests methods for integrating industrial hygiene with local health service, and W. Scott Johnson proposes an administrative approach to the engineering phases of industrial hygiene.

The Laboratory and Food and Nutrition Sections combine once for a consideration of food poisoning with such experts on the platform as Fred W. Tanner, T. D. Nunheimer, and Glenn G. Slocum, and again in a session on dairy products where the methylene blue and the Resazurin tests are compared for results, constant temperature incubation in milk control work is stressed, and pasteurization efficiency is examined. Lawrence Little, Robert S. Breed, Ph.D., Harold W. Leahy, Harry Scharer, and E. H. Parfitt appear on this program.

Gastroenteritis is given an entire session by the Laboratory and Epidemiology Sections. The newer knowledge of bacillary dysentery and other

intestinal infections is summarized by Joseph Felsen, M.D. An outbreak of Shiga dysentery and outbreaks of gastroenteritis of unknown etiology are described respectively by Berneta Block, M.D., and Millard Knowlton, M.D. Albert V. Hardy, M.D., has a paper on the "Newcastle Dysentery Bacillus" and Marion B. Coleman one on differentiation and identification of bacillary incitants of dysentery.

The Food and Nutrition and Child Hygiene Sections and the American School Health Association spend a half-day on the subject of nutrition. William Schmidt, M.D., George M. Wheatley, M.D., Lynda M. Weber, and C. C. Hudson, M.D., are among the names on this program. Their presentations deal with the appraisal of nutritional status by newer medical methods, the care of undernourished children, teaching nutrition in high schools, and the school lunch.

THE SECTION PROGRAMS

The 12 joint and 6 general sessions already described and the many advance meetings would seem to offer a full week's work for the avid seeker after knowledge. The independent meetings of the ten Sections provide competition of high order, however, and offer opportunities for the specialist to get down to fundamentals.

Health Officers. "Promising Additions to Health Department Programs," "Personnel Problems," and "Venereal Diseases" are the titles of the three independent sessions of this Section.

In the first, Drs. J. N. Baker, K. E. Miller, George C. Ruhland, and Ralph C. Williams discuss respectively farm and home accidents, advertising control of foods, drugs, cosmetics and devices, hospitals in a public health program, and medical care plans for low income farm families.

In the second, prevailing employment policies in health departments are

summarized by Dr. M. V. Zeigler, personnel administration under civil service is described by Dr. George T. Palmer, lessons that may be learned from personnel administration in industry are pointed out by S. J. Fosdick, and Dr. Mayhew Derryberry reports on a study of educational qualifications of staff members in health departments.

The symposium on venereal diseases has as its contributors Dr. Nels A. Nelson, Dr. John H. Stokes, Mary Hooke Goodwin, Dr. P. S. Pelouze, and Dr. Theodore Rosenthal. Their subjects, in the order of the speakers listed, are: Why don't we stamp out gonorrhea?; A study of consultation on syphilis by correspondence; The advantage of the family clinic in the prevention and control of syphilis; The control of gonococcal infection and syphilis among domestic servants.

Laboratory. The first session is given over to reports of Standard Methods Committees. The Laboratory Section is the breeding ground for some of the most significant of the Association's work and these reports of research accomplished and in progress have important implications for all health workers. They include water and sewage, dairy and food products, diagnostic procedures and reagents, biology of the laboratory animal, frozen deserts, biological products, and shellfish.

One session is devoted to the newer venereal diseases. Dr. E. S. Sanderson describes the laboratory aspects of chancroid, granuloma venereum and lymphogranuloma venereum, and Dr. Fred Wise discusses and illustrates the differential diagnosis of these diseases. Dr. Joseph R. D'Aunoy gives detailed consideration to the last named, and Dr. Robert B. Greenblatt takes the broad view in a paper on aspects of all the newer venereal diseases.

The biology of the laboratory animal receives attention at the hands of Dr. R. G. Daggs, Dr. Gregory Pincus, Dr.

Paul B. Sawin, Dr. Paul A. Moody, Dr. Norman J. Pyle, Captain Ralph W. Mohri, and Lt. Col. Raymond A. Kelsner.

Two sessions of miscellaneous titles complete the Laboratory program. The papers deal with reasonably priced incubators, rabies, gonococcus carriers, effect of chemical antiseptics on phagocytosis, heat resistance of streptococci, oral contamination of drinking glasses, slow lactose fermenting coliform organisms, *E. typhosus* in soils, laboratory diagnosis of enteric diseases, and toxicity of basic fuchsin for certain diseases. The speakers are: Lt. Col. A. Parker Hitchens, Dr. Charles N. Leach, Dr. Charles M. Carpenter, Dr. Henry Welch, Dr. Edward C. Rosenow, Leo Dick, Dr. Charles A. Stuart, Dr. Paul J. Beard, Dr. Joseph A. Kasper, Catherine Mayfield, and Cassandra Ritter.

Vital Statistics. Four independent meetings containing a total of twenty papers and reports reveal the present interests of statisticians. Five papers are grouped in a symposium on the coördination of vital statistics with the expanding programs for social welfare. They cover record keeping for venereal diseases; hospital morbidity reporting; statistical needs of maternal and child health organizations as related to county and state programs; the relationship of the work of the Social Security Board to that of the state, city and local registrars, and the broader aspects of the coördination of vital statistics with the expanding programs for social welfare. Lida J. Usilton, Dr. Helen Jeter, Dr. Edwin F. Daily, Willard C. Smith, and Dr. Lowell J. Reed are the speakers.

Other topics and speakers are: Exhibit technics in vital statistics at the New York World's Fair, Jacob Baar; Publicity in promoting registration of births and deaths, Dr. Martin B. Woodward; Educating medical students

and others concerned with registration data, I. C. Plummer; Reflections on fatality rates for reported cases of tuberculosis, Dr. Gaius E. Harmon; Evaluation of the Massachusetts state-aided cancer clinics, Eleanor J. MacDonald; Tabulating associated causes of death, Theodore A. Janssen; Experiences with the new forms of certificates, Thomas W. Chamberlain; Reliability of statistics on cause of death, Robert G. Webster; Plans for the 1940 census, Dr. Leon E. Truesdell; and Utilizing vital statistics in the public health program, Dr. Floyd P. Allen.

Public Health Engineering. The many joint meetings with which the engineers are concerned this year have limited their individual meetings to two. The Committees on Sewage Disposal and Shellfish, Chairmanned respectively by Langdon Pearse and L. M. Fisher, are reporting. Some observations on sanitary land-fills are made by Lewis V. Carpenter; Measures instituted for the control of *Aedes aegypti* are announced by James H. LeVan; A typhoid fever outbreak caused by "bootleg" oysters is reported by H. N. Old; The relationship of stream pollution abatement to Pittsburgh's water supply and health is traced by Dr. Chester F. Drake; The water pollution research program of the U. S. Public Health Service is reviewed by John K. Hoskins; and Certain aspects of governmental policy on stream pollution abatement are discussed by Dr. Herman G. Baity.

The Stag Dinner, social event of the meeting for engineers, will be held on Wednesday evening.

Industrial Hygiene. This Section is celebrating the 25th anniversary of its founding with a Silver Jubilee Dinner on Wednesday evening which promises to be a high spot socially, historically, and scientifically.

A luncheon session, at which Dr.

Henry Field Smyth, Sr., and Dr. Henry Field Smyth, Jr., will present reports of the Committees on Industrial Anthrax and Volatile Solvents, is of interest.

A symposium on field methods for rapid determination of air contaminants, with Dr. H. H. Schrenk specializing on dusts, Philip Drinker on vapors, and F. A. Patty on gases, is scheduled.

Other speakers listed are J. J. Bloomfield, Glenn S. Everts, Dr. Shirley W. Wynne, Dr. Robert H. Flinn, Theodore F. Hatch, and M. F. Trice. Their names follow the subjects: Address of the Chairman, Industrial hygiene for the smaller plant, Hearing and noise in industry, The dust problem in the pottery industry, The control of dust in rock drilling operations, and The dust hazard and its control in the foundry industry.

Food and Nutrition. Three individual sessions and a luncheon are planned.

Packaging of food products is approached from three standpoints. Dr. J. Raymond Sanborn takes the microbiological examination and standardization of paper wrappers and containers; Dr. Evan Wheaton the bacteriological problems relating to foods packed in paper containers; and the Committee on Milk and Dairy Products, Merrill J. Mack, Chairman, makes its report on the sanitary aspects of packaging milk and milk products.

Foods frozen in cold storage lockers and farm freezers are considered by the Committee on Foods, Dr. Donald K. Tressler, Chairman.

The new Food, Drugs and Cosmetic Act and its public health implications is the contribution of Walter S. Frisbie; Dr. Abraham Lichterman has a paper on trichinosis and its control; and William G. Walter one on distintegration methods for the bacterial examination of meat.

Milk figures prominently in several

presentations. Nutritive and economic values of skim milk, economical milk products in human nutrition, and recent investigations of goat's milk are three papers to be read respectively by J. S. Abbot, Dr. Marietta Eichelberger, and Dr. Arthur K. Besley. The Burri Smear culture technic is described by Dr. B. W. Hammer.

The Oral Health Group as well as the Food and Nutrition Section will be interested in Dr. Mark Elliott's study on retardation of dental caries by dietary supplement and Dr. C. G. King's work on the effects of vitamin C intake upon tooth injury produced by diphtheria toxin.

Helen N. Church surveys the public health nutrition service in the United States; Dr. Walter H. Eddy asks what evidence there is of vitamin deficiency in the diet of the American people; Dr. Wilton L. Halverson talks on nutritional deficiencies in community groups with particular reference to vitamin B; and Dr. Morris Ant on the interpretation of nutritional factors in treating disease.

The luncheon session is devoted to reports of committees.

Child Hygiene. Experiences in rendering an obstetric delivery service in a rural area, stillbirths and neonatal deaths, a health department birth control program, a study of bacillary dysentery in rural areas, promotion of mental health, the development of a health education program, and advances made in the Federal program for the care of crippled children are subjects the Child Hygiene Section will cover in its two independent sessions and a luncheon meeting. The speakers are not yet announced, except for Dr. James Watt, who will present the dysentery paper.

Public Health Education. This Section announces frankly that its first session has been arranged particularly for new workers in the health education

field. The subject is equally frank—A reëvaluation of health education media. The debunkers are: Philip S. Broughton, who takes Printed Materials, Effective and Otherwise; Kenneth W. Grimley, with Newspapers and Magazines—Is Health News Fit To Print? Sally Lucas Jean, on Visual Aid Advances; Dr. W. W. Bauer, with Public Meetings—Are They Worth While? and Joseph Ries, with The Health Educator on the Radio.

"Frontiers in Medical Research and Advances in Science as they pertain to Health Education" is the title of the second session. Chemotherapy, mental hygiene, virus diseases, nutrition, and school dental health education are selected for this special attention; and the speakers, in the same order, are Dr. Jesse G. M. Bullowa, Dr. Emerson North, Dr. Ralph S. Muckenfuss, Dr. C. G. King, and Dr. Florence B. Hopkins.

The status, plans, and policies of the Section will be discussed at a dinner meeting. One luncheon is scheduled with Dr. Owsei Temkin speaking on the subject "Health Education Through the Ages."

Epidemiology. Four individual sessions with a wide range of topics are planned. Dr. Harold W. Brown presents the problem of malaria mortality, and Dr. Harry Most presents studies on malignant malaria in drug addicts. Dr. Thomas B. Turner calls attention to the factors which influence the interpretation of discovery rates in syphilis.

There are addresses by Drs. Donald T. Fraser, William Grossman, J. A. Doull, D. G. Gill, Martin Frobisher, Jr., Ernest L. Stebbins, and G. Foard McGinnes on the important diphtheria carrier survey.

Drs. Miriam Brailey, George W. Weber, and L. L. Lumsden are responsible for three tuberculosis papers entitled respectively "A Study of Mortality in the Children of Tuberculosis

Households," "Tuberculosis in a Controlled Environment," and "Epidemiological Studies of Tuberculosis."

The epidemiology of "San Joaquin" or "Valley Fever" is described by Dr. Charles Edward Smith, of anthrax in North Dakota by Dr. John A. Cowan, and of three outbreaks of infectious jaundice by Dr. John J. Shaw. Jaundice in Detroit engages Dr. J. G. Molner; tick paralysis, Dr. R. B. Jenkins; and the modes of spread of respiratory infections, William F. Wells.

Public Health Nursing. The first of the two sessions on this program is devoted to reports of committees plus a discussion by Frances R. Pratt of the staff education programs for public health nurses developed by the North Carolina State Board of Health. The Committees reporting are: Relationships between official and non-official public health nursing agencies, Julia L. Groscop, Chairman; Industrial Nursing in and around Pittsburgh, Helen V. Stevens, R.N., Chairman; and Subcommittee on Public Health Nursing of the Committee on Administrative Practice, Marion W. Sheahan, R.N., Chairman. Brief reports of representatives of the Public Health Nursing Section on Association Committees are also scheduled.

The second session lists Reba F. Harris for a paper on coördination of educational programs for all health workers, Anna Heisler, R.N., and Beryl Lussow, R.N., presenting respectively the rural and city agency viewpoint on the continuous educational program which supervision of public health nurses is. Dr. Iago Galdston discusses "Changes in Public Health Nursing Functions as a Result of New Medical Discoveries."

Dr. Edward S. Godfrey, Jr., is the speaker at a luncheon session. His subject is "Relation of the State Division of Public Health Nursing to Local Agencies."

OTHER MEETINGS

During the week numerous administrative and technical committees and other groups will meet. Many are holding breakfast, luncheon, or dinner conferences. An event of special importance is the dinner of the Pennsylvania Public Health Association on Wednesday evening, to be followed by a meeting to which the public is invited. The speakers scheduled for this meeting are Dr. Henry F. Vaughan

and Dr. Arthur T. McCormack.

It is to be emphasized that the foregoing is a summary of the scientific program. For the sake of brevity, titles are shortened in most instances and sometimes rephrased. Names of collaborating authors are omitted. The final and official program, to be distributed at the Registration Desk in Pittsburgh, will give full credit to co-authors and will report titles accurately and completely.

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association, the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, providing such petition is received fifteen days before the Annual Meeting." The *Chairman* of the Committee is Dr. John J. Sippy, San Joaquin Local Health District, Stockton, Calif.

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Pittsburgh, Pa., will be elected for the three year term 1939-1942.

APPLICANTS FOR FELLOWSHIP

In accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Eligibility, and the Governing Council will take place between now and the time of the Pittsburgh Annual Meeting.

Health Officers Section

Joseph I. Linde, M.D., Health Officer, New Haven, Conn.

Laboratory Section

Natale Colosi, Ph.D., Director of Laboratories and Supt., Parkway Hospital, New York, N. Y.

Elizabeth J. Cope, B.S., Bacteriologist, Department of Health, Detroit, Mich.

George McL. Lawson, M.D., Dr.P.H., Professor of Preventive Medicine and Bacteriology, Department of Medicine, University of Virginia, Charlottesville, Va.

Stuart Mudd, M.D., Professor of Bacteriology, University of Pennsylvania Medical School, Philadelphia, Pa.

George T. Stevens, Director, Clinical Laboratory, U. S. Marine Hospital, San Francisco, Calif.

Vital Statistics Section

Sterling S. Cook, M.D., Dr.P.H., Chief of Medicine, Norfolk Naval Hospital, Portsmouth, Va.

Halbert L. Dunn, M.D., Ph.D., Chief, Division of Vital Statistics, Bureau of the Census, Washington, D. C.

Albert G. Love, M.D., Dr.P.H., Vital Statistical Division, U. S. Army, Washington, D. C.

John T. Marshall, Director, Division of Vital Statistics, Provincial Board of Health, Victoria, B. C., Canada

John R. Miner, Sc.D., Associate Editor, Mayo Clinic, Rochester, Minn.

Leonard V. Phelps, S.B. in P.H., Director, Bureau of Vital Statistics, State Department of Health, Montgomery, Ala.

Ruth R. Puffer, A.B., Statistician, State De-

partment of Public Health, Nashville, Tenn.
Franklin H. Reeder, M.B., Ch.B., State Registrar of Vital Statistics, State Health Department, Charleston, W. Va.

Lida J. Usilton, A.M., Senior Statistician, U. S. Public Health Service, Washington, D. C.

John M. Wheelis, Jr., M.D., Dr.P.H., Medical Officer, U. S. Navy, San Pedro, Calif.

Richard N. Whitfield, M.D., State Director of Vital Statistics, State Board of Health, Jackson, Miss.

Jacob Yerushalmy, Ph.D., Statistician, National Institute of Health, U. S. Public Health Service, Bethesda, Md.

Industrial Hygiene Section

Warren A. Cook, A.B., Division of Industrial Hygiene and Engineering Research, Zurich General Accident and Liability Insurance Company, Chicago, Ill.

Charles C. Dills, M.S., Industrial Hygiene Engineer, State Board of Health, Lawrence, Kans.

Henry F. Smyth, Jr., Ph.D., Industrial Fellow, Mellon Institute of Industrial Research, Pittsburgh, Pa.

Food and Nutrition Section

William F. Reindollar, Sc.D., Chief, Bureau of Chemistry, State Department of Health, Baltimore, Md.

Child Hygiene Section

Adrian L. Carson, Jr., M.D., Assistant Director, Bureau of Maternal and Child Health, State Department of Health, Richmond, Va.

Edwin F. Daily, M.D., Director, Maternal and Child Health Division, Children's Bureau, Washington, D. C.

Public Health Education Section

Claude W. Chamberlain, Ph.D., Supervisor of Health Education, State Department of Public Health, Springfield, Ill.

William W. McFarland, M.D., Executive Director, General Health Council, Pittsburgh, Pa.

Charles E. Shepard, M.D., Professor of Hygiene and Director of Student Health, Stanford University, Calif.

Public Health Nursing Section

Henrietta M. Adams, R.N., M.S., Associate Professor and Director of Nursing Education, School of Nursing, University of Washington, Seattle, Wash.

Kathleen M. Logan, R.N., Supervisor of Nurses, Rutherford County Health Department, Murfreesboro, Tenn.

Helen C. Manzer, R.N., Ph.D., Associate Professor of Education and Director of Curricula in Nursing Education, School of Education, New York University, New York, N. Y.

Frances C. Montgomery, R.N., M.A., Pro-

fessor of Public Health Nursing, College of William and Mary, Richmond, Va.

Dorothy Rood, Ph.D., Associate Professor and Director of Public Health Nursing, Loyola University, Chicago, Ill.

Beatrice Short, R.N., B.S., Superintendent, Indianapolis Public Health Nursing Association, Indianapolis, Ind.

Edith L. Soule, R.N., Director, Division of Public Health Nursing, State Bureau of Health, Augusta, Me.

Helen V. Stevens, R.N., B.S., Director, Public Health Nursing Association of Pittsburgh, Pittsburgh, Pa.

Unaffiliated

Fred L. Moore, M.D., C.P.H., Associate Professor of Preventive Medicine and Community Health, Long Island College of Medicine, Brooklyn, N. Y.

James L. Neff, Executive Secretary, Nassau County Medical Society, Mineola, L. I., N. Y.

George St. J. Perrott, M.A., Statistician, U. S. Public Health Service, Washington, D. C.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Samuel R. Berenberg, M.D., Medical Center, Greenbelt, Md., Director, Dept. of Public Health

Bryson E. Cox, M.D., 226 North 5th St., Coalinga, Calif., Health Officer and School Physician

W. W. Crook, M.D., Stone Bath House, Glenwood Springs, Colo., Garfield County Health Officer

Isbin S. Giddens, M.D., Millen, Ga., Commissioner of Health, Jenkins County Health Dept.

Harold W. Hackler, M.D., Poplar, Mont., Senior Physician, U. S. Indian service

Charles C. Hedges, M.D., Health Dept., Savannah, Ga., City-County Health Officer

James M. Hershey, M.D., D.P.H., Pouce Coupe, B. C., Canada, Director, Peace River Health Unit

John M. Hooper, M.D., Public Health District #1, Floydada, Tex., Director

Wilbur T. Little, M.D., 903 Macon Ave., Canon City, Colo., Fremont County Health Officer

John L. Reiger, M.D., Box 121, Craig, Colo., City-County Health Officer

Earl A. Rogers, M.D., Madison, Nebr., Medical Director, District Health Unit #2

Wyatt E. Royce, M.D., Box 747, Covington, Va., Health Officer

Wixom S. Sibley, M.D., U.S.P.H.S., 14th Ave. & Lake St., San Francisco, Calif., Assistant Surgeon

William O. Whitaker, M.D., Box 1, Creede, Colo., City-County Health Officer

O. F. Whitman, M.D., Box 193, Statesboro, Ga., Commissioner of Health, Bullock County Health Dept.

Laboratory Section

M. Elmer Christensen, B.S., 35 State Capitol, Salt Lake City, Utah, State Chemist

Bernice U. Eddie, M.A., Hooper Foundation for Medical Research, Medical Center, San Francisco, Calif., Instructor in Research Medicine

C. Virginia Fisher, Ph.D., Warner Institute, 113 W. 18 St., New York, N. Y., Bacteriologist

Donald M. Hetler, Ph.D., Montana State University, Missoula, Mont., Professor of Bacteriology & Public Health

Ruby S. Hirose, Ph.D., Wm. S. Merrell Co., Lockland Station, Cincinnati, Ohio, Biologist

Lois E. Hoar, B.S., Montana State Tuberculosis Sanitarium, Rt. 1, Deer Lodge, Mont., Laboratory Technician

Evelyn L. Kuehn, 303 N. Ewing St., Helena, Mont., Laboratory Technician, St. Peter's Hospital

Elizabeth Maltaner, B.S., 388 New Scotland Ave., Albany, N. Y., Associate Bacteriologist, Division of Laboratories and Research, New York State Dept. of Health

Mrs. Frances Martin, 318 Hickory St., Anacondo, Mont., Medical Technologist

Granville M. Neal, B.S., 23 Marden St., Cranston, R. I.

Arthur W. O'Donnell, B.S., 837-9 Ave., Helena, Mont., Serologist, State Board of Health

Edith M. Rich, M.S., Biology Dept., Trinity College, Washington, D. C., Teacher of Bacteriology

Walter A. Tschirgi, B.S., 516 W. Clev St., Bozeman, Mont., Research Assistant, Department of Bacteriology, Montana State College

Albert L. Vadheim, Jr., B.A., State Board of Health, Helena, Mont., Technician, Hygienic Laboratory

Julia Vinograd, M.D., 18-45 21 Road, Astoria, L. I., N. Y., Bacteriologist, Bureau of Laboratories, New York City Dept. of Health

Donald E. Warner, B.S., Box 339, Helena, Mont., Sanitary Inspector, State Board of Health

Vital Statistics Section

Lewis Conrad, B.S., State Board of Health, Helena, Mont., Fiscal Agent

Unaffiliated

George B. Davis, M.D., 29 Whitfield St., Guilford, Conn., Graduate Student, Dept. of Public Health, Yale Medical School
Charles T. Snyder, M.D., 1100 Park Ave., New York, N. Y.

DECEASED MEMBERS

Miss Grace Abbott, Chicago, Ill., Elected Member 1929
Roy R. Jones, M.D., Washington, D. C., Elected Member 1935

Harry A. Simrell, M.D., Stockton, Mo., Elected Member 1938

CLOSING DATE FOR ACCEPTING FELLOWSHIP APPLICATIONS

NOTICE is hereby given to any interested members that September 1 is the closing date for accepting Fellowship applications for 1939 election.

Eligible members wishing to apply for Fellowship this year should submit their completed applications as much in advance of this date as possible.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, when keyed, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y., identifying clearly the key number on the envelope.

POSITION AVAILABLE

The Board of Health of Tulsa, Oklahoma, will receive applications from trained and experienced physicians for the full-time position of Superintendent of Health. (See page 975.) Qualified applicants should communicate with Dr. Ned R. Smith, Oakwood Sanitarium, Rural Route 6, Tulsa.

POSITIONS WANTED

Physician, experienced in health administration of cities and states, will consider attractive opening in maternal and child health or health education. **A343**

Physician; M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; is available as venereal disease control officer. **A363**

Physician; M.D., Syracuse University; postgraduate studies in bacteriology and immunology; will consider position as health officer or epidemiologist. Has served as director of county health unit, director of industrial hygiene and medical statistics and venereal disease field survey officer. **A305**

Well qualified physician; M.D., Rush; M.S.P.H., University of Michigan; with three years' residence in tuberculosis, and special interest in venereal disease control; seeks responsible appointment. Excellent references. **A406**

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. **A355**

Physician; M.D., Vanderbilt University; Dr.P.H., Johns Hopkins; experienced as epidemiologist, health officer and professor of preventive medicine; seeks position as administrator or epidemiologist. **A397**

Physician, aged 30; M.D., University of Illinois; C.P.H., University of California; experienced as instructor in medicine and director of state division of epidemiology; desires position in communicable disease control or administration. **A399**

HEALTH EDUCATION

Health educator, with excellent background of teaching experience in schools; M.S.P.H., University of Michigan; wishes a position where skill with educational sound film projection and other recognized technics will be appreciated. **H405**

Young woman, with C.P.H. from Massachusetts Institute of Technology and broad experience in the health education field, consisting of consulting service to schools, in-service training of teachers, and health education coordination, desires position as health education coordinator or as a teacher of health education. **H428**

LABORATORY

Broadly experienced laboratory director with excellent background, now employed southern state, seeks responsible position in laboratory work or teaching of bacteriology, immunology and pathology. **L426**

Bacteriologist, aged 30, Ph.D., 1938; special experience and research in anaerobic bacteriology; experienced in hospital and out-patient laboratory work and in teaching; seeks position in commercial or public health laboratory. **L424**

Woman bacteriologist; B.A., Chemistry, 1933; 5 years' experience in experimental and practical therapeutics including animal work; desires position in public health field. **L394**

Bacteriologist and serologist, recently graduated from the University of Michigan with M.S.P.H., seeks position with promise. Willing to start modestly. **L425**

Bacteriologist, aged 33, with training in serology; for the past 4 years bacteriologist in charge, public health laboratory; will consider opening. **L427**

MISCELLANEOUS

Young woman physician, M.D., M.S., D.Sc., desires position in public health work or medical research, particularly in the field of pediatrics or child hygiene. Now resident in pediatrics. Several years research experience in parasitology and medical zoology. **C429**

Situations Open

ASSOCIATE PROFESSOR PUBLIC HEALTH—Physician in thirties with special training and experience in preventive medicine preferred; good research record advantageous; \$3,000-\$4,000; university medical school. 80-PH, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH PHYSICIAN—Eastern physician, experienced public health or administration; work entirely administrative; \$4,000. 81-PH, Medical Bureau, Pittsfield Building, Chicago.

SCHOOL PHYSICIAN—Recent graduate contemplating public school health service as life work; duties include some teaching and dispensary service for students; eastern university; \$200. 82-PH, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH PHYSICIAN—Southern college; enrollment averages a thousand, including faculty. 83-PH, Medical Bureau, Pittsfield Building, Chicago.

SCHOOL PHYSICIAN—Must be familiar with public health problems, eligible Washington licensure; excellent connection. 84-PH, Medical Bureau, Pittsfield Building, Chicago.

SCHOOL NURSE—Graduate nurse, preferably of mature years, for appointment in school enrolling principally boys of junior-senior high school grade from rural districts; duties light; must be Protestant. 85-PH, Medical Bureau, Pittsfield Building, Chicago.

SCHOOL NURSE—Exclusive school for girls, with average enrollment of 100; duties will include complete charge infirmary, some teaching and chaperoning; graduate nurse, 30-35, preferably Protestant, desired; location near eastern cultural center. 86-PH, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH NURSE—For combination appointment including care of children in small day nursery and visiting insurance policy holders in restricted area; hours 8-5; \$125, private office, car and car maintenance; must be certified. 87-PH, Medical Bureau, Pittsfield Building, Chicago.

SCIENCE INSTRUCTOR—Qualified to teach public health in school of nursing; 600-bed hospital; midwestern metropolis. 88-PH, Medical Bureau, Pittsfield Building, Chicago.

Situations Wanted

PUBLIC HEALTH NURSE—Particularly interested in executive position in clinic or public health field; graduate of teaching hospital; B.S. in public health nursing; graduate courses in public health at Western Reserve and Columbia; several years' executive experience in public health nursing; four years, director of large clinic; for further information, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

HEALTH EDUCATOR—Graduate nurse and B.S. degrees; social service certificate; three years' experience in social service; four years, industrial nursing; ten years, director of a health council; for further details, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

BACTERIOLOGIST—B.A., eastern school; C.P.H. and Ph.D. (bacteriology), Yale University; has done considerable research; four years, bacteriologist and research technician, public health laboratories; desires appointment in public health laboratories; for further details, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH PHYSICIAN—Desires connection; M.D., Virginia; several years' successful private practice; ten years' public health work during which time he has been promoted continuously; excellent reason for relocating; for further details, please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

NEWS FROM THE FIELD

ADVISORY COUNCIL ON MEDICAL EDUCATION

AN Advisory Council on Medical Education came into being on June 24 in Chicago, when 11 national organizations concerned with the training of physicians to meet the present day needs of medical care for the country recognized the necessity for some central representative agency to make medical training more effective. Willard C. Rappleye, M.D., Dean of the Faculty of Medicine at Columbia University College of Physicians and Surgeons, was elected President. Dr. Rappleye pointed out that this organization for the first time brings together various national bodies dealing with all phases of the training and licensing of physicians, beginning with the preparatory college work and including medical education, hospital internship, residency, licensure, and graduate training for specialization.

The American Public Health Association is represented on the Advisory Council on Medical Education through W. S. Leathers, M.D., Dean and Professor of Preventive Medicine and Public Health, School of Medicine, Vanderbilt University, Nashville, Tenn., and Chairman of the Committee on Professional Education of the American Public Health Association. Other organizations represented are the Association of American Medical Colleges, the American Hospital Association, the Catholic Hospital Association, the American Protestant Hospital Association, the Association of American Colleges, the Federation of State Medical Boards of the United States of America, the Advisory Board for Medical Specialties, the National Board of Medical Examiners, the American College of Physicians, the American College of Surgeons, the Association of American

Universities, and the American Association for the Advancement of Science, Division of Medical Sciences.

Among the problems considered by the Council at its meeting were those of educational standards for the hospital internship, adequate training for the specialist, sound programs for the continued education of physicians in practice, modifications in college preparation for medical studies, the simplification of the procedure for licensure in the 48 separate states and the status of training of graduates of foreign medical schools.

DEDICATION OF AMERICAN MUSEUM OF HEALTH, INC.

ON Saturday, June 17, 1939, many physicians, public health officials, medical scientists, educators, and other prominent persons participated in ceremonies dedicating the American Museum of Health, Inc. The exercises were held in the Hall of Man of the Medicine and Public Health Building at the New York World's Fair.

With generous support from the Carnegie Corporation of New York, the Rockefeller Foundation, the Oberlaender Trust, and the major life insurance companies, this Museum has created or acquired most of the exhibits in the Medicine and Public Health Building. At the end of the Fair period, it will add to and maintain these displays in a permanent health teaching center in the City of New York. Coöperation in securing a building to house its activities has been assured by several public officials, including Mayor Fiorello H. LaGuardia, a director of the Museum.

Among the speakers at the dedication ceremonies were: Abel Wolman, Dr. Eng., Edward S. Godfrey, M.D., Louis I. Dublin, Ph.D., Homer N.

Calver, John L. Rice, M.D., Mayor LaGuardia, Frederick Osborn, Livingston Farrand, M.D., and George Baehr, M.D.

DR. ROBERT H. RILEY HONORED FOR
TWENTY-FIVE YEARS OF SERVICE

ON July 5th the employees of the Maryland State Department of Health gave a testimonial banquet to Dr. Robert H. Riley, in honor of the 25 years since he joined the Department. The *Baltimore Sun* editorially points out that under Dr. Riley's leadership Maryland became the first of the 48 States to place its entire rural population under the protection of full-time local health officers. Credit is also given to Dr. Riley for the development of a statewide network of branch public health laboratories.

TULSA SEEKS COMPETENT SUPERIN-
TENDENT OF HEALTH

THE City of Tulsa, Okla., population 141,000 plus 35,000 in surrounding metropolitan areas, has recently recast its public health program through an ordinance which provides for a non-partisan health board to have jurisdiction over all public health work. It is expected that this set-up eventually will become a coöperative program between the city and county, and the health work in the public schools may also be included.

The new program is based on a public health survey recently completed under the auspices of certain of the city officials. The program is said to have the full approval and complete coöperation of the Tulsa County Medical Society which shared in promoting its consideration. It is announced that the immediate problem of the Board of Health is to secure a competently trained, experienced full-time superintendent of health and that the Board will receive applications from qualified persons for this position.

DR. STAMPAR AT UNIVERSITY OF
CALIFORNIA

DR. Andriya Stampar, Professor of Social Medicine, State University, Zagreb, Yugoslavia, has been named to the newly created post of Rosenberg Professor in the Public Social Sciences at the University of California, Berkeley. Dr. Stampar will be the first to hold the position, which was created by a gift from the Rosenberg Foundation of San Francisco. A graduate of the University of Vienna, Dr. Stampar formerly served as Director of Health of Yugoslavia. He was adviser on health matters to the National Government of the Chinese Republic from 1933 to 1936, when he became expert on health matters to the health section of the League of Nations. He was a visiting lecturer under the Rockefeller Foundation in the United States in 1938.

While on the Berkeley campus he will give two courses, one for graduate students and one for upper division students. He will also deliver a series of public lectures on the campus, and, by special conditions of the Foundation grant, will be enabled to visit other parts of the state for lectures and consultations, according to the *Journal of the American Medical Association* of July 1, 1939.

MARYLAND LAW REGARDING HEALTH
COMMISSIONERS

EFFECTIVE June 1, 1939, a new law in Maryland provides for the appointment of the Director of the State Department of Health by the State Board of Health rather than by the Governor as in previous years.

The new law makes the Commissioner of Health of the City of Baltimore ex-officio one of the nine members of the State Board of Health, and Dr. Robert H. Riley is designated as the Director of Health, to continue in this capacity indefinitely, subject

only to competent performance. It is provided that the Director of Health must be an experienced physician, skilled in public health and hygiene, and he may be removed by the Board of Health only for incompetency or misconduct in the same manner as civil officers receiving appointment from the Executive for a term of years.

CANADIAN PUBLIC HEALTH ASSOCIATION

OFFICERS of the Canadian Public Health Association have been elected for 1940 as follows:

Honorary President: The Hon. J. M. Uhrich, M.D., Regina (Minister of Health, Province of Saskatchewan)

President: Dr. R. O. Davison, Regina (Deputy Minister of Public Health, Saskatchewan)

Vice-Presidents: Dr. Grant Fleming, Montreal (Dean, Faculty of Medicine, McGill University); Dr. Jean Gregoire, Quebec (Deputy Minister, Ministry of Health of Quebec); Dr. J. J. McCann, Renfrew, Ontario (Medical Officer of Health, Renfrew); Miss Elizabeth L. Smellie, C.B.E., Ottawa (Chief Superintendent, Victorian Order of Nurses for Canada)

Honorary Secretary, Dr. J. T. Phair, Toronto (Chief Medical Officer of Health, Province of Ontario)

Associate Secretary, Dr. A. H. Sellers, Toronto (Medical Statistician, Department of Health of Ontario)

Honorary Treasurer, Dr. A. L. McKay, Toronto (Department of Health of Ontario)

Chairman of the Editorial Board, Dr. R. D. Defries, Toronto (Associate Director, School of Hygiene and Connaught Laboratories, University of Toronto)

BLOOD STUDY INSTITUTE

THE University of Wisconsin Medical School, Madison, has announced an Institute for the Consideration of the Blood and Blood-forming Organs, September 4-6. In addition to the consideration of many aspects of anemia, a section will be devoted to consideration of the anemias of nutritional deficiency, under the direction of Dr. George R. Minot, of the Harvard Medical School and the Thorndike Memorial Laboratory, Boston.

NEW YORK CITY INDICTMENT DROPPED AGAINST COMMISSIONERS OF HEALTH AND SANITATION

ON April 4 a Grand Jury of the Borough of Queens returned indictments against several individuals and companies including John L. Rice, M.D., Commissioner of Health, and William F. Carey, Commissioner of Sanitation, charging that land fill dumps of waste and garbage at various points were a nuisance and that they endangered public health and safety. A change of venue to Bronx County was granted on May 16, and on June 19 the New York State Supreme Court dismissed the indictments under an agreement to let an impartial commission arbitrate the matter. Under the terms of this agreement, Dr. Thomas Parran will appoint a board of five, consisting of four physicians outstanding in health work and an experienced sanitary engineer, to make an investigation and examination of the land fills maintained by the Department of Sanitation.

This board was asked by the Court not only to decide whether the land fills were a menace to public health and safety but to suggest possible improvements, even if they were not found to be a menace. Subsequently, Dr. Thomas Parran, according to the press, announced the appointment of the following: Eugene L. Bishop, M.D., C.P.H., Milton J. Rosenau, M.D., Huntington Williams, M.D., Dr.P.H., Kenneth F. Maxcy, M.D., Dr.P.H., and Ralph E. Tarbett, C.E.

JOHNS HOPKINS UNIVERSITY DEPARTMENT OF PREVENTIVE MEDICINE

THE Dean of the Johns Hopkins Medical School, Baltimore, has announced that the Rockefeller Foundation has appropriated funds covering a ten year plan to establish a department of preventive medicine in the amount of \$350,000.

INTERNATIONAL CONGRESS FOR MICROBIOLOGY

THE Third International Congress for Microbiology will be held in New York at the Waldorf-Astoria Hotel, September 2-9, 1939. More than six hundred papers on a variety of subjects will be presented, including papers on bacterial variation and taxonomy, microbiological chemistry and physiology, viruses and viral diseases, rickettsias and rickettsial diseases, fungi and fungous diseases (including bacterial diseases of plants), protozoölogy and parasitology, medical and veterinary bacteriology (including chemo- and sero-therapy), industrial and agricultural microbiology, and immunology.

Anyone interested in these subjects may attend the meetings. A registration fee of \$5.00 will be charged. Those wishing to attend would do well to communicate with the treasurer, Dr. Kenneth Goodner, Rockefeller Institute, York Avenue and 66th Street, New York, N. Y.

PUBLIC HEALTH WEEK OBSERVATION IN NEW JERSEY

THE Bergen County [N. J.] Medical Society sponsored a Public Health Week, beginning May 14, in coöperation with public health groups. Exhibits were shown at various hospitals.

A meeting was held under the auspices of the woman's auxiliary to the county society in Hackensack on May 19, with Haven Emerson, M.D., of New York, as the speaker on "Organized Care of the Sick and Public Health in Relation to 'Socialized Medicine.'" The motion picture "The Birth of a Baby" was shown in Hackensack on May 20 to invited groups. The week was concluded, on May 21, with the dedication of an "orthopedic pool" at the Bergen County Hospital, presented by the American Legion.

NEW HEALTH OFFICER IN MICHIGAN

THE appointment of A. J. Moyer, M.D., of Charlotte, Mich., as State Health Officer, succeeding Don W. Gudakunst, M.D., Dr.P.H., effective August 1, has been announced by the Governor.

ARIZONA PUBLIC HEALTH ASSOCIATION OFFICIALS

AT its recent Annual Meeting the Arizona Public Health Association elected the following officers for 1939-1940:

President—W. W. Peter, M.D., Window Rock

President-elect—H. D. Ketcherside, M.D., Phoenix

1st Vice-President—O. W. Fowler, Phoenix

2nd Vice-President—Fred J. Baker, Flagstaff

Secretary-Treasurer—Marion E. Stroud, Phoenix

GEORGIA PUBLIC HEALTH ASSOCIATION OFFICIALS

AT its recent Annual Meeting, the Georgia Public Health Association elected the following officers for the year 1939:

President—William H. Weir, Atlanta

Vice-President—Elizabeth Fulcher, Marietta

Secretary-Treasurer—Gordon T. Crozier, M.D., Valdosta

MICHIGAN STATE COUNCIL OF HEALTH

NEW members of the Michigan State Council of Health, recently appointed by Governor Dickinson and confirmed by the Senate for terms of six years, include:

President: Henry F. Vaughan, Dr.P.H., Detroit

Secretary: John Lavan, M.D., Grand Rapids

A. D. Aldrich, M.D., Houghton

Carleton Dean, M.D., Charlevoix

Roy C. Perkins, M.D., Bay City

This Council serves in an advisory capacity to the State Health Commissioner.

OHIO FEDERATION OF PUBLIC HEALTH OFFICIALS

THE Ohio Federation of Public Health Officials held its Annual Convention in Columbus on May 19, 1939, at which time the following officers were elected for 1939:

President—Dr. H. H. Pansing, Dayton, O.
Vice-President—Dr. E. H. Schoenling, Cincinnati, O.

Secretary-Treasurer—Dr. W. D. Bishop, Greenville, O.

Delegate to A.P.H.A.—Dr. G. D. Lummis, Middletown, O.

Alternate—Leo F. Ey, Columbus, O.

PERSONALS

Central States

GEORGE E. ADAMS, Deputy Registrar of Vital Statistics for the City of Milwaukee, Wis., for 29 years, and a Health Department employee for 53 years, has retired.

DR. JOHN K. ATLAND, of Allegan, Mich., has been appointed Director of the newly created health unit in Traverse County.

GREGOIRE F. AMYOT, M.D., D.P.H.,* who has been Administrative Associate of State Health Studies conducted by the Committee on Administrative Practice of the American Public Health Association, has accepted an appointment during the fall and winter quarters of the coming academic year in the Department of Preventive Medicine and Public Health at the University of Minnesota, Minneapolis. Dr. Amyot will have charge of the formal instruction in public health administration.

ALBERT C. BAXTER, M.D.,† Acting Director of the Illinois State Department of Health since 1937, has been appointed head of the Department.

DR. WILLARD G. BEATTIE, of Farmdale, Mich., resigned as City Health Officer, effective May 15, to devote his time to private practice.

PHILIP E. M. BOURLAND, M.D., M.S.P.H.,† of Iron Mountain, Mich., has resigned as Director of the Dickinson County health unit.

RUTH E. BOYNTON, M.D.,† Associate Professor of Preventive Medicine and Public Health, University of Minnesota Medical School, Minneapolis, Minn., has been appointed to the State Board of Health.

HERMAN N. BUNDESEN, M.D.,* who has been on a leave of absence since November, 1938, has returned to his activities as Health Commissioner and President of the Board of Health of Chicago.

GEORGE A. DUNDON, B.J.,* Director of Statistics and Health Education, of the Department of Health, has been appointed Deputy Registrar of Vital Statistics for the City of Milwaukee, Wis., succeeding GEORGE E. ADAMS, retired.

BURT A. DYAR, M.D., of Pierre, S. D., has been appointed full-time secretary of the State Interallied Professional Council, which represents the medical, dental, nursing, hospital, and pharmaceutical associations.

DR. DARREL L. EVANS, of Manhattan, Kans., recently resigned as Health Officer of Riley County.

DR. EDWIN H. FEDERMAN, of Montello, Wis., has been appointed Health Officer of Eau Claire County.

DR. PERCY A. PETITT, of Paola, Kans., has been appointed Health Officer of Miami County.

EDWIN H. PLACE, M.D.,† of Midland, Mich., who has been attending the University of Michigan School of Public Health on a leave of absence, has resigned as Health Officer of Midland County. Dr. Place has accepted a fellowship for study in

* Fellow A.P.H.A.

† Member A.P.H.A.

public health with the Kellogg Foundation of Battle Creek.

HARVEY J. SKARSHAUG, M.D.,† of Fargo, N. D., has resigned as City Health Officer.

DR. ALFRED R. SORENSON, of Minot, N. D., has been appointed City Health Officer, succeeding DR. JOHN L. DEVINE.

Eastern States

ALFRED J. ASGIS, D.D.S.,† of New York, N. Y., had the degree of Ph.D. conferred upon him at the June commencement at New York University.

MERLE R. FRENCH, M.D.,* who has been for several years Commissioner of Health for Cortland County Department of Health, Cortland, N. Y., has resigned, effective September 1, to become Health Director of Van Buren County, Paw Paw, Mich.—one of the counties participating with the W. K. Kellogg Foundation in a special health program.

PROFESSOR IRA V. HISCOCK,* of the Department of Public Health, Yale University, New Haven, Conn., was awarded an honorary Doctor of Science degree at the June commencement of Wesleyan University, Middletown, Conn.

DR. ALFRED NEWTON RICHARDS, Professor of Pharmacology at the University of Pennsylvania, Philadelphia, Pa., has been elected Vice-President of the University in charge of medical affairs and in this capacity will have supervision of the teaching in public health to graduate and undergraduate students newly organized under A. Parker Hitchens, M.D.,* Pepper Professor of Preventive Medicine and Public Health.

HANS ZINSSER, M.D.,* was awarded the honorary degree of Doctor of Science by both Yale University and

Harvard University at the June Commencement exercises.

Southern States

DR. LEE SCOTT BARKSDALE, of Richmond, Va., has been appointed Health Officer of Hopewell.

DR. CHARLES E. CATCHINGS, of Woodville, Miss., was recently named Health Officer of Wilkinson County, to fill the unexpired term of DR. EDWIN M. BUTLER, of Centerville, who has been appointed Health Officer of Union County.

DR. JOHN W. DORMAN, of Holly Springs, Miss., was recently placed in charge of the Marshall County Health Department, succeeding GUY R. POST, M.D.,† who went to Clarksdale.

Developments in the New York State Tuberculosis Program*

ROBERT E. PLUNKETT, M.D.

*General Superintendent of Tuberculosis Hospitals, Division of
Tuberculosis, State Department of Health, Albany, N. Y.*

THE behavior and control of tuberculosis, whether in the individual suffering from the disease or as a community problem, depend upon the proper control and disposal of bacilli-laden sputum. Control the sputum and spread is prevented; neglect this measure and cases multiply.

Although the tubercle bacillus is the specific cause of tuberculosis, it must be recognized that other factors contribute to both the epidemiology and pathogenesis of the disease. These contributing factors may be grouped under two headings—the constitutional and the environmental. Of these, the environmental factors are legion and appear to play a more common part in disease development than the constitutional. Recognizing the variables which may influence the disease in certain racial, industrial, and social groups, it can be stated that contact with a sputum positive case, with its oppor-

tunity for infection and reinfection by frequent and massive doses of tubercle bacilli, appears to be the most important single factor.

Keeping in mind the significance of bacilli-laden sputum, the following procedures are essential in the administration of control measures: The reporting and registration of cases of tuberculosis, active and progressive case finding, the segregation and treatment of patients suffering from the disease, domiciliary supervision of families in which tuberculosis is or has been a problem, rehabilitation of cases, the follow-up of all cases and contacts, and financial assistance to needy families in a manner free from the stigma of pauperism. Equally important is the periodic appraisal and evaluation of procedures and services, both from the viewpoint of administrative economy and the more effective extension of our knowledge of the epidemiology and pathogenesis of the disease.

From its beginning in 1913 when the Tuberculosis Division of the New York State Department of Health was estab-

* Read before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

lished, the growth and development of the program for the control of tuberculosis has been constant and progressive. At that time, reporting of cases and provision of sufficient hospital beds were the two factors of major importance, and the promotion of these were the two major activities of the division.

Since 1917, counties having more than 35,000 population have been required by law to maintain a tuberculosis hospital. As a result, 31 counties and 2 cities constructed sanatoria, and at the present time the beds in these hospitals, plus the beds in the 4 state tuberculosis hospitals, provide a ratio of 2.4 public beds for every death from tuberculosis. Including all other beds available in public and private institutions this ratio is 3.8.

The importance of having a roster of all known living cases of tuberculosis is too obvious to require discussion. In order that better local control and supervision of that problem could be effected, each of 20 state health districts maintains its own district roster, properly indexed and filed, whereby the size of the problem can be gauged and individual supervision provided. All reports are forwarded to the central office.

Coincidental with these developments came the gradual change from specialized tuberculosis field nursing service to a generalized nursing program in which tuberculosis assumed its proper relationship. Supervision and guidance of this nursing service, which is on a local basis, are provided through supervising nurses of the district health offices, the consultation nurses of the state tuberculosis hospitals, and the assistant directors of the Public Health Nursing Division of the central office.

As these state-wide activities were being developed and enlarged, the division undertook another activity of

major importance—case finding. This led to the establishment of an itinerant diagnostic chest clinic service on a strictly consultation basis in coöperation with the practising physicians. This provided a service to the rural areas where it was lacking. It required some time at the beginning to gain the good will and coöperation of the private physician, but soon this service became very popular with both physicians and patients.

As a result of the recommendations of the Governor's Health Commission appointed in 1930, 3 new state tuberculosis hospitals were constructed to serve 3 groups of small counties, and a new 100 bed infirmary building is nearing completion at the State Hospital for Incipient Tuberculosis at Ray Brook. The Ray Brook Hospital, established in 1904, was for the admission of patients with incipient or minimal tuberculosis from the entire state, but this new addition at the hospital will also serve as a district hospital for that area the same as the 3 new hospitals. The 4 areas serve 31 counties.

With the establishment of these new hospitals, the field clinics hitherto conducted by the staff of the central office were discontinued, that function, intensified and extended, being taken over by the hospitals.

In translating the above into administrative practice in New York State, the responsibility for the program is placed in the Division of Tuberculosis. There are 57 counties in upstate New York with an estimated total population of 6,080,444. These counties vary in population from 3,929 to 813,786. The death rate from tuberculosis for upstate New York has dropped from 161.5 per 100,000 in 1900 to 44.7 in 1938. Reference is made to Exhibit A.

The purposes of the division may be considered as threefold: (1) direct service to the people examined and studied, their families, and communi-

DEATH RATES, PER 100,000 POPULATION, FROM TUBERCULOSIS (ALL FORMS)
NEW YORK STATE EXCLUSIVE OF NEW YORK CITY
1900 - 1937

Exhibit A

ties; (2) research through the acquisition of data, its classification and interpretation; and (3) education of the public and the medical profession. Knowledge of the scope and extent of the disease problem in a community is as essential to the health officer as the extent and character of a lesion in an individual patient is to a clinician. Such knowledge may be acquired from detailed morbidity and mortality data.

By complete checking of detailed information on death certificates regarding residence, etc., and prompt and complete reporting of existing cases, the health officer is able actually to take stock and be guided wisely in his administrative program. To provide such opportunities, the reporting of tuberculosis cases is constantly being promoted by both the district offices and the division staff. Consequently, the tuberculosis report cards are routed, except for our largest cities and county health district areas, through the office of the district state health officer. Each district officer maintains a case register

for all reported cases residing in his district. The name, address, sex, age, clinical stage, and sputum status are all catalogued by the use of colored flags in a visible index file for ready reference in follow-up, public health nursing supervision, and all forms of community assistance toward control. Current data relating to the patient are secured from clinics, tuberculosis hospitals, and private physicians, from which each district officer is able to make periodic appraisals of the tuberculosis problem either in his entire district or in any of the counties within the district.

Time does not permit a detailed review of the many other advantages of having this information readily and constantly available. Obviously, the district officer is thereby enabled to direct more intelligently the field activities in tuberculosis control, to use the data in promoting advances in case-finding methods, to secure additional clinic sessions, and to employ the necessary number of public health nurses. Such data are most essential in direct-

ing the local public health nursing service along the most productive channels. Exhibit B shows the state health district areas.

The case finding activities in upstate New York are closely integrated in practically all localities with the 31 local tuberculosis hospitals and sanatoria. All the county tuberculosis hospitals

conduct a case finding service as an activity of their out-patient departments. Except in one or two counties in which the total area of the county is very small, each of the hospitals conducts itinerant clinics in various sections of the respective counties. Emphasis is placed upon the examination of contacts and patients who may be

referred by their family physicians because of symptoms referable to the chest. There are altogether approximately 120 semi-permanent or permanent clinics or dispensaries, in addition to a similar service which is available for the people periodically through the above itinerant service. The total number of examinations conducted in these local clinics approximated 55,000 in 1937. The total number of annual clinic examinations throughout upstate New York is between 90,000 and 100,000. Exhibit C shows the distribution of diagnostic clinic service.

The total number of special beds for tuberculosis in upstate New York is 10,326 as compared with 2,716 deaths. Of these beds, 5,537 are in state and local tuberculosis hospitals and the balance in private hospitals or other state institutions. The ratio of total beds to deaths is 3.8 and the ratio of special public beds to resident deaths is 2.4. Exhibit D shows the geographic distribution of public tuberculosis hospitals.

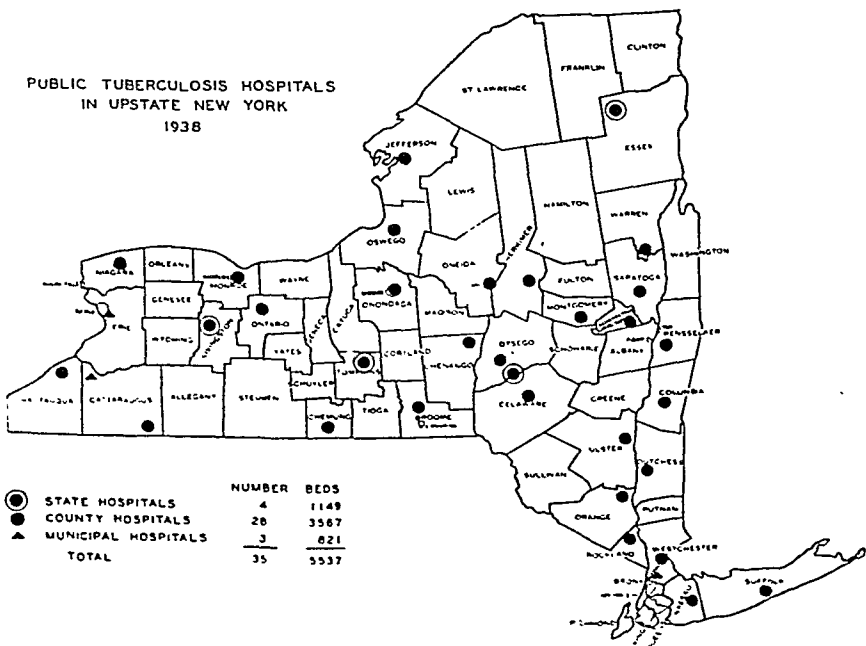

In 1930, the State Health Commission, following an intimate study of the

tuberculosis control problem in New York State, recommended that the state construct 3 new tuberculosis hospitals and add an infirmary to Ray Brook, the one state tuberculosis hospital then existing, in order to provide hospital and other control facilities not then available in 25 counties.

Each of these hospitals has been constructed in the population center of the area served. Each acts as the hub of the wheel of tuberculosis control. A continuity of medical service from case finding through treatment and follow-up of both patient and family prevails in each hospital. Tuberculosis is approached on a family and community basis, while the patient is treated as an individual.

The fact that practically 100 per cent of the general practitioners participate and coöperate by having their patients examined and studied by the hospital staffs, has contributed more to the success of these hospital programs than any other single factor.

Each state hospital conducts an active consultation type of out-patient service within the hospital and through

clinics held throughout each county in the area. Patients are admitted to the clinics by a request card signed either by their family physician or the local health officer. All patients are referred back to their physicians for a report of the examination, which is completed in detail and mailed to the referring physician. Copies of these reports are sent to the district state health officer and the local public health nurse for assistance in follow-up work.

In this clinic service, emphasis is placed upon the history of contact with a known case of tuberculosis. Patients who have experienced such contact, as well as patients who are referred by their family physicians because of suspicious symptoms or physical signs, comprise the patient attendance.

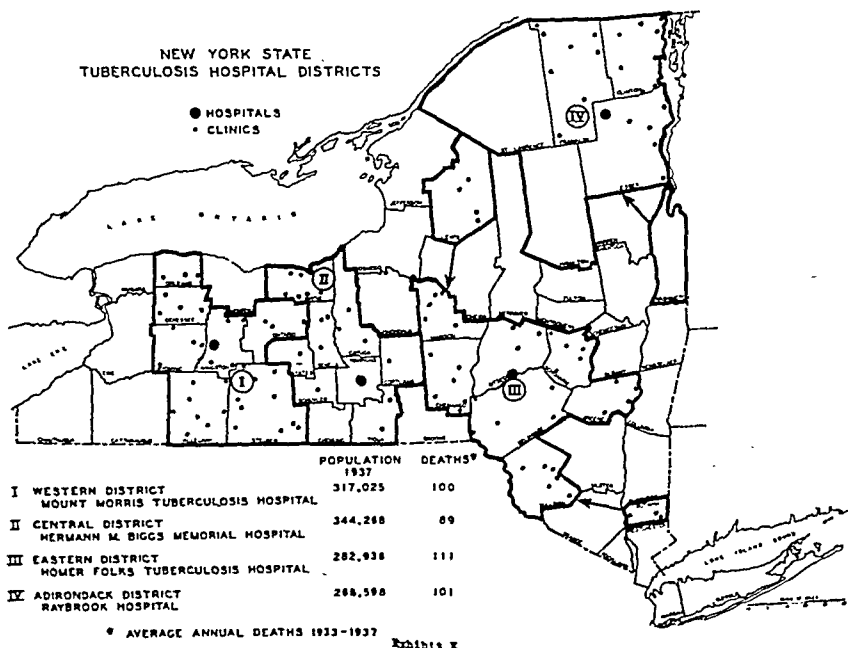

These hospitals have been in operation for approximately 3 years, and during the past 2 full years of clinic administration a total of 21,804 individuals, comprising 1.8 per cent of the total hospital area's population have been examined. The yield in newly discovered cases of tuberculosis among

these patients was 3.1 per cent. About 50 per cent of the patients were examined because of history of contact. Of real significance is the fact that of those patients found with tuberculosis because of the history of contact, 67 per cent were in the minimal stage of their disease, in contrast to 40 per cent of those who presented themselves to the clinic because of symptoms. Exhibit E shows the outline of these tuberculosis hospital areas.

Patients are admitted to the hospitals for special study or treatment either by applying through their family physician, health officer, or directly to the superintendent of the hospital.

Each hospital maintains a more detailed case register for its district than that of the district state health officer. All families in which tuberculosis may be a problem are indexed in detail as to their status regarding infection, chest X-ray, contact with sputum positive case, clinical status, and other social and epidemiological data.

Complete medical and surgical facilities are available in each hospital. All

nurses are registered, and all physicians are employed full time. One full-time thoracic surgeon has been performing the major operations during alternate visits to the 3 new hospitals, although each hospital has a resident surgeon. The surgical program in Ray Brook will be started on July 1, with the employment of an additional thoracic surgeon.

The care and treatment of orthopedic patients are directed by the physicians in our Division of Orthopedics by periodic visits to each hospital.

Research and teaching characterize all phases of the program in each hospital. For many years, medical students have had the benefit of residence teaching at Ray Brook, and this service, together with teaching programs through affiliation with schools of nursing, is continually carried on in the 3 new hospitals.

Although the laboratory in each hospital conducts all routine examinations, each one is carrying on studies in different fields of research—in one, bacteriology; in a second, physiology of respiration; in a third, special studies relating to the tissue reaction to the tubercle bacillus, and in the fourth, pathology. In this manner, duplication of work is avoided and the special resources of any one laboratory are available to all the hospitals.

Among the special studies relative to the epidemiology and pathogenesis of tuberculosis which are being carried on are:

1. X-raying of workers in heavy industries and dusty trades (8,500 already completed)
2. Periodic tuberculin testing and X-raying of students in 9 state teachers' colleges (6,000 examined to date)
3. X-raying of patients and employees in mental hygiene hospitals, where the tuberculosis death rate approaches 812 per 100,000
4. Continuing and periodic examination and reexamination of 2,300 inmates of a school for feeble-minded
5. Similar tuberculin testing and X-ray

study of 500 inmates of a state institution for delinquent girls

6. X-raying of 5,000 adult admissions to general hospitals

7. X-raying of 1,500 employees in a food production plant

8. Continuing detailed studies of the economic factors in tuberculous families, in relation to the individual, the family, and the community.

In addition to the above, other special studies—either as a part of routine administrative procedures or as special projects—are being conducted regarding such detailed aspects of the control problem as: Circumstances influencing the reporting of tuberculosis cases by private physicians; the longevity of tuberculosis patients following the onset of symptoms or the diagnosis; the relative value of the various methods of treatment, including collapse therapy; the appraisal of various routine administrative methods used in clinics, dispensaries, and tuberculosis hospitals; the determination of significant and helpful factors favoring the rehabilitation of patients and their reestablishment as self-sustaining persons in the community.

SUMMARY

To spread tuberculosis a human being must have an open lesion. The epidemiology and the study of the control of tuberculosis present a more complex problem than almost any other of the communicable diseases for which the cause is known. The transmission of infection occurs most frequently among persons in intimate contact with the patient who has the disease. Of all persons who become infected with the tubercle bacillus, only a small percentage develop the reinfection type of tuberculosis. Pulmonary tuberculosis is a disease primarily of adults. Environmental factors seem to have a more common influence on the development of disease than do the constitutional factors. The most common en-

vironmental denominator found in the tuberculosis problem is the almighty dollar. A vicious circle is formed by poverty and tuberculosis and tuberculosis and poverty. Before many specific factors can be individually evaluated, more information must be obtained. If, however, our present knowledge could be applied to our present and future medical and public health practices, the mass behavior of tuberculosis would be changed. The

tremendous amount of needless suffering, the unnecessary deaths, and the enormous economic losses resulting from the disease can be appreciably reduced. They should be.

From the foregoing, it is evident that the tuberculosis control program of the New York State Department of Health embraces all of the accepted procedures. Facilities for administrative control are universally available throughout every section of the state.

Athletics for Girls

THE American Public Health Association was represented at the 16th annual meeting of the Women's Division of the National Amateur Athletic Federation in San Francisco in May by Pauline Brooks Williamson, Chief of the School Health Bureau of the Metropolitan Life Insurance Company.

The National Amateur Athletic Federation is an affiliated organization of the American Association for Health, Physical Education and Recreation.

In her report to the Executive Board, Miss Williamson points out that the National Amateur Athletic Federation has throughout its history encouraged

the democratic principle of a sport or game for every girl and not for just the few who excel. The Federation believes that every girl should be given an opportunity to participate in sports according to her needs as revealed through a thorough medical examination and by her interests and ability. Competition that stresses enjoyment of sport and the development of good sportsmanship is emphasized rather than those types that aim at the making and breaking of records, the winning of championships for the enjoyment of spectators, or the athletic reputation or commercial advantage of institutions and organizations.

Occurrence, Pathological Aspects, and Treatment of Fluoride Waters*

M. STARR NICHOLS, PH.D., F.A.P.H.A.

*Chemist, Wisconsin State Laboratory of Hygiene, and Associate
Professor of Sanitary Chemistry, University of Wisconsin,
Madison, Wis.*

ADEQUATE proof that minute amounts of fluorine as fluorides in drinking water produce an imperfect enamel structure in the teeth during the formative period of the enamel has created a serious problem in water supply, not only throughout the nation, but throughout the world in general. Furthermore, the action of fluorine may not be confined to the teeth, but may have pathological effects upon other parts of the body structure. On the other hand, no proof has been brought forward to show that it is altogether a useless or harmful element rather than an element active and needed in minute

quantities such as is the element of copper. That body well-being can be maintained on extremely minute quantities of fluorine as it can be on minute quantities of the essential element iodine is found in the fact that many waters contain only very small quantities of fluorine yet cause no outstanding apparent defects in body metabolism. Few waters can be found that do not show as much as 50 micrograms of fluorine per liter, which is the approximate amount of iodine required daily to prevent simple goiter.

The problem, without doubt, is to provide drinking water which contains

a minimum amount of fluoride, since mottled enamel, which is produced at levels of at least 1 p.p.m. and above, is certainly evidence of definite ab-

FIGURE I—Distribution of mottled enamel in the United States up to 1938

normal physiology, as proved by Dean, Dixon, and Cohen.¹

In Table I, taken from report by Dean and Elvove,²⁷ are shown data for the incidence of mottled enamel in children correlated with the fluoride content of waters from widely separated cities in the United States. Such a correlation as shown is rather conclusive evidence that fluorides alone are responsible for the mottled enamel since the mineral content of these waters and the diets of the children examined from so many divergent localities are bound to be different.

Water supplies low in fluorides must be obtained either by the selection of a suitable water free from excessive amounts of fluorides or treatment of unsuitable supplies to reduce the fluoride to the "safe" level. Waters known to contain excessive amounts of fluorides are widespread throughout the United States and evidence is fast accumulating that such waters are found widely distributed throughout the

world. In Figure I is shown the distribution of areas known to have mottled enamel and in most cases the waters are known to contain excessive fluorides. The question naturally arises: From what stratum or source do these fluoride waters arise? McKay in 1918² pointed out that the inhabitants of many endemic areas used artesian water. He also pointed out that the artesian waters of the great plains were obtained from the Dakota sandstone and that the original source of this water was the east side of the Rocky Mountain watershed. In general fluoride waters are derived from wells but not necessarily from sandstone. In Ohio³ many of the fluoride waters appear to rise in the limestone. In the Colorado Springs area the surface water from Pike's Peak watershed seems to be the source of the fluoride, and such water entering the western outcrops of the Dakota sandstone and underlying sedimentary formations at the Rocky Mountains may furnish the

FIGURE II—Areas of igneous rocks (dark) with possible relationship to entrance of percolating fluoride waters

fluorides in many places in the western plains, including the large endemic area of northwestern Texas.

In Figure II a relief map of the United States shows the general geologic conditions. Note the Piedmont areas adjacent to the igneous protrusions into which drainage water from igneous formation percolates. The presence of mottled enamel in areas adjacent to Mt. Vesuvius in Italy appears to have been associated with waters which had their origin on the laval surfaces of that volcano. In gases from volcanoes and fumaroles fluorine compounds⁵ have been found. Geologic data bearing on the probability of procuring fluoride-free ground water would provide assurance to the municipality that a given well development would probably be successful. That such data ever will permit of definite interpretation is by no means certain since fluoride compounds are very widely distributed in many types of rock formation.

Since fluorine is a very reactive ele-

ment it is seldom found free in nature. Calcium fluoride, fluorite, CaF_2 and cryolite the double salt of sodium and aluminum with fluorine are two of the naturally occurring minerals which contain large quantities of fluorine. The origin of all fluorine bearing minerals is of course the igneous rocks underlying all sedimentary formations. Recorded analyses of several thousand igneous rock structures as compiled by Washington⁶ and which give results for fluorine in about two hundred analyses, show this element to be present in about 85 per cent of the igneous rocks tested. The amount of fluorine contained in these rocks varied from 0.01 to 3.36 per cent, with an over-all average of 0.23 per cent.

In Table II are given results showing that there were only 40 rocks of the 172 that contained more than the average amount of fluorine and that of these there were only 8 which contained the element in amounts above 1.0 per cent. Fluorine was found in not only many different kinds of rocks but it

TABLE II

Showing Distribution of Fluorine Content as Found by Analyses of 172 Igneous Rocks from Different Parts of the World

<i>Content of F. Per cent Incl.</i>	<i>Number of Different Rock Specimens Showing F.</i>	<i>Per cent of Total Numbers of Rocks Showing F.</i>
0.01 to 0.05	57	33.2
0.06 to 0.09	35	20.3
0.1 to 0.23	40	23.3
0.24 to 0.50	19	11.0

Above 3.36	None	
Total	172	100.0

was also rather evenly distributed among the various classes of igneous rocks. The occurrence of fluorides in sedimentary formations seems to be still more erratic than that in primitive rocks.

A study of the fluorspar deposits of southeastern Illinois and northwestern Kentucky shows that these were laid

down along fault and fissure lines as shown in Figure III, which is taken from work by Bastin.⁷ Note that the fluoride is laid down vertically and horizontally as a vein mineral in these deposits. According to Fohs⁸ these deposits of fluorspar were depositions resulting from thermal waters laden with fluorides or fluorsilicates arising in the igneous rock formations, ascending and spreading laterally through these fissures which developed along the faults in the sedimentary formations. He states:

These several deposits occur both filling open cavities and as replacement of adjacent rock . . . Likewise they occur in tabular deposits, filling vertical or inclined faults or fissures, as horizontal deposits along bedding planes, faults or replacing bedded strata and filling stock works: hence irregular in outline.

There is in these findings an indication that faults and fissures which extend upward from primary rock strata are important geologic signs of fluoride bearing waters. Near the location of the fluoride water area in northeastern

FIGURE III—Faults and fissures in sedimentary formations permitting thermal magmatic fluoride bearing waters to ascend and spread laterally (*Drawing from Bastin*)

Diagrammatic cross-section showing stratigraphic and structural relations in the vicinity of Rosiclare.

Wisconsin are known to exist faults, and their proximity suggests a possible cause for these few fluoride waters of that state. A similar condition exists in the fluoride area between Moline and Peoria, Ill. The derivation of fluor spar deposits suggests also that no particular limestone strata can be held responsible for fluoride waters but that any of the sedimentary formations could be interspersed with fluoride deposits. It appears, however, that replacement deposits as well as deposits filling cavities are more likely to occur in limestone formations since these are known to be subject to channel formations which are favorable to depositions as well as re-solution.

Sundstrom and McKee¹⁰ show by means of well packers that fluoride in amounts of about 2.0 p.p.m. is present in both limestone and sandstone water from a well drilled 916 feet to granite in Wisconsin's fluoride area.

Fluorapatite, $\text{Ca}_5(\text{PO}_4)_3\text{F}$, is another mineral which may be responsible for the presence of fluorides in natural waters, as it is a rather common constituent of all classes of rocks—igneous, metamorphic, and sedimentary, and forms the source of fluorine in the phosphate rock deposits of Florida, Tennessee, Virginia, Idaho, and Montana. The fluorine content of these materials varies from practically zero to 4 per cent, and the presence of this element in these products, which are used both for fertilizer, as a supplementary mineral in stock feeding, and as a source of phosphate in baking powders, has occasioned much experimentation on the physiological effect of fluorine on both animal and plant life.

PATHOLOGICAL ASPECTS OF FLUORIDES

De Eds¹¹ and McClure¹² have recently made excellent reviews of the subjects up to 1933. Of the vast amount of material available in this literature of nearly 150 articles, only a few out-

standing points can be given here. Fluorine as fluorsilicates, sodium fluoride, rock phosphate, and calcium fluoride show toxicity to the animal body in the order given and in comparatively small amounts. Leake in 1928¹³ showed 87.5 mg. of sodium fluoride per kg. when given intravenously to be fatal for rabbits in about 40 minutes. Many cases of fluoride poisoning of humans are to be found in the literature and as little as 4 gm. has proved fatal when taken by stomach.

The chronic poisoning by fluorides is an entirely different matter. Here the changes in body tissue are gradual and adjustments to the fluoride intoxication are made so that pathological evidence of toxicity is difficult to gather. Interpretation of animal toxicity experimentation in terms of human reaction is frequently difficult. It is a well known fact that the dose of certain drugs for dogs is 15 times as much as for man on an equivalent weight basis. Differences in life span and age at chemical maturity as well as species tolerances of adverse environment need be given their proper value when transposition of experimental results are made. Thus, Smith, Lantz, and Smith¹⁴ noted in their preliminary experiments on St. David water (F. from 4.2 to 7.1 p.p.m.) that "No destructive effect of the St. David water on the teeth of the rats was noticed when the diet was adequate in all respects." However, when rats were given this same water concentrated by evaporation to 10 times the original mineral content (F. 42 to 71 p.p.m.) gross defects (mottled enamel) occurred in the teeth within 1 month's time. While on the other hand, children using the unconcentrated St. David water developed mottled enamel practically 100 per cent. Such a result is explained on the basis of the rapidity of growth of the tooth structure of the rat as compared to humans.

Evidence has also been obtained that

the fluoride in some tissue may be present as an immobilization phenomenon since analyses have shown it to be present in all tissues. In muscle it is found present from 0.4 to 4.6 p.p.m.; from 1,180 to 1,800 p.p.m. in dental enamel, with a value of 700 p.p.m. for bone calculated to a dry basis. Normal results for fluorine in tissue is difficult to ascertain since all foodstuffs have been found to contain fluorine in varying amounts depending upon the locality of production. Analyses show an average of over 5 p.p.m. for fluoride in 32 edible food substances and 26.5 p.p.m. for 63 plant products with more fluoride in leaves than in stems and in skin of fruit than in pulp.¹²

Phillips, Hart, and Bohstedt¹⁵ found that an intake of 2 to 3 mg. per kg. of body weight per day (1.5 gm. of fluoride per cow) was the upper limit of tolerance for dairy cows. Even at this level toxic changes are manifest in the teeth and bones as seen from photographs by these authors. The fluorine content of the bones and teeth of these same dairy cows as reported by Chang, Phillips, Hart, and Bohstedt¹⁶ showed a great increase (10 to 20 times, depending upon the amount of fluoride fed), but liver, muscle, hair, and hoof remained practically unchanged. The thyroid glands, however, increased in fluorine content from 125 to 240 times the normal. Data by Evans and Phillips¹⁷ just published (1938) show fluoride content of the thyroid gland in hyperthyroidism to vary from 1.5 to 95 p.p.m. and all those containing more than 20 p.p.m. of this element were associated with a high basal metabolic rate, with one exception.

Sharpless and McCollum¹⁸ in answer to the question, "Is fluorine an indispensable element in the diet?" state in part that: "No difference could be noted between these and the control rats which were fed fluorine" (an amount equivalent to that taken on a

normal diet). "The rats on the low fluorine diet looked very well, were quite fat, and on the whole appeared normal." The teeth of these low fluorine rats were free of fluorine as far as could be determined, yet showed no gross deficiency or defect. From the description of the diet and methods of analyses used by these authors their low fluorine diet contained less than 1.0 p.p.m. F.

Ellis and Maynard¹⁹ used rats and fed sodium fluoride or bone meal equivalent in fluorine content to the extent of from 8 to 14 p.p.m. in a diet which contained 3.0 p.p.m. fluorine. They noted deposition of fluorine in bones and teeth with a lightening of the enamel in the teeth of those fed the diet plus added fluorine. No lightening occurred in those eating basal diet with 3.0 p.p.m. fluorine.

While no definite knowledge is yet available to show that fluorine is necessary for body function, there is much definite evidence that it is a toxic poison whose intake should be reduced to the lowest limit possible. Mention should be made of the recent finding of Dean,²⁰ however, that the dental caries attack rate is only about one-half as great in those children using fluoride waters and having mottled enamel as in children using water low in fluorides.

THE TREATMENT OF FLUORIDE WATERS

In those geographic areas in which excessive amounts of fluorides (1.0 p.p.m.) are present in the water supply the authority has three courses of action from which a choice need be made. (1) Remove the fluoride from the supply then in use. (2) Sink other wells in a different locality or stratum as advised by a competent geologist with the hope of procuring a safe and satisfactory supply low in fluorides. (3) Develop any available surface water supply which is found to be low in fluoride, adequate in quantity, and

capable of treatment by ordinary purification procedures so that a safe and suitable water may be obtained.

In many areas removal of fluoride seems to be the only method available since no surface supplies are obtainable and all ground waters show fluorides. Such a situation is reported to be present in the Texas "Panhandle" fluoride area which, according to Dean, Dixon, and Cohen,¹ constitutes the largest mottled-enamel area in the United States. Laboratory and semi-plant scale experimentation on the removal of fluorides followed rather slowly the discovery that fluorides in amounts above 1.0 p.p.m. was the cause of mottled enamel in teeth. Boruff²¹ published the first results on removal and came to the conclusion that treatment of water with alum (10 gr. per gal.) would reduce the artificially prepared sodium fluoride waters from 5.0 p.p.m. to less than 1.0 p.p.m. Activated alumina was found efficient in reducing the fluoride content from 5.0 p.p.m. down to from 0.5 to 2.3 p.p.m., depending upon the rate of filtration and quantity of water treated. He also reported a 60 per cent reduction by lime softening.

Swope and Hess²² carried out tests with Defluorite (activated alumina at that time) on Chetopa, Kans., water with a resulting reduction in fluoride content from 6.2 to less than 1.0 p.p.m., but such a process, to the author's knowledge, has not been employed by any municipality.

Scott, Kimberly, Van Horn, Ey, and Waring³ have found that fluorides may be removed by lime treatment at high pH values provided the water contains sufficient magnesium. Such treatment to be effective required removal of 91 p.p.m. magnesium in order to reduce the fluoride from 3.0 to 1.0 p.p.m., the safe level.

Elvove²³ has reported that fluorides can be removed from water with the

aid of tricalcium phosphate, magnesium oxide, or magnesium hydroxide, but states that the question of cost must be solved before it can be applied on a practical basis. MacIntire and Hammond²⁴ and Adler, Klein, and Lindsay²⁵ nearly simultaneously, have published experiments on fluoride removal by means of tricalcium phosphate with similar success but the latter authors appear to have pointed to a rather practical means of application of the treatment, that is, by using it as a filtering material. It is of interest to note that these authors prepared their chemical from commercial phosphoric acid of high purity and milk of lime of such proportions that a mixture of hydroxy apatite $3\text{Ca}_3\text{P}_2\text{O}_8\text{Ca}(\text{OH})_2$ and tricalcium phosphate $\text{Ca}_3\text{P}_2\text{O}_8\text{H}_2\text{O}$ results and constitutes the material now sold as Defluorite.

Regeneration of the bed with 1 per cent sodium hydroxide followed by washing, neutralization of residual alkali with dilute HCl and subsequent washing was practised but about 3.0 per cent of bed was lost per regeneration. They found this chemical to have more than twice the capacity of activated alumina used by Swope and Hess or 1.8 gm. of fluoride per kg. of filter bed. The initial cost of this removal material, the fact that 3 per cent of the bed was lost with each regeneration, besides the cost of chemicals for regeneration, have militated against any notable installations of the process.

Recently, Behrman and Gustafson²⁶ have improved the method of regeneration of Adler, Klein, and Lindsay²⁵ by the use of carbon dioxide in place of hydrochloric acid for the neutralization of residual alkali and have shown that the filter bed of chemical can be used indefinitely without any loss of filtering material. Moreover, it is possible to employ ordinary materials of construction and equipment when carbon dioxide is the neutralizing agent. The improve-

ment is covered by a patent application. Since only a very small fraction of a water supply is used for drinking and cooking, individual household units have been proposed which will treat a stated quantity of water of certain fluoride content, but if these are not controlled, a false sense of security will prevail at times when the capacity of the unit is spent.

Experimental work done in this laboratory with softening a water containing a total hardness of 240 p.p.m. with a fluoride content of 2.8 p.p.m. reduced the fluorides to 1.3 p.p.m. This water when treated with 10 grains of alum per gallon and filtered shows 50 per cent removal of fluorides. Neither ferric hydroxide nor hydrated manganese dioxide had any sorptive effect upon the fluorides.

Many phases of the fluoride problem are still unsolved and with the results of extended experimentation into the physiological effects of minute amounts of fluorides may come a demand upon both the chemist and geologist for fluorides lower than the present permissible limit of 1.0 p.p.m.

Morbidity and Mortality From Scarlet Fever in the Negro

PAUL B. CORNELLY, M.D., DR.P.H., F.A.P.H.A.

*Department of Bacteriology, Preventive Medicine and Public Health,
School of Medicine, Howard University, Washington, D. C.*

SCARLET fever is one of the communicable diseases which have been said to be less prevalent in the Negro than the white population. Ever since the census of 1879,¹ when for the first time comparative statistical data over any extensive area showed a ratio of 69.2 deaths from scarlet fever in the Negro to 1 in the white as compared with the ratio of 6.3 to 1 for deaths from all causes, various observers have commented on this difference. However, most of these investigators have based their statements on the recorded mortality rates for the southern states published annually by the Bureau of the Census. These differences for scarlet fever are well shown in Table I.²

No one has made a comparison of the scarlet fever experience of the Negro population in the South with that of the North, nor has this been contrasted with that of the white population in these two regions. In order to study this problem, questionnaires requesting the number of deaths and cases for certain age groups for each year from 1930 through 1934 were sent to the health officers of 13 southern states, 10 northern cities with large Negro populations, and 10 southern cities. Because the Bureau of the Census has not published estimates of population according to race since 1933,

rates were only computed for the 4 year period, 1930-1933. There are still several cities and states which do not compile their cases or deaths from scarlet fever according to age or race, and therefore in one or two instances, the interpretation of the data must necessarily be limited.

The data in Table II show the mortality rate from scarlet fever for both races in certain states and cities. For both races the death rates in the southern states and cities are lower than in the northern communities. In practically all instances, the colored mor-

TABLE I

1931	0.36	2.17
1932	0.29	1.60
1933	0.47	1.99

tality is also lower than the white, but this difference is greatest in the southern states, where the ratio of Negro to white deaths is 3.7 to 1; less marked in the southern cities, 2.4 to 1, and least in the northern cities where the ratio is 1.8 to 1.

* 1930-1932

The question whether this disparity in mortality may not be due to differences in the age distribution of both races may well be discussed at this

juncture. This factor does not seem to have any influence whatsoever. Pevaroff and Hindman³ investigated this matter and demonstrated that the disparity in mortality from scarlet fever in the two groups existed even after the rates were adjusted for differences in age distribution. Table III shows this well.

The distribution of deaths in the different age groups seems to be very similar for both races in the North and South. The significant fact, shown in Table IV, is the marked concentration of deaths in the age group 0-5 years in both races in most of the cities and states. In practically all of the communities from one-half to three-fourths of all the deaths among white and colored persons occurred in children under 5 years. Doull⁴ was among the first to call attention to this phenomenon in the white population in temperate and tropical climates. He explained the occurrence in the North on the basis of the degree of aggregation of population; while in the South he attributed it to one or all of 3 factors: a corresponding concentration of cases, an increase in the relative case fatality in the younger ages, or a development of an early and widespread immunity of the southern population.

When we turn our attention to the case fatality rates, certain differences are to be recorded. In Table V, it is observed that in 12 of the 16 communities, the case fatality rates are higher for the Negro than for the white. As with the mortality rates, the inequality in the case fatality rates for the two races is greater in the southern states and cities than in the northern cities. For the southern states the group fatality rates are 1.5 and 3.1 for white and Negroes respectively; for the southern cities, 1.1 and 1.9, and for the northern cities, 1.3 and 1.2. One could well ask whether the higher case fatality rate in the Negro in the South is not due to

poorer reporting of cases in this region. The fatality rate for different age groups is also of interest, although interpretation is limited here because of the meagerness of data. For both races, North and South, the fatality rates are higher under 5 years of age. This is very well shown for the white population. The data in Table VI seem to show, however, that in both regions the rate is higher in Negro than in white children under 5 years of age.

It has been repeatedly said that scarlet fever is less prevalent in the South than North, and less in the Negro than in the white population. The data in Table VII do not seem fully to support these contentions. It is true that for both white and colored the morbidity rates are lower for the South than North; however, the white morbidity rates are very low in the 4 southern states; but in the 9 southern cities, the rates are very nearly as high as those of the 6 northern cities. Turning to the differences between the two races, it is found that in the southern states and cities this is quite marked. For the southern cities as a group, the

* 1932-1933

† 1931-1933

morbidity rate is 6.2 times higher than that of the Negro, while for the southern states the ratio is 13.1 to 1. On the other hand, this does not seem to be the case in the northern cities. The ratio of white to Negro morbidity rate in these 6 cities is only 1.5 to 1. Thus, as with the mortality rate and the case fatality rate, the morbidity rate shows the greatest inequalities in the southern states, less in the southern cities, and least in the northern communities. It is also to be noted that there is as much disparity between the morbidity rates of the northern and southern Negro as between the southern white and Negro. The rates for the Negro in the northern cities were on the average 4.8 times

higher than that of the Negro in the southern cities, and 25.2 times higher than that of the Negro in the 4 southern states.

The distribution of cases according to age groups does not seem to show any essential differences between the two races. The only noteworthy fact in Table VIII is the concentration of cases not in the 0-5 year group as would be expected on the basis of the concentration of deaths, but in the age group 5-9 years. From 40 to approximately 60 per cent of the cases of scarlet fever fell in this age group in both races and geographical areas. The uniformity of these percentages is rather striking. Thus, the opinion of Doull that the concentration of deaths in the younger ages in the South may be partly due to a concentration of cases in this period does not seem to find support in Table VIII.

DISCUSSION

The marked differences in the mortality and morbidity from scarlet fever in the white and Negro population in the South have led investigators to state that this disease is not common in the Negro and that therefore he is highly resistant to it. This resistance has been explained on the one hand on his resistant ectoderm,⁵ and on the other hand, on the assumption of a longer racial experience than that to which the white race has been subjected.⁶ These two explanations, however, do not seem to hold true when two facts are considered. In the first place, our data show that although there are great differences in the South, there is in the northern cities very little inequality in the mortality and morbidity rates from scarlet fever in the white and colored populations. If the Negro were highly resistant to this disease, even though his mortality and morbidity in the North and South might not be similar, the disparity between the two races

would be just as great in the North as in the South. This has not been shown in our data.

Secondly, the idea of racial susceptibility must be discarded when the results of Dick test surveys are considered. Pevaroff and Hindman⁷ in Cleveland, Smythe and Nesbit⁸ in Gary, and others have shown that there is no significant difference between reactions of white and Negro children to the Dick test.

The recorded low mortality and morbidity from scarlet fever in Negroes in the South may be explained on two facts—(1) the occurrence of very mild and subclinical cases which are not recognized and not reported; and (2) on the very poor reporting of typical cases and deaths in the rural areas of the South where almost 70 per cent of the southern Negroes are to be found.

That very mild and atypical cases of scarlet fever must occur widely in

the South draws support from the results of Dick test surveys made in certain tropical countries. Doull⁹ in Rio de Janeiro, Dubois¹⁰ and Van Slype¹¹ in Belgian Congo, and Nazario¹² in Puerto Rico, have shown the higher prevalence of negative Dick tests and the earlier appearance of this immunity in children in the tropics. No differences were found between Negroes and whites. Mayer and Davison¹³ have similarly shown that although in North Carolina, the number of cases reported was less than half that in New York City, yet the rate of susceptibility was much lower than that found in various other comparable groups in the United States. Thus, it must be assumed that there is a wide prevalence of mild and atypical cases in the South.

Of more importance in accounting for the low recorded mortality and morbidity from scarlet fever in the Negro in the South is the poor reporting of

cases and deaths of typical scarlet fever. It was noted in our data that more cases and deaths were reported in the southern cities than in the states. Lack of medical facilities must account in a large measure for this disparity. Seventy per cent of the Negroes of the South live in the rural areas, and it is in these regions that the lack of hospitals and physicians is greatest. For example, the 4 states, Pennsylvania, Ohio, New York, and Illinois, with a population of about 2,000,000 Negroes, have 900 Negro physicians; while the states of Georgia, Mississippi, Alabama, and North Carolina, with twice as large a Negro population, have but half as many Negro physicians. In the United States as a whole, there is 1 physician for every 785 persons, but in the State of Mississippi, there is only 1 Negro physician for every 14,000 Negroes.¹⁴ Thus, many typical cases and deaths from scarlet fever must occur in the Negro which are not seen by physicians and, therefore, not reported.

Poor reporting of deaths and cases in the Negro in the South is substantiated from another angle by the investigations of Puffer¹⁵ and Gover.¹⁶ Puffer states that there seems to be marked incomplete registration of colored deaths in the rural area as shown by the large variation in the colored death rates in the counties of Tennessee. She also observes that in 15 rural counties of West Tennessee where the colored population is large, 17.7 per cent of the death certificates were not signed by physicians, and, further, that the colored death rates from ill-defined and unknown causes of death for 1933 for Mississippi, Alabama, Tennessee, South Carolina, Georgia, and Arkansas were over 100 per 100,000 population. Thus, in Mississippi, the cause of death was unknown in 1 in 5 deaths. Discussing this same fact, Gover states that the

rate for ill-defined causes for 1931-1933, in 14 southern states, for the age group under 5, was 4 times higher in the Negro than in the white.

SUMMARY

1. The differences in scarlet fever mortality and morbidity rates between the Negro and white is greatest in southern states, and least in northern cities. In the latter, there is very close approximation between the Negro and white rates.

2. The case fatality for all ages seems to be higher for the Negro in all communities both North and South. This is true particularly in the age group under 5.

3. The concentration of deaths for Negroes and whites in practically all communities is in the age group 0-5 years while the cases are concentrated in the period 5 to 9 years. There are no significant differences in the two races.

Control of Syphilis in a Southern Rural Area*

A Preliminary Report

L. E. BURNEY, M.D.

*Passed Assistant Surgeon, U. S. Public Health Service,
Brunswick, Ga.*

THE purpose of this program is to determine the most effective method of controlling syphilis in the southern rural Negro. Has the mobile clinic a place in such a program? Does it have an advantage over the stationary clinic? What is the most efficient way to obtain blood tests on all inhabitants? Do case finding and case holding activities prove worth while with the southern rural Negro? If so, what kind of worker can do these best? Can these Negroes be taught the facts about syphilis, and if so what are the best methods?

The U. S. Public Health Service in coöperation with the Georgia State Department of Health and the Glynn County Board of Health established this program in September, 1937, in an attempt to answer these questions. Effective control programs already had been established for white people in some of the northern states. No such program for the Negro was in progress in the South. Yet the South has a large Negro population—25 per cent—1 out of every 4 of whom has syphilis. The solution of this Negro health prob-

lem is essential if we hope to control syphilis in the United States.

LOCATION OF PROJECT

Three coastal counties, McIntosh, Glynn, and Camden, in southeast Georgia were selected. They comprise a District Health Department in which a syphilis program had been in progress for several years. The office of this department is in Brunswick, the county seat of Glynn, the center county.

The population of the 3 counties is 31,491, of which one-half are colored. Approximately half of this population is in Brunswick.

The land consists chiefly of pine woods and swamps, sparsely settled. Very little farming is done. Outside of Brunswick, the chief industries are turpentine, lumber, and fishing.

There are no large towns. The settlements are mainly centered around the turpentine camps. The Negroes live off the highways, back in the woods for convenience to work. This makes transportation one of the chief difficulties in providing these people with treatment for syphilis.

SYPHILIS CONTROL PROGRAM'S

PERSONNEL

One physician administers the program and operates the trailer clinics.

* Read before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

Accompanying him are one white nurse and one Negro nurse. The white nurse prepares and assists in the administration of neoarsphenamine. The Negro nurse gives the intramuscular injections of bismuth under the supervision of the assistant physician. Both nurses give diphtheria toxoid, and typhoid and smallpox immunizations, take blood smears for malaria, dispense atabrine, and collect specimens for hookworm.

The follow-up personnel consists of 1 white female, 1 white male, and 2 Negro nurses.

There are stationary clinics held in Brunswick, on the islands of Sapelo, St. Simons, and Sea Island. These are cared for by the Commissioner of Health with the aid of a contract physician and 2 nurses. These clinics take care of the larger centers of population, leaving the more sparsely settled portion for the trailer clinics. Two stenographers complete the personnel.

THE WAY WE BEGAN

A one day census survey of sources of treatment in the three counties was completed. Four hundred thirty-seven cases of syphilis were reported as being under observation or treatment during the survey period. The rate for syphilis was found to be 5 times as great in the colored race as in the white. In the white race, the rate for the two sexes was practically the same; while in the colored race, the female showed 35 cases per 1,000 as compared to 28 cases per 1,000 for the male.

The difficulty experienced in holding patients with syphilis under treatment was well illustrated by this survey. The majority lapsed before the end of the first year and in no case had a patient received minimum protective therapy (at least 20 injections of arsphenamine with 20 injections of heavy metal). Only 6 per cent had received as many as 20 injections of arsphenamine.

The private physician was treating only 12 per cent of the cases of syphilis and these were in the hands of 45 per cent of the physicians. It was found that 95 per cent of the Negro patients were in the clinics and but 67 per cent of the white patients.

Next, we interviewed the leading citizens in all the communities, the owners of the turpentine stills, lumber camps, and shrimp fisheries, the superintendents of the other industries, Negro preachers, Negro school teachers and Negro midwives. Our program was explained to them. Their assistance and coöperation were requested.

Ten clinic locations were selected as a beginning, using Brunswick as our base. Posters advertising these clinics were distributed all over the three counties. They were tacked upon churches, stores, telephone poles, and similar places. They were given also to grocers and butchers to give out with purchases. Negro preachers announced the clinics from the pulpit. Negro ministers and teachers have given us splendid coöperation and have been of invaluable assistance in our program. The news spread quickly as soon as our clinics began.

Shortly after, we arranged meetings at the various Negro churches, usually on Sundays. We would tell the essential facts about syphilis and the importance of having a blood test. Occasionally a movie was presented in an attempt further to illustrate these essential facts. However, we have not found any movie on syphilis suitable for a Negro audience. Movies available are not simple and plain enough for them to understand. The viewpoint must be different and the dialogue done in their own language.

After the meeting, we took blood tests on all the congregation, with the preacher setting an example. The church meetings are of more value from an educational and publicity standpoint

than for the actual number of blood tests taken. We have found that house-to-house canvassing by a Negro nurse to obtain blood tests is much more efficient. More persons are tested, very few are missed, and it is more economical. One nurse can go out even in the sparsely settled regions, in the woods and swamps and obtain an average of 40 blood tests a day.

There are other advantages to the house-to-house canvass. The nurse can assist very greatly in educating these people while she is taking the blood tests. Then, too, immunizations against diphtheria, typhoid, and smallpox can be given, combining syphilis with a general health program.

Every colored school in the three counties was visited and blood tests were taken on the children. All food handlers in the Health District must have blood tests before they are issued work cards. The larger industries in Brunswick have been practically unanimous in requiring blood tests on all employees.

As we progressed, we found clinics were needed in more places, and that one or two places we had selected first were not well situated. So, slowly but progressively, we have established new clinics until at present there are 24 trailer clinics held each week, traveling 500 miles. Some of these require an hour and a half, others shorter periods, depending upon the number of patients. We have been unable to establish clinics in certain small communities because of lack of time. At some of these, a Negro patient with a car will bring some fellow patients. Many times, the trailer will pick up the patients along the road and take them to and from the clinics. In one community, we have arranged for a school bus to make a circle of about 30 miles in order to collect patients and bring them to a central meeting place. This service has not only increased the attendance at this one clinic but has

decreased the number of lapsed patients.

OUR PROGRAM

Our first concern was to find the syphilis. We did this through blood testing as explained previously. Whether the test is taken on the trailer, in the home, or in the factory, we send individual letters to all persons, telling them whether their blood is good, bad, or doubtful. If doubtful, we request that they return for another blood test. If their blood is bad, we ask them to report to the nearest clinic, giving the day, time, and place. When the test is negative, we ask them to return in three months for another test. A surprisingly large number are returning.

The letter has several advantages. In the first place, we have found that more persons come in for treatment after receiving a letter than if they are told, when taking the test, to return a week later for the result. The letter does have a psychological effect, too. They like to receive letters, just as we all do, and particularly in a large, official looking envelope. They show it to their friends. They carry it around with them for weeks. It forms an impression upon them and even more important, makes and keeps them *blood test conscious*. Finally, it impresses upon the patient the result of the test. So many times a patient will say he had a blood test some time ago but either the doctor or clinic did not tell him the result, or, what happens more frequently, he did not go back. We believe our letter eliminates this complication. These letters take considerable time and effort to prepare but we are convinced from our limited experience that they are more than worth the trouble and expense.

The patient's history is taken, a physical examination is made, and he is placed under treatment. The physician attempts to obtain the source of infection and all contacts. To learn

the source is practically impossible. The majority of our cases are latent. Primary and secondary syphilis are rare. Naturally, as promiscuous as these people are, it is impossible to obtain the source of an infection obtained 2, 4, or 10 years ago. We do get marital contacts and extra-marital contacts of recent months. They cannot or will not remember contacts very far back. All sources and contacts are investigated and brought in for examination. We concentrate on those of the infectious cases but where there is time, we obtain the late latent contacts too.

Naturally our aim has been to find the early, infectious cases and give them a minimum of 20 each of arsenical and bismuth injections in order to render them permanently noninfectious. If they remain under treatment, we will attempt to obtain a cure, but our main objective is sterilization of the infectious man or woman.

Following the examination of the patient, the physician attempts to instill in him a few facts concerning syphilis—what the disease is, what happens from little or no treatment, and what consistent treatment will accomplish. I am afraid that in the majority of cases these little talks fall on deaf ears. Their reply is always "yas suh, yas suh," but one can almost feel that they do not comprehend what has been said. To supplement this talk, we give each patient the pamphlet prepared by the U. S. Public Health Service, *Syphilis, Its Cause, Its Spread, Its Cure*. Frankly, I do not know how much good this does. They all say they read it and understand most of it but they ask very few questions, which makes one doubt that they really have read it.

Force is used to hold patients in only three groups and one of these indirectly. All food handlers with syphilis must take treatment or lose their work card. In one small town we

received unasked assistance from the mayor. He became interested in our program and requested us to inform him of any patients in his city who refused to take treatment. We gave him the names of a few incorrigible ringleaders. He sentenced them to jail or to the clinic. They chose the clinic. This has had a beneficial effect upon the other patients in this community.

Through midwives we obtain blood tests on all pregnant women and treat those found infected. All midwives are licensed in Georgia. Failure to coöperate with us would mean a revocation of their license. We had one midwife bring an 8 months pregnant woman 14 miles to the clinic and they walked all the way.

We are often asked if the Negro does not dislike to come to a public clinic which advertises the fact that he has syphilis. Fortunately, the Negro is not so hypocritical as the white, or perhaps one might say that his moral code is not so stringent. Then, too, many do not relate "bad blood" with sexual relations, so there is no stigma.

They find out they have bad blood. Many are disappointed if their blood is good and want treatment, regardless. They all have a misery some place. They blame this on the bad blood. The treatment does act as a general tonic. They feel better and credit the shots. We are satisfied not to dispel their belief as long as they will continue treatment.

They really like to come to the trailer. It has become a social function with them, next to the church. There is a distinction for them to come into this clinic on wheels and receive treatment. It has a definite appeal. Then, too, they all like some medicine and they like it all the more because it is free.

The trailer was disabled for 4 weeks because of an accident. We arranged clinics in schoolhouses and churches,

but our patients dropped off very greatly. They returned as soon as the trailer was repaired. We believe that this is conclusive proof that the mobile unit has an advantage over the stationary clinic, at least with this group of patients.

Coöperation with the private physicians in the three counties forms a part of our program. This coöperation consists of consultation service, darkfield and serological examinations, free Keidel

tubes, free neoarsphenamine and bismuth for all cases, pertinent literature, particularly the supplements to *Veneral Disease Information* and, finally, a subsidy for the treatment of white indigent infectious cases and pregnant women.

We have found the physicians passively coöperative. Negro syphilis patients are poor pay; physicians would prefer we treat them. Only a few take advantage of our free drugs and sub-

Total	5,392	1,353	25.1	6,600	1,782	27.0	11,992	3,135	26.1

sidization for white indigent infectious cases. However, more are sending patients for darkfield examination to us and we are called in more frequently for consultation. It is probably a matter of education and gradual realization of the assistance we can give.

Only two physicians in the three counties verbally object to our program. They feel that these Negroes, whose average wage is but \$6 a week, can afford to pay them \$2 to \$3 a week for anti-syphilitic treatment. Their criticism is sincere and frank, and we try to cooperate with them whenever possible. They have not injured our program in any way, however.

A recent addition to our program has been an attempt to obtain serological tests for syphilis on all the white people in the three counties. We began with one county. Public meetings were arranged at the larger centers of population under the sponsorship of the Parent Teachers Clubs of these communities. These meetings were advertised in the usual way, with posters, circulars, newspaper advertisements, and an article in the weekly newspaper by the president of the local Parent Teachers Club. In addition ministers announced the meetings from the pulpit.

We presented the slide film, "For All Our Sakes," and then talked to them very briefly about syphilis and why

they should have a blood test. Suitable literature was also distributed. No attempt was made to obtain blood tests at these meetings. However, those attending were informed that nurses in a house-to-house canvass would come to their homes within the next few days for this purpose.

The meetings were well attended. The people were interested. Refusals of blood tests were rare. Sixty-six per cent of the adult white population of the entire county were examined. Less than 2 per cent were positive. We sent individual letters to these people just as we had to the Negro patients.

Several weeks after we completed our canvass, a white mother brought her 12 year old daughter to the trailer and asked if we would take a blood test on her. She explained that the daughter had been away at the time of our survey.

We have begun a similar program in a second county and the results so far have been equally encouraging. We hope to make the entire population just as blood test minded as they are vaccination minded.

WHAT HAS BEEN ACCOMPLISHED

Eighty per cent of the Negro population in these three counties have been tested. Table I gives a statistical analysis of these blood tests for the

Classification of Negro Syphilis Patients in Three Georgia Counties by Age and Stage of Infection

Stage of Infection	Age of Patient							Total	
	0-10	11-15	16-20	21-30	31-40	41-50	51-60		Over 60

Classification of Negro Syphilis Patients in Three Georgia Counties by Age and Stage of Infection (Per cent)

[illegible]

first 9 months. Twenty-five per cent of the males and 27 per cent of the females of all age groups were found to have a positive test for syphilis, giving a total of 26 per cent positive. This includes every Negro school child in the three counties, which naturally brought the positive percentage down considerably. Taking only those 16 years and over, the percentage of positive serology increases to 33 per cent. Figure 1 presents in graphic form the results of the blood tests by age groups

in each of the three counties. The females of one county in the 20 to 40 age group showed 47 per cent positive.

Glynn County coöperated in the Rosenwald Study of Syphilis in 1930. It is interesting to note that they found, as a result of their serological survey, 26 per cent positive. We found, in the same county, 7 years later 27 per cent serologically positive for syphilis.

Seventy-seven per cent of those found to have a positive serology for syphilis were brought in for examination and

Figure II

SYPHILIS PATIENTS ATTENDING CLINICS IN MCINTOSH, GLYNN AND CAMDEN COUNTIES, GEORGIA, DURING 1937 - 1938

treatment. Figure II presents graphically the increase of new patients and the increase of total patients in the three counties since the trailer clinics began. Twenty-two hundred fifty-eight Negro patients were examined and treated during the past 11 months. The classification by age and stage of infection of these patients is given in Table II.

Eleven hundred and fourteen patients lapsed from treatment, excluding those that moved away, died, or were dismissed from the clinics. Sixty-eight per cent of these lapsed patients were returned to treatment. The chief reasons for lapse are:

	<i>Per cent</i>
Employment	23.7
Lack of interest.....	15.8
(Had no real reason)	
Illness	14.0
Treatment discomfort.....	11.6
Intramuscular injections of bismuth..	9.9
Inconvenience to clinic.....	9.8
Out of town temporarily.....	7.8

Case holding constitutes our greatest problem. We are hoping that education may eventually lighten the load of the follow-up worker.

OUR CONCLUSIONS THUS FAR

1. The mobile syphilis clinic has a definite

place in the control of syphilis among the southern rural Negroes. We believe it has many advantages over the stationary clinic. A large amount of territory can be covered. Clinics can be held where there would be no available place for a stationary clinic. The ease and swiftness of operation is a decided advantage, less than 5 minutes to set up and 5 minutes to close up. There is the added advantage of convenient examination and treatment facilities. Negro patients like to come to the trailer for treatment. Other health measures can be combined with syphilis, particularly immunization. It makes a good advertisement for general health programs and aids materially in health education. Finally, the mobile unit is economical. It has cost an average of \$52.52 a month for gasoline, oil and washing.

2. We believe that the house-to-house canvass for obtaining blood tests is the most efficient method of finding syphilis.

3. Case holding is essential to the success of this program; case finding less so because we find our syphilis in the house-to-house serological dragnet. We believe also that the successful follow-up worker is a type rather than a result of education or training, at least for work among the southern Negro. It is probably more efficient to have a nurse of this type than a social worker because she can combine general health work with syphilis.

4. We believe that the Negro can be taught, slowly, the facts about syphilis and the necessity for treatment. This can best be accomplished by talking movies, simple literature, and through Negro ministers and school teachers. The movie is probably our best medium for education of the Negro, but, unfortunately, there is no movie at the present time suitable for such an audience.

Public Health Nursing Program of the Future*

GEORGE C. RUHLAND, M.D., F.A.P.H.A.

Health Officer, District Department of Health, Washington, D. C.

IT was the late Dr. William Welch who listed the public health nurse as one of the outstanding contributions which America has made to the cause of public health. It is safe to say that there is not a health officer today who does not gratefully echo this evaluation. Certain it is that the public health nurse has become a central figure in the modern public health campaign.

While it is relatively easy, from past experience and present performance, to arrive at an evaluation of the public health nurse in the general picture of today's public health program, it is not so easy to say what the future of the public health nurse in this picture will be. In fact, it would be folly to attempt to predict the future with any degree of finality. However, reviewing the development of the public health nursing service, there appear several rather suggestive changes in the application of this service which may serve as indices for possible future changes.

First, we note the recognition of the need for more than the traditional bedside care. The patient is best helped if he learns to help himself. This calls for the instruction of the patient in the

essentials of personal hygiene and instruction in the specific requirements outlined by the attending physician.

To the city of Boston, in this country, must go the credit for recognizing this opportunity in visiting nurse service and for being first in the field by establishing the first "Instructive District Nursing Association" in 1886 expressly for this purpose.

From then on, as Winslow¹ has pointed out, "We find the teaching of hygiene as a recognized objective for the district nurse along with the care of the sick in their homes."

With the extension of medical science, especially the discoveries in bacteriology and the development of societies organized for the purpose of applying this newer knowledge for the study and prevention of various health problems such as tuberculosis, infant and maternal mortality, etc., we find the instructive visiting nurse as the constant and increasingly important coworker of the physician.

Inevitably, as the various special health problems were attacked, nursing service developed *pari passu* into as many specialties.

We find, accordingly, the nurse specialist for tuberculosis, for infant welfare, for maternal welfare, for school medical supervision, for communicable diseases, for preschool serv-

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

ice, for mental hygiene, for dental service, for cancer control, for industrial hygiene, etc.

This trend toward undue specialization in the activity of the public health nurse brought about the next major change in the service of public health nursing. It was recognized that the visiting of several specializing nurses in the same family was not only uneconomical from an administrative viewpoint, but was also apt to prove confusing and, at times, irritating to the family.

Furthermore, the nurse specialist, by intensifying her attention on just one particular problem was likely to narrow her viewpoint and so overlook other health needs of the family which obviously could, and should, have been dealt with at the same visit.

The reaction to these criticisms of specialized public health nursing found expression in the present form of the generalized educational system under which the visiting nurse is to attend to all of the public health nursing problems in a district of not more than 2,000 population, dealing with the family as a whole.

The future of the public health nursing program calls for consideration mainly of two points, namely, the quantitative and the qualitative needs of the service.

Taking first the quantitative needs of the public health nursing service, one comes readily to a conclusion. If the present ratio of one nurse for each 2,000 of population is sound and justified then the expansion of the service is clearly indicated since it appears that the prevailing ratio in urban communities is about 1 to 4,000 population, and rural areas have nursing service of only 1 to 9,000 to 1 to 11,000 of population.

On the basis of the indicated standard ratio of public health nurse to population there can be no question that this service needs expansion. That

this service will see expansion seems also certain. As Sigerist² points out, the history of medicine proves that, "The community will obtain the medical care it wants."

That the community or the public is rapidly becoming more and more health conscious and is becoming vocal in its demand for health service was clearly demonstrated recently in the National Health Conference held in July, 1938, in Washington, D. C.

Significant too is the endorsement which the American Medical Association has given to the general expansion of public health service, including nursing service.

While popular demand as well as endorsement by the medical profession gives reasonable assurance for the quantitative or numerical expansion of the public health nursing service, there is no similar definite expression concerning the character or the qualitative side of such nursing service as this is likely to expand in the future.

Let me make it clear at once that I have in mind here, specifically, a declaration of plan or policy concerning public health nursing service by departments of health as the official agencies organized to render service to the public.

The existence of such bodies as the National Organization for Public Health Nursing and the League of Nursing Education is ample evidence of the keen interest which the nursing profession is taking in the development of its service.

These organizations have done an extraordinarily fine job in developing³ public health nursing in this country and through their work have given this service the important keystone position which it justly occupies in the structure of present-day public health service.

It is, however, not with the detail of nursing technic that we are concerned here, but rather with the broad plans and policies of health departments in

utilizing nursing service for the protection and promotion of the public health.

Quite obviously, as medical science will add to its discoveries in dealing preventively or curatively with problems affecting health and life, the public health nurse will undoubtedly have her part in the program of service so far as this properly becomes a matter of public concern.

So, for example, venereal disease control, child guidance, the nutritional diseases, allergic disturbances, heart disease, and many other of the so-called chronic diseases, no doubt will increasingly see the participation of the services of the public health nurse.

In all of these activities there is represented merely an extension of service and not a change in the general policy that governs present-day public health nursing.

The most significant change that, in my judgment, will characterize the future program of public health nursing, so far as official agencies are concerned, will be in the resumption, or rather the extension of bedside care.

There is little doubt that in the development of the generalized educational plan of public health nursing now so generally followed by public health departments, the tendency has been to swing too far toward the purely educational approach and to omit more or less, if not entirely, the practical bedside care of the patient.

No doubt the development of this trend sprang from necessity rather than from a deliberate choice.

Bedside care, obviously, is quite time-consuming and nurses for public health agencies were hard enough to get. Furthermore the availability of the voluntary agencies who (fortunately) carried on the traditional bedside care service, created a tempting opportunity to try out the possibilities of the educational approach in public health problems.

The importance and value of instructing the patient and the family in what to do for themselves has been clearly demonstrated; there must be no neglect of this feature in public health nursing. However, it is equally clear that a public health nursing program that means to confine itself solely to the purely educational approach by verbal instruction will no longer satisfy the public demand for service. After all, teaching by demonstration is the best teaching. The public will better understand and appreciate the value of public health nursing when this service carries with it the realization of service that is of immediate recognized comfort and benefit to the patient and family.

Public health nursing in rural areas has of necessity remained closer to the practical bedside care type of nursing. It is my opinion that public health nursing in an urban setting must likewise resume more and more responsibility in the bedside type of service.

Assuming that such a change in the practice of public health nursing in official public health agencies is likely to come about, what will be the future of the voluntary agencies that now largely function in the field of bedside care?

Public health owes its development almost entirely to the initiative and demonstrations of voluntary agencies. It is the peculiar opportunity and privilege of the private agencies to do the pioneer or experimental work; to try out the new and when the value of the new has been demonstrated, to help further to make it the responsibility of official agencies established by government, to carry out public service.

In grateful recognition of the unique and important field of service in which the voluntary agencies have functioned, and are functioning, I sincerely hope that they may continue in this rôle for the benefit of the official agencies and the public in general.

Another feature in the public health nursing service which needs further development, is that of nurses' aides, for service in the home as well as for service in hospitals.

The public health nurse, as a professionally trained person, manifestly is entitled to a compensation commensurate with the cost of the years of training required of her, and the quality and responsibility of the service she renders.

There is, however, much in the character of work required for the patient in the home or in the hospital which represents purely manual labor. As a public service it may not be justified to have the time of a highly trained and proportionately relatively costly employee taken up by manual work which may just as satisfactorily be carried out by a less costly worker.

The increased utilization of nurses' aides or of visiting housekeepers, working under the supervision of the

public health nurse, seems a necessary and desirable adjunct to the public health nursing program of the future. Likewise, with the increasing variety of service which the public health nurse will be called upon to render it will become necessary to add nurse consultants who will be specialists in their respective fields and whose particular duty it will be to assist the field nurse in dealing with special problem cases.

These, it seems to me, will be some of the changes in the public health nursing program that will be likely to characterize the future of that service.

Morbidity and Mortality Statistics as Health Information*

HUNTINGTON WILLIAMS, M.D., DR.P.H.

Commissioner of Health, Baltimore, Md.

THE public and the press are always eager to learn the latest news in regard to the general health situation in any given locality or health jurisdiction. Reports which include the figures for cases and deaths of various diseases for any given week or month almost invariably get an O.K. for publication by the city editor or his counterpart on the county weekly. Indeed, the systematic and periodic release of health information of this statistical type is a veritable cornerstone in any health education program.

Of course, the press expects the health agency supplying this material to give a local slant to the news release. There is usually a welcome for more than just the bare statistics. If a health officer or his bureau of health information makes a habit of recognizing the opportunity, comparisons with health reports from other parts of the country or the state or the county may be worked into the news release to very good effect. It has always been my feeling that a very short clipping containing nothing but figures on morbidity and mortality bespeaks a lost opportunity in the field of health education. I have wept many a tear at reading of a diphtheria death, because

the bare statistic stood alone without comment, and there was no mention of the preventive toxoid which might have saved the life of the child, if it had been given at the age of 6 months, or soon thereafter.

For a moment I would beg your indulgence in permitting me to describe what is referred to in my community as the *Saturday Letter to the Mayor* from the Commissioner of Health. I do this because of a desire to present a practical plan which has worked very advantageously for more than 20 years as a major item in the health education program of our City Health Department. The people of any community have a little more time to spend with their morning newspaper on Sunday than on any other day of the week. For this reason we always place a copy of the *Saturday Letter to the Mayor* on the city editor's desk for each of the two Sunday morning papers, as promptly as possible after noon each Saturday.

In the letter addressed to the Mayor, the Health Department, week by week, takes occasion to introduce, sometimes in quite brief paragraphs, information which it considers worthy of special public attention. This may be in the form of a warning, or an exhortation generally along "keep well" lines and associated with some disease that is prevalent or unusual. Occasionally there results nothing but the bare

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

statistics in the Sunday morning papers, and this would be expected if there were a major diplomatic crisis in Europe or a hurricane sweeping across Long Island or New England. More commonly, however, the narrative and educational material upon which attention is focused in the letter to the Mayor appears in a corresponding article of major value in community health education.

The routine of sending the Saturday letter to the newspaper offices regularly each Saturday noon is never broken and the city editors look for this particular form of news release and even send a messenger to the Health Department every Saturday to assure its safe arrival.

It has occurred to me that you would be interested in knowing the type of headings which have appeared from Sunday to Sunday as a result of these efforts in health education which are based on the weekly morbidity and mortality statistics of our community. Out of 42 clipping heads from the two Sunday papers in 1938, 12 headings dealt with syphilis and 8 with diphtheria. Others dealt with scarlet fever, whooping cough, undulant fever, leprosy, tetanus, and dysentery. Samples of these are as follows:

Syphilis Cases Listed for Week Set Record.

Twenty-one Employees Asked in Drive on Syphilis.

Syphilis Control Is Under Way Here.

Syphilis Case Reports Double Previous Years.

Seven Diphtheria Cases Reported Here for Week.

Diphtheria Takes Its First Victim of Year; Inoculation Stressed.

No New Diphtheria Cases in Week.

Whooping Cough Death Cited in Health Report.

Undulant Fever Case Is Reported.

Leprosy Case Is Reported in Baltimore.

The system described in making use of morbidity and mortality statistics by this weekly report to the Mayor and the press, in reality is a method of carrying out actual provisions of the

City Charter and Ordinances which require the Commissioner of Health to keep the Mayor informed in regard to the health conditions of the community. The *Saturday Letter to the Mayor* was established by my distinguished predecessor, Dr. C. Hampson Jones, who was closely associated with the public health service of our community for a period of 36 years. It has become so automatic that it protects the Health Department itself from overlooking important items, omissions which might otherwise lead to some embarrassment. I would like to give you just one experience in this connection.

Some years ago we had a case of leprosy and, pending the confirmation of the diagnosis, the case was not recorded in the weekly statistical table. We had a very coöperative city hall reporter representing the press and I persuaded him to postpone public mention of the case of leprosy until I gave him a "go ahead" and he promised to coöperate in what I considered a most unusual manner. It was my hope to arrange with the U. S. Public Health Service for the transfer of this case to the federal leprosarium in Carville, La., and have the patient on his way before the news release was issued. A week later a Sunday morning headline reported the case of leprosy prior to my having said anything to my friend the city hall reporter and I was much disappointed. I reminded him that he had promised to hold this release and he smiled and told me that the case, after the diagnosis was confirmed, had automatically appeared in the statistical table which had reached the press *from my office with the usual Saturday Letter to the Mayor*. So you see the routine nature of this particular weekly news release is better even than the Health Department from which it comes and this incident has given us a good deal of comfort by way of assurance that no important health information is

likely to be withheld from the public.

There are many types of newspaper articles that have resulted from the *Saturday Letter to the Mayor* based upon statistical material and accompanying educational information. Food poisoning outbreaks, lead poisoning incidents, care in the handling of crab-meat and the necessity for the "pasteurizing" or reheating of custard-filled pastries have all been reflected in the public press in our community and in many instances directly because of the *Saturday Letter to the Mayor*. On the other hand, special items of public health interest, with educational information spread not too thickly, as in a sandwich, are given to the city editor over the telephone or by written individual or weekly or monthly news releases. Some of these result from our Tuesday morning radio broadcast or the periodic monthly appearance of *Balti-*

more Health News. The broadcasts are always under the joint auspices of the City Health Department and the State Medical Society, known in our state as the Medical and Chirurgical Faculty of Maryland.

It has been learned by experience that an extensive scrapbook and clipping book is of the utmost value if kept over the years, and our file of *Saturday Letters to the Mayor* is constantly in use as source material in health education.

In this discussion no effort has been made to cover the assigned topic in any complete manner. Rather I have sought to present for your consideration a particular routine procedure, aimed at making use of local vital statistics in a basic health education program, a procedure which has more than proved its usefulness in my own community.

The School Nurse as a Health Educator*

GERTRUDE E. CROMWELL

Supervisor of Health Education and School Nursing, Des Moines Public Schools, Des Moines, Iowa

SCHOOLS are basically educational agencies. If the purpose of all education is to help each individual to acquire the intelligent art of living fully and well, then whatever health work is sponsored by a school system should be of an educational nature. Such education will fail to function unless the principles presented to the learner are accepted by him as important to his welfare, and unless he willingly puts what he accepts into use. Functional education is one of the slowest processes known and frequently health workers grow impatient. They then turn to peddling out service or resort to coercion to accomplish the results they are seeking.

If we were to analyze the factors which are important to health, almost at once we would note the environment as one of the most important. The child at school, as well as the child at home, must depend upon the adults in his home and community to provide the type of environment in which he can best grow. The child has very little influence over his mode and place of living, so in spite of what the school teaches him about environment, he

must still depend upon those older than himself to provide the material needs of his life. The school can first provide within the school the best physical environment possible and then teach both children and adults of the community what constitutes a satisfactory environment and how improvements can be made. The school has no coercive rights to force changes in modes of living. Palliative measures will not, in the long run, pay such dividends as will the slower processes of real education.

Another factor in the child's life which most of us concede as of vital importance to him, and upon which most of our present health education has been based, is the group of so-called health habits. Habitual health practices tend to develop in proportion to the adequacy of the equipment provided, sympathetic encouragement for, and the amount of insistence upon regular performance of a given task. Again, the adult is responsible for these and, at best, the school can only assume its responsibility for seeing that those health practices which need to be followed by the child while in school are followed, and to give a limited amount of information to the child about health behavior. To overstress health teaching when health promoting practices are impossible, more frequently than not, re-

* Read at a Joint Session of the American School Health Association and the Public Health Nursing Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

sults in a negative reaction to the whole régime. In the course of a 9th grade boys' hygiene class, one lad made a remark that his mother would like to feed the family correctly. He said that she read menus and then realized she could not afford the foods mentioned. The boy was frankly discouraged.

A third factor brings us to the area of much confusion in thinking and, therefore, to much disagreement in policy. This consists of the prevention and correction of defects, infections, and sources of strain. Certainly, in the face of the present national dilemma on medical care, few would dare to express an opinion as to what the school will be asked to assume in its future health program. Personally I hope that the schools may be asked to keep their activities within the original bounds of education. I am not suggesting that the schools take a side in the controversy but as resources and new avenues for additional health care are developed through other community agencies, the schools shall teach people how to make use of these facilities.

Health education is, at best, only partially successful unless the end result of the health program is a satisfactory emotional attitude of the individual toward his limitations as well as toward the potential abilities placed upon him by heredity and environment. This may be termed mental hygiene if you wish. The school should recognize that there is a great problem in an individual's adjustment to an unpredictable social environment. School people are too prone to think that wonders can be accomplished in the 6 hours of the school day. I am not so optimistic. What happens during the other 18 hours of the day may enhance or undo the work of the school. This depends upon the degree of functional education the school has been able to accomplish not only with the child but with the adults who manage the child's world.

THE CONTRIBUTION OF THE SCHOOL NURSE TO THE SCHOOL HEALTH PROGRAM

Usually about the only full-time health worker found in schools is the school nurse. Her 3 years of basic hospital training is apt to have made her a follower instead of a leader, hence her advanced preparation must offset this psychological attitude. Upon entering school work many nurses feel inferior to the teachers in spite of the nurses' superior knowledge as to what makes for health. The nurse has already, or soon learns, the technics of measurements which are used in determining some of the aspects of health. These include sight and hearing tests, weighing and measuring, and the technics of recording her own or the physician's findings of the deviations from normal body structure. She also has learned how to do a good job of taking care of the children and frequently finds it easier to take care of the child herself than to teach someone else to do it. Too frequently she is unwilling to let neglect exact its just toll. She fears the danger to life. However, one might well ask what happens to the child during the other 18 hours of the day outside of the school, unless the child or his parent knows what to do. Experience under guidance is an excellent teacher.

A school health program based on health education needs personnel prepared to see in their work many educational possibilities. A big problem of a school system, which desires to base its health program on education, is to find a nurse prepared not only in the routine work as given above but who can also measure up to the following standards:

1. The nurse shall be able to evaluate the educational assets and weaknesses of each of the routine procedures which she is required to do. For instance, she shall see the educational meaning when she weighs a group

of children, or the educational handicap of the deaf child.

2. The nurse shall know what community resources are available which, if put to proper use, may make the life of those with whom she deals more worth while.

3. The nurse shall know how to compile her records in such a way that the community shall know the health needs and status of the school population. She shall know how to teach key people about what she has found and how this knowledge may be used most wisely.

4. The nurse shall know when to shed responsibility on to the shoulders of its rightful owner. She is not a prop but a guide to a more self-sufficient life.

5. The nurse shall know how to make each contact with a child, a teacher, or a parent of real value, in that the individual feels better able to cope with the situation should it again occur.

6. The nurse shall evaluate all she does as to its real worth, eliminating all "busy work" done to fill in time and tending to pad reports, and shall create, when necessary, new and better ways of doing her work.

In conclusion, a nurse with certain routine duties to perform will produce findings which should be of real value to somebody else in the school system. The findings themselves are valueless until someone uses them. The nurse is responsible for finding that which is good or bad as it relates to health, but the changes necessary for betterment are usually the responsibility of somebody else. The nurse is a health educator only when she can get others to assume their responsibilities.

Balancing Our Health Budget

"In connection with balancing the budget, Mr. Chairman, I hope that this Congress will give more attention to balancing our health budget. It is cheaper to keep a woman from dying in childbirth than to take care of the orphans in an orphan asylum or to give aid to the dependent children. It is cheaper to aid in building tuberculosis sanatoriums than it is to pay for the death from tuberculosis and the widows and children who are left. The State

Health Officer of Tennessee estimates that it costs on the average of \$150 to bury a person in Tennessee, and on that basis it is costing that state more to bury people dying from tuberculosis than for its entire health program, including tuberculosis and all the other diseases."—Testimony before the Subcommittee of the Committee on Education and Labor of the United States Senate, by Dr. Thomas Parran, Surgeon General, U.S.P.H.S.

Industry's Challenge to the Nurse^{*}

LAVONA BABB, R.N.

Quaker Oats Company, St. Joseph, Mo.

TO improve and preserve the health of the industrial worker to the extent that more complete happiness and greater individual productive capacity shall be possible—this is the challenge of industry to the nurse.

Because we are workers in the health industry, we first view the humanitarian aspect of this challenge.

There are approximately 40,000,000 industrial workers in the United States to be kept in a state of health to make possible a maintenance of living standards which will be a contribution to American society.¹ The nurse is in a strategic position to aid in the improvement and preservation of high health standards of all fellow employees and their families. How can she help?

I. By educational programs on health and safety, in order to prevent disease and injury. This program would include: mass meetings on health problems, and work with safety engineer and committees.

Literature and posters on health questions distributed to individuals, posted on bulletin boards, available in reading rooms and hospital waiting room, enclosed in pay envelopes.

Instruction and demonstrations in homes at every opportunity on questions of health, sanitation, hygiene.

II. By contacts in the homes she has unlimited opportunity to give helpful advice, establish good will and aid in adjusting social problems.

1. She may be responsible for getting the doctor on a personal case before it is too late.

2. She will assist in securing aid, if needed, by reference to proper agencies, and see that the employee understands functions of community agencies.

3. The nurse's opinion may be valued highly by employees; for to them she is more than a professional person, she is, by her closer association with them, more of a friend. They trust her judgment and may rely more on her advice than any other, therefore, she must be worthy.

III. The cooperation of industrial medical units with city and state health department programs and their interpretation to the management will be an aid to improvement of health standards. In this, as in all activities, the nurse acts as an aid to the physician and must keep herself informed. Where there is no full-time physician, it may be necessary for her to interpret these programs.

IV. By helping to make the plant a more healthful place in which to work.

By plant sanitation inspections or by assisting in them and recommendations to improve sanitation (lighting, ventilation, dust control, cleanliness and elimination of all unsanitary conditions), the nurse will help to make the environment in which workers spend at least 8 hours a day, a contributing factor to better health and, consequently, better workmanship.

V. By instituting recreational programs where there are none, not only the physical but the mental health is given a boost. Clean recreation at the plant develops interest in clean recreation outside, and so keeps minds and bodies on that higher level.

VI. Probably the most important factor in building health is to know the actual physical state of the people in your plant. This is possible only by physical examination pre-employment, and at least annually thereafter, supplemented by follow-up work on recommendations made by the doctor, and by constant observation and complete records kept

^{*} Read at a Joint Session of the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

by the nurse on all corrections and additional defects discovered between examining periods.

The nurse must be able to show a worker the advantages and the returns on his investment in good health. She must, among other things, be a good saleswoman. To do this she must be a shining example and a firm believer in the thing she is selling. She must also be patient, encouraging, and persevering when trying to accomplish 100 per cent correction of physical defects.

VII. The nurse may be the go-between in rehabilitation for injured or ill workmen. With the plant physician, the personnel director, and the foreman, she aids in properly placing returned workers, both to the satisfaction of employee and employer.

ECONOMIC CONSIDERATION

The nurse is ever alert to the interest of her patients. The industrial nurse is a specialist in the field of nursing. She has not only a duty to the employee from a humanitarian standpoint, but the challenge of industry has an economic consideration.

Much of the absenteeism in industry is preventable. Knowing this is a challenge to industrial doctors and nurses. We have tangible objectives toward which our efforts must be directed.

Absenteeism must be reduced. It is expensive and inconvenient to both employer and employee.

Injury—The nurse can decrease absence due to injury; first, by putting forth her best effort in teaching, interpreting, and selling safety. Thus prevention in injury is a big factor. By coöperation with management, personnel director, and safety director, she can do much to aid in prevention.

Taking minor accident histories, recommending corrections in plant conditions, if at fault, will prevent further accidents. A good nurse may have a greater influence on the worker while treating an injury, by advising and teaching safety at that particular time, than anyone in the entire organization.

Another phase of prevention is of course the proper technical knowledge

used in treatment of injuries to prevent infection and speed recovery. Enough cannot be said here on this important subject. Every nurse recognizes the importance of proper first aid treatment under standing orders of the plant physician. Thus the severity rate can be decreased.

The nurse must be able to show the management the importance of immediate treatment of all injuries, regardless of severity, by either the *doctor or nurse* and not by fellow employees or outsiders. Disastrous results will accrue if such practices are permitted, whereas if proper immediate treatment is insisted upon, the company will benefit in decreased compensation and absenteeism, and the employee need not suffer unnecessary pain, permanent disability and loss of time.

Occupational Disease—Absence due to occupational disease is a problem every nurse must face. Here as before her first duty is prevention.

In the *Industrial Nursing News Letter*, August, 1938, the following statement was made: "Every nurse, in addition to caring for sick and injured workers, has the golden opportunity of observing conditions in the making which affect their health. If management is not informed of the hazards, whose fault is it?"²

There is a challenge!

By plant inspections the alert nurse will recognize, investigate, and recommend correction of many hazards before they have had the time to affect health. We cannot always hope to recognize such hazards, so we must be good observers and case finders. Early case finding and reporting to the plant doctor is a step toward early recovery and prevention of additional cases. This responsibility lies with the nurse.

The kinds of occupational disease reported vary in different states, due to type of industry prevalent in that area.

Also in some states certain occupational diseases are not compensable, therefore, it is impossible to make a definite statement as to that class of diseases which is most frequent. However, we know that occupational disease accounts for $\frac{1}{2}$ per cent to 2 per cent of all disabilities from industrial causes. Those ranking among the highest in a study of the States of New York and Ohio are dermatitis, tenosynovitis, and lead poisoning.³

Illness—According to a limited study made by the American College of Surgeons, in which 116 companies from various parts of the United States, employing 352,591 workers, reported in 1936 that the average worker loses 15 times as much time from non-industrial injuries and illnesses as he does from industrial injuries. Therefore we are compelled to direct every effort toward controlling disease due to non-industrial causes.

The relative frequency of diseases among 105,072 male industrial employees, in a study by the U. S. Public Health Service, 1921-1927, shows respiratory diseases 41.8 per cent. Next in rank are digestive diseases, external causes, circulatory and genitourinary, rheumatism, nervous system, skin, organs of locomotion, and epidemic and endemic diseases.⁴

In considering nursing activity to control this absenteeism, we again say prevention comes first.

Primarily maintenance of high health standards and immunization are the two leading factors in preventing disease.

Industry may not sponsor immunization programs, but by coöperating with health departments, an industrial nurse may by advice and encouragement be influential in promoting the individual immunizations needed.

Plant sanitation and teaching of health habits will aid in control of contagion and infection. This should

affect that respiratory disease rate.

Early case finding, reference to a physician, and isolation of suspected contagions should speed recovery of any case and prevent transmission of infectious diseases. Industry expects the nurse working in the plant to be capable of observing and properly disposing of cases, to minimize transmission of infections and loss of time.

Supervision of care in the home of either injury or illness cuts absenteeism. Improvement in medical science and hospital care has reduced hospitalization period one-half in the last two decades.⁵ Why then cannot scientific care in the home reduce the period of absenteeism? We know that it can.

DEBITS AND CREDITS

The doctor and nurse are those chiefly responsible for the state of employees' health. Plant sanitation, home hygiene, correction of physical defects, proper recreation, proper placement in consideration of physical ability—all these are their activities toward the goal of better health and greater production.

The benefits accruing from these activities are sometimes intangibles that cannot accurately be converted into material values. We believe that they are desirable dividends and worthy of their cost. We must prove them to be so.

According to the American College of Surgeons the smaller the plant the greater per capita medical and compensation costs (60 per cent greater in small plant). Small plants are usually lacking in proper health preservation measures. There is no regular physician but usually one on call only.⁶ The nurse in this type of plant is responsible for cutting cost. She can institute, with the advice of the physician on call, a health program with preservation measures, just as any public health nurse can do. She can in-

interpret plant sanitation to employees. If there is no doctor or sanitation engineer, she may make minor plant inspections, sell management on physical examinations, teach safety and health, do follow-up work on recommendations on doctor's examination, make home visits supervising care and teaching health and home hygiene, and keep informed upon and practice proper care of injury and illness, keep records for management showing actual dividends in health and decreased absenteeism, if not in actual dollars and cents, making them realize that it is cheaper to pay for preventive measures through organized and efficient medical and safety service, than for emergency repair service and compensation.

PREPARATION AND QUALIFICATIONS

In conclusion, the natural questions are "Are we prepared?" and "What qualifications must we have to consider meeting the challenge of industry?"

As stated by Ernest Augustus, Safety Director, The Mead Corporation, Chillicothe, Ohio, some of the necessary personality qualifications of an industrial nurse are:

Courtesy and a sympathetic attitude toward others; being neat, clean, and attractive in her personal appearance and dress; having tact and diplomacy; sincerity of purpose; good health; dependability; far-sighted vision, and ability to plan ahead; sound judgment; initiative and originality; industriousness; loyalty; supervisory ability and willingness to cooperate with others; a sense of absolute fairness in all things; coolness in times of emergency; a good common sense knowledge of human nature and how to handle people;

a pleasant voice and a kindly smile for all alike; the rare ability to be a good listener; adequate technical knowledge and ability in her profession; impeccable moral habits; and a sincere personal interest in other people.⁷

PROFESSIONAL QUALIFICATIONS AND PREPARATION

First she should be a registered nurse, with at least a high school education; be an interested member of the Alumna, State, and National Nursing organizations. If unsupervised by a public health nurse, she should have had some postgraduate work in public health, specializing in industry. She should have had some supervised experience in community public health nursing. She must know her community health agencies, and work with them. She must attend meetings of all professional organizations.

A nurse with these qualifications can hope to justify the expenditure of time and money, the trust and confidence placed in her when she takes a position and accepts the challenge of industry.

Newer Concepts and Procedures of Maternal Care*

MAUDE M. GERDES, M.D.

Obstetric Consultant, U. S. Children's Bureau, Washington, D. C.

GOOD maternal care demands that the health and life of the expectant mother be preserved and that a child shall be born alive and capable of continued normal extrauterine existence.

That such care is not generally available to the mothers and babies of this country is a fact which is accepted by all who have studied the situation. The important thing now is to determine an intelligent course of action within the means at our disposal and embodying methods which have already proved their value, but one that looks toward continuously improved facilities in communities not properly equipped at present.

Good maternal care consists of good prenatal care *plus* skilled medical and nursing care during delivery and the puerperium, and has social and economic aspects as well as those that are strictly medical.

The value of prenatal care as an essential element in good maternal care has been increasingly appreciated since 1858 when the first prenatal clinic was established by accident at the Dublin Maternity Hospital because expectant mothers were required to report early in pregnancy in order to insure them-

selves a bed in the hospital for confinement.¹ It was at this time that first general use was made of the discovery some years previously that the appearance of albumin in the urine was associated with the toxemias. Because these women with toxemias were treated early, there were fewer deaths from eclampsia.

Since that time the practice of prenatal care has been influenced by innumerable advances in every field of medicine, but here as everywhere there has been a distressing lag between discovery and application. For instance, the significance of blood pressure determinations in pregnancy, though recognized as early as 1894, is still apparently not appreciated by many physicians who care for pregnant women.

According to recent studies there is still only a small percentage of expectant mothers who receive any kind of prenatal care,^{2, 3} and an even smaller percentage who receive what can be considered good prenatal care.⁴

Death rates from toxemias of pregnancy decreased 37 per cent between the years 1930 and 1936 in this country. The increased practice of prenatal care is credited for this. But deaths from this cause still constitute 23 per cent of all maternal deaths, second only to sepsis.

Undoubtedly the lives that have been saved by good prenatal care thus far are only an indication of what can be

* Read at a Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

expected by a much more widespread application of a higher quality of care. In view of recent observations, there is good reason to believe that not only deaths from eclampsia but also a considerable share of those due to other causes could be prevented by much better prenatal care than has been generally available in the past, and by reduction in the number of abortions.

The direct bearing of nutritional status, of focal infection, of glandular imbalances, of such diseases as tuberculosis, heart disease, and nephritis, on puerperal mortality, have been subjects of much study in recent years and must be taken into consideration in any appraisal of the value of prenatal care.

The importance of the nutritional status of the pregnant woman is receiving more recognition than ever before. There is no denying the fact that a woman who is in good nutritional condition is better able to withstand the demands of pregnancy and labor. Some very significant observations on the effect of supplementing the diets during pregnancy have been reported recently, particularly in Great Britain. In 1934 in the Rhondda Urban District in Wales, the puerperal death rate, despite the *usual* prenatal care, had failed to decrease and, as an experiment, supplemental food was provided in addition to the usual care given in the prenatal clinics. I quote from the *Report of the British Health Services*⁵:

The puerperal death rate among the 10,384 expectant mothers who received extra nutrition from January 1, 1935, to July 30, 1937, was 1.64 per 1,000 total births, whereas among the 18,854 other cases in the same area the puerperal death rate was 6.15. The stillbirth and neonatal death rate among the cases assisted in 1937 was nearly 50 per cent less than that among the other cases in the same area. Other factors such as failure to attend antenatal clinics may explain a part, but certainly not the whole, of this difference.

The results of these studies are worthy of serious consideration. As a

result, in England, Wales, and Scotland, the majority of maternity and child welfare authorities are now supplying milk to expectant and nursing mothers attending clinics.

Recently attention has been focused on the etiological relationship of low protein diets to the toxemias of pregnancy.^{6, 7} This factor is of special importance in certain sections of the southern parts of the United States. The relationship of salt intake to the toxemias is also being restudied.⁸ Likewise the effect of vitamin and mineral intake on the health of the expectant mother and her baby are being given more consideration of late, as is the prevention of anemias of pregnancy by proper regulation of the diet.

Focal infection during pregnancy is receiving more attention because in the opinion of a number of observers there is a relationship between focal infection and sepsis, kidney infections, toxemias, and abortion.^{9, 10, 11}

An appraisal of the pregnant woman's endocrine system is necessary to safeguard the health of the mother and the baby. Thyroid dyscrasia is a recognized factor in habitual abortions.⁹

A serological test for the presence of syphilis early in pregnancy is now a routine procedure in good prenatal care.

Tuberculosis, heart disease, and nephritis all contribute substantially to the numbers of puerperal deaths, and a reduction of these deaths demands early diagnosis and intelligent management—a responsibility which must be assumed by the physician and nurse as part of prenatal care.

In order to make sure that the best type of prenatal care is given in clinics that are being established, careful supervision of the medical services must be provided by physicians who have specialized in obstetrics. It is encouraging to note that, of the 38 states which have set up prenatal clinics as a part of the maternal and child health

program under the Social Security Act, 25 have employed obstetricians either full-time or part-time on their staffs to give supervisory and consultation services in the maternity program. A number of states have established technical committees composed of practising obstetricians and pediatricians to help by formulating standards of maternity care and care of new-born infants.

Many of the states that are developing nutrition programs are providing nutrition services at the prenatal clinics; likewise, a few states are providing dental services at the clinics, and one state reports that tuberculin tests are being done routinely in the prenatal clinics. Wassermann tests are being done routinely in the prenatal clinics in 33 states.

In addition to the best possible type of medical care, we must recognize that in the areas where the best results have been obtained, as shown by a marked reduction in puerperal deaths, the public health nursing service has also been good. It is the public health nurse who is largely responsible for getting the women under medical care in the first place, seeing to it through home visits that they understand how to carry out the treatment ordered by the doctor, who is on the alert for danger symptoms, who sees that the patients remain under medical care. Without these services the mere setting up of a prenatal clinic is practically useless. Efficient public health nursing service makes the prenatal clinic work and get results.

CARE AT TIME OF DELIVERY

About half of the puerperal deaths are due to causes incident to labor and delivery. The provision for safe care at delivery is essential to the demands of good maternal care and whether the delivery occurs in the hospital or the home, skilled medical and nursing care must be provided. In 1936, approximately half of the two million live

births occurred in rural areas and 86 per cent of these births were reported as occurring in the home. In addition, 29 per cent of the live births in urban areas occurred in homes, making a total of a million and a quarter live births which occurred in homes. The problem of providing good medical and nursing care for these mothers and babies when the delivery takes place in the home offers special difficulties which are now more than ever before calling for solution.

A planned home delivery in competent hands may be safe for both mother and baby. By "planned" I mean that the patient has been under prenatal supervision and is known not to have any complications which contraindicate a home delivery, and preparations for the delivery have been made with the aid of a nurse. By "competent hands" I mean a conscientious physician who knows when he needs the consultation service of an obstetrician or pediatrician and where to obtain it, and a nurse who is skilled in obstetric nursing and nursing care of the new-born.

It is recognized for all primiparae, and in certain complications and emergencies, delivery care in a well staffed and equipped hospital is essential and every effort should be made to arrange it before labor begins. Wherever home deliveries are done, access to the facilities of a well equipped and well staffed hospital with readily available consultants within reasonable distance is essential if these lives are to be saved.

In 83 counties in 27 states, delivery nursing service for patients delivered in their homes by physicians has been organized. According to preliminary progress reports, there has been a substantial increase in the number of services during the past year. Methods are being worked out and it is hoped in time such service will become available in a much larger area.

This discussion has dealt largely with

the problem of care of the woman to be delivered in the home because the need to improve this care is so great and so pressing. Ideally, however, care in a well staffed, well equipped hospital should be available to all women for delivery, but obviously it will be some time before such facilities can be provided. Moreover, unfortunately, there exist today altogether too many hospitals or maternity homes where skilled consultation service is not made available, where operative procedures are undertaken without previous obstetric consultation, where equipment for good obstetric care is inadequate or lacking, where isolation facilities for the septic woman or infected infant are not provided, where highly skilled nursing care for mother and infant are not available. If the deliveries are to be increased either in existing hospitals or in new ones, as indeed seems desirable, it is imperative that responsible public authorities establish and maintain, with the advice of qualified specialists in the fields of obstetrics and pediatrics, standards of hospital care that will insure a high degree of safety for mother and infant.

The opportunity to raise standards of care either for hospital or home delivery lies increasingly in the hands of state health department officials who are responsible for maternal and child health programs.

The matter of providing obstetric and pediatric consultation services for general practitioners is receiving increasingly greater attention by the state health departments. In one state, such services are available on a state-wide basis. Though most of the projects now in force cover only a limited territory, a variety of methods are being explored with a view to determining the most practical for use under different conditions. Eighteen states employ obstetricians or pediatricians on a full-time salary basis for this purpose; in 22

states consultants are employed on a part-time basis, and in 4 states specialists may be called for consultation from an approved list by general practitioners and payment made on a case basis.

Just as we have to devise ways in which to deal with the problem of home delivery intelligently, we must face the problem of the untrained midwife and deal energetically and intelligently with it. In 1936, nearly a quarter of a million deliveries were attended by midwives or other non-professional persons. In 1938, 34 states report approximately 35,000 midwives practising. Twenty-eight state health departments now have assumed responsibility for supervising their midwives, and approximately 23,000 are so supervised. Some states are requiring that all midwives' patients attend prenatal clinics.

In Tift County, Ga., the local health department in coöperation with the State Division of Child Hygiene has set up a program which illustrates many of the features which I have mentioned. In this county, both the infant and maternal mortality rates have been high, and 42 per cent of the births have been attended by midwives. Prenatal and postnatal clinics, directed by an obstetrician on the health department staff, have been established at strategic points to give care to all patients of midwives and to patients of physicians if they desire it. A complete program of midwife control, instruction, and supervision is being developed. The obstetrician is available for delivery of all midwife cases deviating from normal and is also available for consultation to physicians on request. Home delivery nursing service is available to physicians conducting home deliveries. Services of local registered nurses at the time of delivery are utilized to supplement the health department nursing staff. Sterile packs are provided for the use of physicians in home deliveries and certain sterile sup-

plies are provided for the use of midwives. Patients requiring hospital delivery are cared for at hospitals through funds made available for this purpose by the county. Programs such as this are pointing the way for fulfillment of the demands for good maternal care for the mothers and babies of the United States.

No discussion of the subject of maternal care is complete without mention of the problem of abortion which is responsible for 20 per cent of puerperal deaths and gives indication of being on the increase. Nothing less than a concerted drive by health and welfare authorities, the medical profession, and the public working together by every means at their disposal will effect any reduction in the deaths due to this cause.

Epidemiology of Syphilis in New York City*

THEODORE ROSENTHAL, M.D., AND
JOSEPH WEINSTEIN, M.D., M.S.P.H.

*Director; and Medical Consultant, Bureau of Social Hygiene,
Department of Health, New York, N. Y.*

NO phase of syphilis control is of greater interest to the health officer than its epidemic manifestations. Epidemiology has been defined as "the study of disease as a mass phenomenon."¹ The concept of epidemiology in relation to syphilis has been broadened in recent years to include a consideration of the factors concerned with the transmission and means of prevention of spread of this disease in the community.

It has long been recognized that syphilis spreads in epidemic form. To quote Parran,² "Syphilis is an epidemic disease. It is kept alive, and spreads in the population by a series of small epidemics." One of the earliest accounts of an epidemic of syphilis in this country is that related by Governor John Winthrop³ who described an outbreak of syphilis which occurred in Boston in 1646:

"1646: There fell out also a loathesome disease at Boston which raised a scandal upon the town and country, though without just cause. One of the town () having gone cooper in a ship into (), at his return, his wife was infected with lues venerea which appeared thus: being delivered of a child, and

nothing then appearing, but the midwife, a skillful woman, finding her body as sound as any other, after her delivery, she had a sore breast, whereupon divers neighbors resorting to her, some of them drew her breast, and others suffered their children to draw her, and others let her child suck them (no such disease being suspected by any), by occasion whereof about 16 persons, men, women and children, were infected, whereby it came at length to be discovered by such in the town as had skill in physic and surgery, but there was not any in the Country who had been practiced in that cure. But (see the good providence of God) at that very season there came by accident a young surgeon out of the West Indies, who had had experience of the right way of the cure of that disease. He took them in hand, and through the Lord's blessing recovered them all () in a short time. And it was observed that although many did eat and drink and lodge in bed with those who were infected and had sores, etc., yet none took it of them, but by copulation or sucking. It was very doubtful how this disease came at first. The magistrates examined the husband and wife, but could find no dishonesty in either, nor any probable occasion how they could take it by any other, (and the husband was found to be free of it.) So it was concluded by some that the woman was infected by the mixture of so many spirits of men and women as drew her breast (for thence it began.) But this is a question to be decided by physicians."

A little more than a century later (1759) Voltaire in his immortal *Candide*, relates the story of Pangloss's infection. With astonishing prescience the droll fellow traces most

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

accurately the source of his own disease through nine or ten individuals, back to one of the companions of Christopher Columbus.

Contributions to the public health literature on the practical epidemiology of syphilis are all of comparatively recent date. The venereal disease control program has given full recognition to the great importance of epidemiologic work in the control of the disease. Munson^{4, 5} reported a series of localized outbreaks of syphilis in rural areas in upstate New York and demonstrated the practicability of epidemiologic investigation, terming his method "sole-leather epidemiology."

Smith and Brumfield^{6, 7} described excellent examples of investigation of syphilis patients in a southern rural community. They emphasized the paramount rôle of the physician in such investigations; because of the intimate relationships between physician and patient during the course of routine history taking and physical examination, an unequalled opportunity is provided for the establishment of complete confidence in the doctor.

It is possible that the above reports may have given rise to the conclusion that it is impossible to track down similar outbreaks in large cities, because of the obvious differences in population and locale. Experience in New York City as shown here and elsewhere⁸ indicates that with careful and intensive application of direct epidemiological procedures, this type of work is also possible in a metropolis. Moreover, it has been shown conclusively⁹ that epidemiological methods of investigation are applicable to syphilis patients in private as well as clinic practice.

Ingraham¹⁰ outlines the technic of approaching the patient for information as to source and contacts and stresses the superiority of the persuasive method of approach over that of coercion.

Similarly, suspected contacts submit to examination, and to treatment when infected, more readily when persuasion has been employed than where compulsion has been practised.

Kulcher and Ninnis¹¹ have described a coördinated police and social service system of case investigation at the syphilis clinic of Stanford University School of Medicine. Under this system, sources of infection, contacts and patients lapsing treatment, who have been reported to the San Francisco Department of Public Health, are investigated jointly by an un-uniformed police inspector and a social service worker. Statistics are given showing the effectiveness of this method. The authors claim that the combined method of police and social service investigation is more effective than either one when used alone.

SYPHILIS IN NEW YORK CITY

Morbidity reports do not present a true picture of the syphilis problem in New York City. However, such information as is available is of interest to the epidemiologist because it indicates prevalence and distribution of this disease in the community.

Syphilis in New York City occurs endemically with a tendency to spread in localized outbreaks. It has been conservatively estimated from a census study^{12, 13} that the prevalence rate of syphilis in New York City is about 5 per cent of the total population, with 58.5 per cent among men and 41.5 per cent among women. It is worthy of note that the number of early cases, as shown by this study constituted about 17 per cent of the total number of cases reported under treatment.

A study of reported cases of syphilis by age distribution¹⁴ showed that 52 per cent of the total number occurred in the age group 18-35, with the highest peak (20.22 per cent) in the age group 24-29.

Available reports indicate that an average of 6.5 per cent of pregnant women¹⁵ in the United States are infected with syphilis in one form or another, and that about 2 per cent of the child population are victims of congenital syphilis.¹⁶ It is felt that the same rates probably prevail in New York City.

PROCEDURES IN CASE INVESTIGATION

Health officers agree that syphilis can be eradicated by organized efforts at discovering and treating infected individuals. The first step in any effective case finding machinery is the prompt and complete reporting of every diagnosed case of syphilis. Reports of laboratory examinations for syphilis are no longer accepted as case reports by the New York City Department of Health.

The Sanitary Code requires physicians, hospitals, and clinics to report to the Department of Health the full name, or initials, and address, sex, age, and occupation of every person infected with syphilis. Provision is made on the report form for the inclusion of information regarding the duration of the disease and the identity of the source of infection. U. S. Public Health Service penalty envelopes are provided for this purpose by the Bureau of Social Hygiene and require no postage.

Practical experience in New York City has shown that the application of direct epidemiological procedures to cases of early syphilis is the most effective means of discovering new foci of infection. Each infected person uncovered as a result of proper investigation and brought under treatment is a check on the further spread of the disease.

Each case of early syphilis is personally interviewed by an epidemiologist or the social worker, for the purpose of ascertaining primarily the identity of the person from whom he

may have contracted the disease, and the identity of individuals to whom he may have transmitted his infection. An attempt is first made to secure the examination of sexual partners, and the immediate family and household contacts, through the effort of the patient himself. More often, however, visits are made by the investigator to induce the suspected source and contacts to submit to examination and to treatment, if found infected. They are advised to go to a private physician or referred to a hospital or the nearest health department clinic, if unable to pay for private medical services. Household or family contacts are frequently examined at home, if they are unable to report to the clinic at stated hours.

If the patient fears to have the nature of his disease revealed to his family, he will usually coöperate in securing the examination of the family contacts on some pretext, such as life insurance purposes, or a periodic check-up of the general health.

If the person sought is not at home, a discreetly worded note in a plain sealed envelope, properly addressed, is left on the premises urging the respective individual to report to the office of the epidemiologist at specified hours for an interview. If there is no response to this request, a strongly worded special delivery or registered letter is sent.

Usually by persuasive means, it has been possible to gain the confidence and coöperation of all concerned and to induce the suspected source of infection and contacts to submit to examination and treatment, if needed. In every instance, the patient and his contacts are assured that their identities will not be revealed in the investigation, and that the information given by them will be held strictly confidential.

The same procedures apply to all cases of early or infectious syphilis in

the course of epidemiological investigation, whether referred by private physicians, health department clinics, non-departmental clinics and hospitals, or out-of-town official agencies. In the follow-up of patients referred by private physicians, workers invariably represent themselves as coming from the physician. One of the most important functions of the epidemiologists of the Bureau of Social Hygiene is to visit the physician in his office, to establish cordial relations, acquaint him with the program and services rendered him by the Department of Health, act in a consultative capacity, and, in general, advise and guide him on venereal disease problems. Frequently the epidemiologist will interview the patient in the physician's office, being introduced sometimes as a representative of the Department of Health, and more often as an interested professional colleague.

The staff engaged in these activities consists of 5 medical epidemiologists and 2 male investigators, under the supervision of an assistant director in charge of epidemiology, and 8 public health nurses, acting as nurse epidemiologists, 2 medical social workers, and 35 investigators and field workers, functioning under an assistant director in charge of nursing and social work.

Where infection of a person in New York City is stated to have occurred out-of-town, information regarding the suspected source of infection is reported to the health authorities of the city or town where infection is alleged to have taken place. In cases where it is believed that prostitution is carried on, such information is referred to the police authorities.

An important case finding procedure in New York City is carried on in relation to vagrants and sex offenders. All sex offenders, including those arrested on charges of prostitution, are required to be examined for venereal disease under the New York State

Public Health Law. This offers an excellent opportunity for the discovery of cases of syphilis. As one would expect, the incidence of syphilis in this group is very high.

During the year 1936, 3,804 women were examined in the health department diagnostic clinic at the House of Detention for Women. Twenty-two per cent were found to have syphilis, 23 per cent were found to have gonorrhea, and 13 per cent were found to have both syphilis and gonorrhea. Of the total number examined, 58 per cent were found to have one or both of these diseases.

In 1937, 4,254 women were examined in the health department clinic at the House of Detention—23 per cent were found to have syphilis, 35 per cent gonorrhea, and 10 per cent both syphilis and gonorrhea. Of the total number, 68 per cent were found to have one or both of these diseases. Under the Public Health Law cited above all persons arrested and arraigned on charges of vagrancy and prostitution are reported to the Department of Health and examined for evidence of venereal disease. Such persons may be detained until the results of these examinations are known. Persons with infectious syphilis are removed by the Department of Health to a quarantine hospital and held there until rendered non-infectious. In every instance the infected individual is interviewed by a nurse from the department for purposes of instruction and to secure information on sources of infection and contacts.

Two recently enacted laws in New York State are worthy of note in connection with the epidemiology of syphilis. The prenatal examination law provides that every physician attending a pregnant woman during gestation shall take or cause to be taken a specimen of her blood at the time of first examination, and submit it to an approved laboratory for a standard sero-

logical test for syphilis. The premarital examination law requires that prospective brides and bridegrooms must each obtain a medical certificate, based on a physical examination and a standard serological blood test, stating that they are free from syphilis, or, if infected, not in a stage which may become communicable, before they are granted a marriage license. The examination and blood test must be made within 20 days before receiving such license. The enactment of these two new progressive public health laws,

namely, the prenatal and pre-marital examination bills, will also serve as most effective case finding procedures. In New York City each year there are about 100,000 births and 70,000 marriages, which will result, therefore, in the annual serologic examination for syphilis of about 240,000 persons who otherwise might conceivably not be so examined.

No discussion of the epidemiology of syphilis would be complete in itself without a consideration of the facts recorded in the course of case investigation. Detailed record keeping is vitally important in the business of practical epidemiology. The form (Figure 1) has been drawn up in an attempt to indicate the course of procedure and essential data to be recorded for a complete epidemiological investigation of a case of early syphilis.

SPECIAL PROBLEMS

Certain difficulties are encountered in New York City in connection with the epidemiological investigation of syphilitic patients. One of the greatest problems is the lack of knowledge on the part of patients regarding the exact identity of the persons from whom they acquired the disease, as clandestine prostitutes and chance pick-ups. The patient may deliberately, or through no fault of his own, furnish the wrong information, resulting in failure to locate the named individual because of a fictitious address. There is, in addition, a large homeless and transient group in the city that is forever on the move; prostitutes will deliberately change quarters when they are being traced.

Some people who have changed residences are frequently located through the use of the mails, usually by a special delivery or a registered letter, marked "return receipt requested," and, in the case of families, through

schools, utility companies, or social and welfare agencies. A vast majority of the shifting population, however, leaves no forwarding addresses, either at old premises or with the local post office. As an example of this specific obstacle, of 566 individuals named as possible sources of infection during 1937 and the first three months of 1938, 212, or 37.5 per cent, were not located because of false addresses and frequent removals.

In some of the foreign quarters of the city, language difficulty presents another serious obstacle. While occasionally it is possible to have personnel familiar with the appropriate foreign tongue at certain clinics, this is not always possible.

PROGRESS IN THE FIELD

The following figures, covering the period of the entire year 1937 and the first half of 1938, indicate definite progress in New York City, despite the difficulties enumerated above.

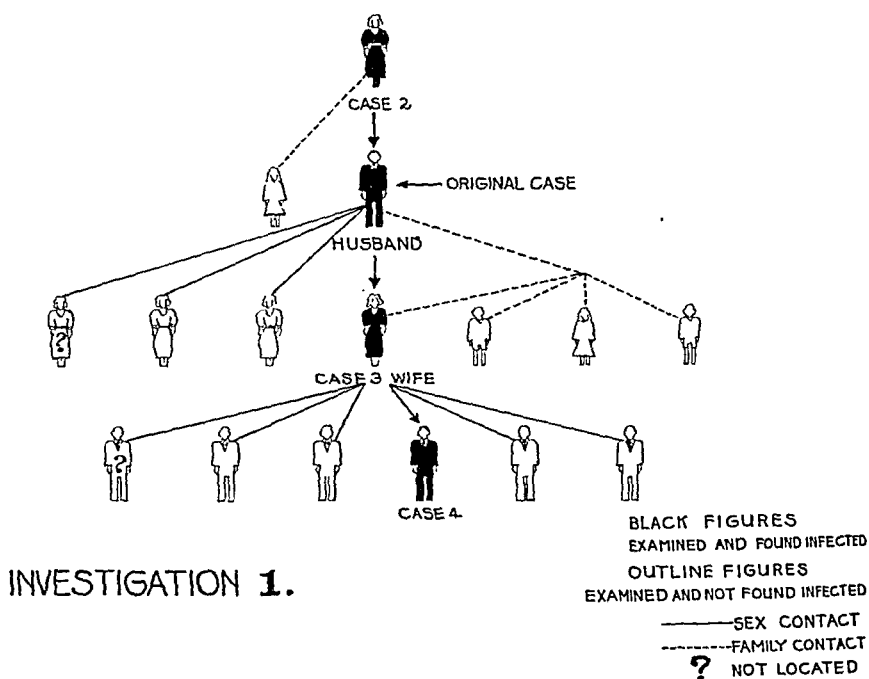

During the period under consideration, a total of 728 persons named as possible sources of infection of patients with early syphilis were investigated by the group of medical epidemiologists—394, or 54 per cent, were examined; 236, or 32 per cent, of those examined were found to be infected. Of 468 household and family contacts to patients with early syphilis named, 424, or 91 per cent, were examined, of whom 81, or 17 per cent, were found to be infected with syphilis.

The group of nurses and social workers followed 2,194 lapsed and delinquent patients, and succeeded in returning 61 per cent of this number to treatment. The home investigators made visits on a total of 25,552 patients and returned 58 per cent of these to treatment.

CASE REPORTS

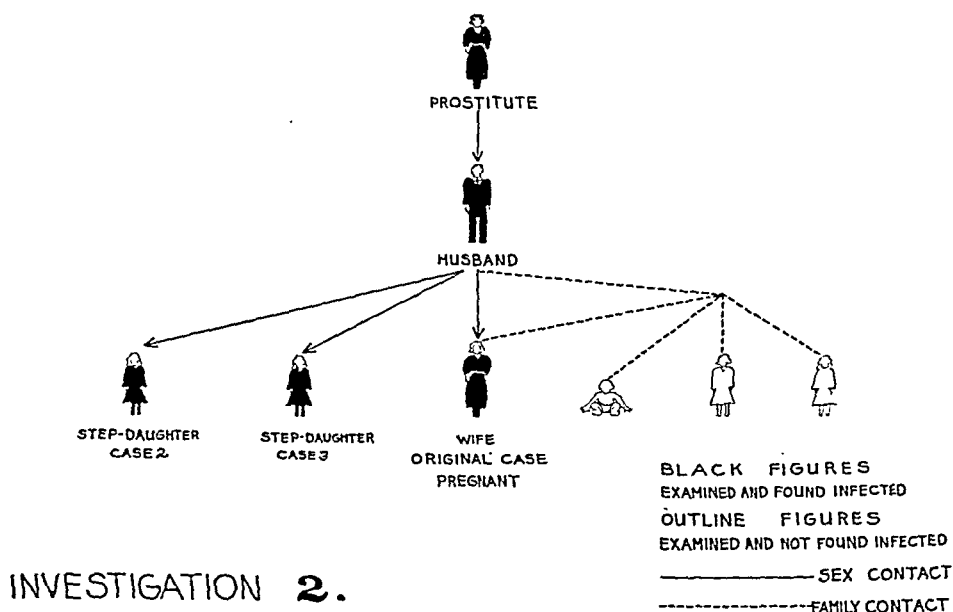

The practicability of epidemiological

LOCALIZED OUTBREAK OF SYPHILIS

CASE FINDING IN SYPHILIS

FOUR MEMBERS OF ONE FAMILY FOUND INFECTED

investigation of syphilis patients in New York City is illustrated by the following case reports:

Investigation 1—J. L., a white man, aged 48, was discovered to have primary syphilis on January 25, 1938. On investigation, it was believed that he had probably acquired his infection from Mrs. H. S., who was found to have early syphilis when she was brought in for examination. In addition to this woman, the patient admitted relations with three other persons, two of whom had no evidence of venereal disease; one could not be located because of false identification. On March 7, 1938, or about 2½ months later, the wife of J. L. developed secondary syphilis. She too proved to be promiscuous and admitted extra-marital sex relations with six men. Two of these were located and examined in New York, and showed no evidence of infection; one could not be found. The other men were examined by the health authorities in a neighboring state, with the result that one was discovered to have a strongly positive serological reaction and was placed under treatment, while the other two were found to be not infected. Four family contacts were examined and showed no signs of venereal disease.

Investigation 2—Mrs. I. S., a white pregnant woman in her 6th month of gestation was found to have secondary syphilis, and

gonorrhea, and was placed under medical treatment. At that time her husband refused to be examined, and her four children were found to be negative clinically and serologically. An apparently healthy looking normal baby was born January 2, 1938, with no signs of congenital syphilis or gonorrheal ophthalmia.

Two months later, two of her female children, aged 10 and 12 years respectively, were hospitalized, after being found with active secondary syphilis. The husband and stepfather was then induced to submit to examination and was found to have generalized adenopathy, a penile scar, and a strongly positive serological reaction. He admitted infection by a prostitute about a year previously. It is believed that he had infected his wife and also two of his step-daughters, while his wife was in the hospital for delivery. The four infected members of the family were placed under treatment at one of the health department clinics.

Investigation 3—A colored female, aged 27, was found to have secondary syphilis. She had probably acquired the disease from her husband, who was stated to have been in "ill health" and had left her several months previously, leaving no trace of his whereabouts.

She admitted sexual promiscuity with four men, two of whom were subsequently found to have primary syphilis with penile lesions

SOURCE AND CONTACT TRACING IN EARLY SYPHILIS

INVESTIGATION 4.

and positive darkfield findings, while one had no evidence of infection, and another one could not be located. The wife of one of the infected men, on repeated follow-up examinations, fortunately has been found free thus far from the signs of syphilis.

During the course of this investigation, another woman appeared at the clinic with a cutaneous syphilide and named the husband of the initial case as the source of her infection. Several attempts to locate this man, both in New York and in a neighboring state, were unsuccessful. All of the four infected individuals have submitted to prescribed courses of treatment.

Investigation 4—Several instances of transfusion syphilis recently occurred in New York City. One of these cases was reported by a private physician in a 9 year old female child. Investigation revealed that the child had had three blood transfusions because of a streptococcal infection following a mastoidectomy about 3 months previously. None of the donors had had his blood tested for syphilis prior to transfusion, in spite of the fact that the regulations of the Sanitary Code require this of all professional donors.

With the consent of the cooperating physician, six persons, including the blood donors and the immediate family, were thoroughly examined. The last donor was found to have a strongly positive Wassermann reaction, and was considered to be the source of infection.

The responsibility of preventing

transfusion syphilis is a weighty problem in itself, and rests with the physician making the transfusion. All authorities agree that in order to reduce the risk of infection in the recipient, a rapid and reliable serologic test, as well as careful physical examination, should be performed on every donor immediately prior to transfusion.

CONCLUSIONS

1. Investigation of patients with early syphilis has been found effective in New York City, despite the problems presented by fictitious address, constant migration, and language difficulties.

2. The search for sources of infection, and contact tracing is equally possible in private practice as well as in clinic and hospital practice.

3. Reduction in the syphilis rate will be accomplished by intelligent application of well established principles of practical epidemiology, together with the cooperation of the physician in practice. Emphasis is laid upon the personal interest and activity of the

individual investigator in contradistinction to such indirect methods of approach as the use of the mails, and messages transmitted by patients to contacts and suspected sources of infection.

OUR PUBLIC HEALTH SERVICE

ON the first day of July, 1939, the United States Public Health Service was officially removed from the Treasury Department, in which it was born and in which it has spent its entire life up to that date—nearly 141 years—to the Federal Security Agency, created under the "Reorganization Act of 1939," approved April 3, 1939, and which by joint resolution of the House and Senate became effective July 1, 1939.

The Service had its origin July 16, 1798, when President John Adams signed the Act of Congress which provided for hospitals for the medical care of American seamen. The first hospital for disabled seamen was established by Virginia at Washington, Norfolk County, Va., under a legislative act in 1782, and this hospital became the first actually provided under the Federal Act of 1798 establishing the Marine Hospital Service, having been purchased by the Government in 1801. However, the first treatment of seamen under that Act took place at Boston in 1799.

The public health functions of the Service grew slowly. It was not until 1878 that Congress authorized extensive use of the Service as a federal health organization. In 1890 it was authorized specifically to assist in preventing the introduction of cholera, yellow fever, smallpox, and plague. In 1893, the quarantine functions of the Service were extended to include all infectious and contagious diseases, in coöperation with state and local health agencies.

Other public health functions were added from time to time, and this expansion was recognized in 1902, when the name was changed to United States Public Health and Marine Hospital Service, under which it remained until 1912, when the title under which it is now known was given.

In 1901, the founding of the Hygienic Laboratory was authorized for investigation of contagious diseases and other matters pertaining to public health, and the next year, 1902, the Service was charged with the duty of supervising and regulating the manufacture and sale of sera, vaccines, and similar products shipped in interstate commerce. In 1912, the duties of research were greatly broadened,

taking in the investigation of all diseases of man and the conditions tending to influence their propagation and spread, including sanitation and sewage and the pollution of navigable streams and lakes. Our National Leprosarium at Carville, La., was established in 1917. During the same year the Service became responsible for the physical and mental examinations of all arriving aliens.

The Narcotics Division, renamed Division of Mental Hygiene, was created in 1929, with hospitals at Lexington, Ky., and Fort Worth, Tex., for the confinement and treatment of narcotic addicts, and in 1930 a hospital was established at Springfield, Mo., for defective delinquents.

An important advance came this year (1930) in the creation of the National Institute of Health, which succeeded the Hygienic Laboratory, with very broad duties and powers of investigation.

In 1918, Congress created the Division of Venereal Diseases, with power to coöperate with state departments of health for the control and prevention of these diseases. These activities have been greatly extended by an Act of 1938.

The Social Security Act, approved 1935, imposed on the Service the duty of assisting states and districts to establish adequate health organizations and to train personnel. The National Cancer Act, approved 1937, established the National Cancer Institute, with wide duties of investigation and research as well as treatment, and also the assisting of similar activities by other agencies, public and private.

This sketch will give some idea of the multifarious duties and responsibilities of our Public Health Service, which touch every part of our country and affect the welfare of every individual citizen. It goes without saying that much has been omitted. Nothing has been said, for example, of the emergency demands on the Service, such as the care of sick and disabled soldiers, sailors, and marines after the World War for three years, until the Veterans' Bureau was organized. The location of the Marine Hospital Service in the Treasury Department was logical at the time it was founded. The Treasury was the department concerned with commerce and the revenue cutters early took part in the enforcement of state quarantine laws. As the functions of the Service broadened and it was growing into a national health organization its position in the chief fiscal agency of the Government became more and more anomalous. Proposals to move it have been made frequently.

Many have felt that the importance of the health of the Nation entitled it to a seat in the Cabinet and not so long ago strenuous efforts, which looked as though they might be successful, were made to bring this about. Other plans have died a more or less lingering death and the Service has remained in the house in which it was born until now.

Under the Treasury the Service has fared well. Successive administrations, regardless of their political complexion, have realized the necessity of supporting health work liberally, and, what is equally important, of allowing the officers of the Service a free hand in the planning and execution of their duties. A few exceptions to this rule have occurred, but even when an active Christian Scientist was Director of the Budget, no important injury was inflicted.

The continuous growth of the Service and the position it now occupies show that it has been well taken care of, and further, that it has commended itself to the Nation through effective work.

In the Federal Security Agency are grouped a number of agencies having to do with the health and welfare of the people. The association with these should

be helpful and mutually beneficial. We have every reason to expect for our Public Health Service liberal support, and from it a continuation of the activities which have made it known as one of the strongest governmental health organizations in the world.

SHOULD PUBLIC HEALTH BE ADMINISTERED BY THE COURTS?

PUBLIC health officials who have been attempting to discharge their duties conscientiously and impartially are sometimes distressed to find themselves confronted with indictments or injunction proceedings. Defenses against these legal actions not only may raise unwarranted doubts as to the integrity or ability of the health officer, but they are time-consuming, may interfere with the proper conduct of official duties, and are often unnecessarily expensive.

Several such incidents have recently occurred. The health officer of a large eastern city was indicted for alleged criminal action in permitting a nuisance due to dumping operations supervised by another department of the city. The health officer of a large mid-western city was among the many defendants in an indictment for an alleged conspiracy to violate the federal anti-trust laws, as claimed by the government to apply to the distribution of market milk.

An indictment is, of course, merely a charge, which must be proved in court to be sustained. It does not necessarily mean guilt, and the defendant health officers in these cases were vindicated, temporarily at least, when the indictments were dismissed by the courts. Many persons believe, moreover, that both of these indictments were inspired by political rather than by strictly legal motives, although on that matter we express no opinion.

Public health administration is primarily the responsibility of the executive branch of the government, as represented in this instance by the health department. When legitimately conducted, such administration deserves a minimum of interference from the judiciary.

Under the American system of government, however, every individual is properly entitled to his day in court in order to secure justice and to right any legal wrongs actually done to him. While the courts always have been liberal in upholding as valid all lawful and reasonable actions of public health officials, they have been equally alert to restrain health officers whose procedures have been unreasonable, arbitrary, oppressive, capricious, or malicious.¹ For wrongful acts, beyond the scope of his authority, any health officer in this country or in Canada may be liable in a civil or even in a criminal action brought against him by an individual citizen or by the government.

The most competent health official is, generally speaking, one who can perform his duties with a minimum of litigation, either by or against him. There are, nevertheless, occasions when court action is necessary as a last resort. For such occasions, the sagacious health official will be amply prepared by his conduct and by his familiarity with legal principles applicable to public health, to prosecute or defend his cause with success and credit to himself and his community.

"IMPLEMENTING PUBLIC HEALTH"

ENGLAND, from which the awakening in public health matters came nearly 100 years ago, now announces another step forward in the appointment of a Committee on Research in Preventive Medicine.¹ With the announcement, however, there is a somewhat pessimistic note in certain journals. Twenty-five years ago in this country a noted student of public health said that if what we knew at that time could be translated into action, properly supported by laws and money, the death rate could be greatly reduced practically at once. Somewhat the same statement has been made over and over again with a great degree of truth. There is always a lag between discoveries in medicine and their practical application. The statement is made that in England in no field of medicine is this lag more evident than in public health. To a great extent this is true of America.

Immunization against diphtheria is given as an instance of one of the immediate problems which the committee has to consider. In spite of the proved efficacy of our preventive inoculations against diphtheria there is great difficulty in persuading the mass of people to have their children protected, and the rather astonishing statement is made for England that "the mortality-rate for diphtheria remains unaltered." Further, there is no town in England with an inoculation rate higher than 20 per cent and the protective injections are given chiefly between the ages of 5 and 10 years, while the greatest mortality in diphtheria is from 1 to 3. This pessimistic statement seems to contrast with the situation in America.

Each year there is a survey of the situation in regard to diphtheria which is published in the *J.A.M.A.* The cities of the country are divided into sections in which of course the incidence of diphtheria as well as the death rate varies somewhat. The latest report² covers 93 cities with an aggregate population of 38,885,435, in which there were 568 deaths, a rate of 1.46. Of these 93 cities, in 1935, 19 had a death rate of 5.0 or over. In 1936, 5 cities were in this class, and in 1937, only 3. In 20, the year passed without a single death from diphtheria. It is true that the actual number of deaths from diphtheria decreased only by 9, from 577 to 568, while the population increased from 36,777,112 to 38,169,704. These surveys began in 1923, in which year in an urban population of 31,060,848 the death rate per 100,000 was 13.13 against 1.46 in 1937 for 38,169,704 population.

The report says that there seems to be an increase in death rates which cannot be attributed wholly to the lack of intensive immunization programs, but it is concluded that there is evidence the extensive preventive program which has been carried on so widely throughout this country has resulted in a lowered death rate from diphtheria.

Our English friends suggest that the only proper way to test the efficiency of preventive inoculations is to select one city in which at least 90 per cent of its children on reaching the age of 12 months will be inoculated. This must be done with the collaboration of practising physicians and with the entire confidence of the medical profession and of the public. The suggestion is made that the new committee might very well attempt to discover an atmosphere in which such an experiment could be successfully put through in the ordinary routine of public health practice.

The make-up of the committee is interesting. It contains man with special knowledge in many branches of medical sciences, others whose lives have been

spent in public health administration. It includes members of the medical staff of the official health ministries of England and Scotland: The names of many of the committee are almost as well known in America as they are in England. The personnel assures us of a well considered and practical program which will be carried out with thoroughness. We can depend on findings through which England once again will demonstrate to the world her advanced conception of public health.

Tenth Annual Meeting of the Western Branch

THE Western Branch of the American Public Health Association held its 10th Annual Meeting July 23-28 in Oakland, Calif., under the presidency of Guy S. Millberry, D.D.S., of San Francisco. This first branch of the Association was organized in 1928 and affiliated with the parent association in 1930, with membership from 11 western states, 3 western provinces of the Dominion, as well as from Alaska, Hawaii, and the Philippine Islands. The meeting proved to be a notable occasion, not only because of an excellent program but in attendance as well. More than 700 persons registered for the meetings, or practically as many as attended the meeting of the A.P.H.A. in Pasadena 5 years ago. During the same week the Sixth Pacific Science Congress met in the Bay District, and there were more than 100 papers dealing with medical and public health subjects besides those regularly scheduled for the Western Branch.

The meetings of related groups were unusually fruitful and these included a dental congress, a conference of state supervising nurses, a round table of state and local registrars of vital statistics, meetings of the staff of the U. S.

Indian Service, of nutritionists, of state and local venereal disease directors, and a round table of state sanitary engineers.

Although several important reports were presented bearing on public health problems of particular interest to the western area, the most noteworthy event was without doubt the symposium on Health Education, under the chairmanship of Professor Ira V. Hiscock of Yale University. This symposium ran through 4 half-day sessions and included the participation of numerous specialized consultants. There were also round tables on the evaluation of administrative practices and on maternal and neonatal care. More than a decade of industrious work on the part of our western colleagues has resulted in a splendid organization whose fruits are readily apparent. The Branch installed Dr. Frederick D. Stricker of Oregon as President, and recognized the long service of Dr. William P. Shepard of San Francisco as Secretary by unanimously electing him President-elect. Dr. W. Ford Higby of San Francisco succeeds Dr. Shepard in the post as Secretary.

BOOKS AND REPORTS

Robert Koch: *Sa Vie et son Oeuvre*—By Dr. Emile Lagrange. Paris: M. Legrand (Boulevard St-Germain, 93), 1939. 90 pp. Price, \$.50.

The author deplores the fact that outside of Germany there is no adequate biography of Robert Koch, although everyone knows of the tubercle bacillus, the comma bacillus of cholera, and what is known as Koch's phenomenon. In English, except for the short article by Nuttall, one of a series on German bacteriologists, the only mention of Koch is in *Microbe Hunters*, by De Kruif, which he describes as a "clever but whimsical essay."

In a book on Koch's work one naturally turns to tuberculosis. From this we find an almost complete absence of knowledge of American work. The author speaks of Koch's blunder at the London Congress on Tuberculosis in 1901, mentions the disagreement with his stand by Lord Lister, Nocard, Bang, and McFadyean, but does not mention the American, the only person who gave facts to disprove Koch's statement; nor does he seem to have heard of the final proof given the next year (1902) of the communicability of the bovine tubercle bacillus to human beings. Again we must point out that this was American work done at the University of Pennsylvania. It has stood the test of time and has been corroborated in every country. There is no excuse for this omission by the author. He gives credit properly to Theobald Smith for having pointed out the differences between the human and the bovine bacillus before Koch, but his acquaintance with the American

literature concerning tuberculosis seems to end there. The author says 15 years before, but this is an error. (See *Trans. Assn. Amer. Physicians*, XI (1896) 75.) Elsewhere in speaking of the researches of Koch on malaria, he gives Theobald Smith credit for having been the first to have shown the transmission of disease by the bite of an insect, but he neglects to give equal credit to Kilborne, who did the work conjointly with Smith.

The author goes into the personal life of Koch and tells about his divorce and later marriage to an actress in Berlin. He also gives some incidents which are not generally known. For example, in speaking of anthrax, he says Koch tried to take credit away from Pasteur, although Pasteur had with absolute courtesy given full credit to Koch for what he had done. In spite of this, in Geneva, Pasteur was acclaimed as a second Jenner. He says that Koch was so jealous that the honors done Pasteur "prevented Koch from sleeping."

With the exception of more or less unimportant matters such as those mentioned, the book contains nothing new. The last two pages give an impartial comparison of Pasteur and Koch, especially in regard to what they accomplished. He places them along side of Ampere, Faraday, J.-B. Dumas, Darwin, Lister, Laennec, Bernard, and Virchow, and ends by saying that on account of their services to humanity they assuredly occupy the first place and due to their genius the sciences of hygiene and modern medicine were born.

For some years past the Europeans

have recognized American work. We cannot but think that the author of this work is very much behind the times and would profit by studying American literature. He signs himself as an inspector in hygiene in the Ministry of Public Health in Brussels. Entirely apart from the diseases, the elucidation of which brought such deserved fame to Koch and Pasteur, the author could learn a great deal from American literature concerning the general handling of all matters concerning hygiene and public health. Otherwise the book can be recommended for pleasant reading.

MAZÛCK P. RAVENEL

League of Nations—Survey of National Nutrition Policies, 1937–38—*New York: Columbia University Press, 1939. 120 pp. Price, \$.60.*

The Assembly of the League of Nations in 1937 began a movement which was designed to further the study of "the state of national nutrition and to improve nutritional standards," proposing at the same time that a meeting of the National Nutrition Committees be held annually.

Reports given to the Assembly by representatives of the National Nutrition Committees from 16 countries furnish the basis of the material incorporated in this book, in which a mass of facts of interest to the layman as well as to the nutrition specialist are presented in a summarized, easily readable form.

The survey includes: A report of the progress of the work of the League in regard to nutrition problems; a discussion of the type of work delegated to the National Nutrition Committees, the power of the committees, and sources of financial support for carrying out investigations; suitable methods for making nutrition surveys, in twenty countries, concerning the nutrition of the inhabitants; methods used in various countries to alleviate existing con-

ditions of under-nutrition; a discussion of economic situations in relation to nutrition; a report of special research problems on the vitamin and chemical composition of foods, and methods available for educating the public in regard to the underlying principles of proper nutrition.

All reports indicate (as is to be expected) that the plane of nutrition of the group is directly related to the level of the income. In addition such factors as: climatic and topographic conditions; types of soil, and amount per capita accessible for the production of food materials; transportation, care in handling and methods of preserving food; an understanding of the principles of nutrition and a knowledge of wise spending of the income, all have an important bearing on the problem of proper human nutrition.

ADELIA WEIS

A Synopsis of Hygiene—*By Sir W. Wilson Jameson, M.D., and G. S. Parkinson, with a Section on Personal Hygiene by G. P. Crowden (6th ed.). London: J. & A. Churchill, Ltd., 1939. 687 pp. Price, \$6.25.*

From the first edition of this book which appeared in 1920 until the sixth in 1939, it has always been of the highest quality and practically beyond criticism as judged by the claims of the authors. We learn from the Preface to this edition that the sections dealing with occupation and health, hospitals, maternal welfare, and milk have been completely recast, and that the law relating to food and drugs and to factories has been restated owing to recent legislation. The book is largely a synopsis of current public health administrative practice based on official reports and memoranda which are cited in the text, generally with the date. There are, however, further references to original sources which one may consult.

The book has been brought up to date, as shown by the inclusion of material concerning the legislation as to Public Health (Aircraft) Regulations, 1938.

The one criticism which might be made is the small amount of space given to insects which carry disease, a trifle over 7 pages, with only one illustration. One could wish also, though this is not a criticism, that the authors could have given us more of their own ideas and not stuck quite so closely to their expressed purpose to "present so far as possible only official or generally accepted views."

One cannot study a book of this sort without learning a great deal and acquiring admiration for the careful and methodical way in which the material is presented. It is more a book for public health workers and students than medical students. Its usefulness for this country is somewhat limited by the fact that all of the current references are to British laws, regulations, reports, etc. We could wish that someone would do for America and American laws regarding public health what the authors have done for England. All through, abbreviations, of which the English are very fond but which are not understood in this country, are used, though a list of them is given at the beginning of the book.

It is hard to speak too highly of this work, in spite of the drawbacks mentioned as far as use in America goes. The printing and make-up are excellent and there is a good index. Only 16 illustrations are given.

MAZŮCK P. RAVENEL

Taking Care of the Family's Health: A Teaching Guide for Rural Classes—*By Elma Rood and Gertrude Lingham. Madison College, Tenn.: Rural Press, 1938. 3 parts in 2 books. 597 pp. Price, \$5.00; flexible fabrikoid, \$6.50.*

These two volumes may be classed as a manual designed to give practical teaching help to persons in the public health field. Sixteen instructional units are organized under three headings: (1) The Family in Health, (2) The Family in Illness, and (3) The Family and Public Health.

Many practical ideas adapted to rural conditions are given, but one wonders if suggestions for several types of approaches dependent on needs and interests might be more helpful than considerable detail on teaching technics. Values of several good illustrations would have been increased by the use of descriptive titles. However, the activities proposed are excellent and the subjects of the units are well chosen, being topics especially appropriate for rural groups. Procedures are suggested for class periods and opportunity is given for the imaginative nurse or teacher to use her own initiative in the adaptation of material. The price of these volumes may limit their use.

IRA V. HISCOCK

Hereditary and Environmental Factors in the Causation of Manic-Depressive Psychoses and Dementia Praecox—*By Horatio M. Pollock, Benjamin Malzberg, and Raymond G. Fuller. Utica, N. Y.: State Hospitals Press, 1939. 473 pp. Price, \$2.50.*

The importance of research into the etiological factors of mental disease is yearly receiving greater recognition. This volume, dealing with hereditary and environmental factors in two of the most important groups of the functional psychoses is one of the series of research studies undertaken jointly in 1928 by the New York State Department of Mental Hygiene and the State Charities Aid Association, with the financial assistance of the Laura Spelman Rockefeller Memorial.

The method employed in this study was to examine in detail the family and

environmental history of two groups of patients with mental disease. One group consisted of 155 first admissions with manic-depressive psychoses, and the other of 175 first admissions with dementia praecox. A study of the family histories of these two groups showed that in both cases there was more mental disease in these families than is to be expected in a corresponding random sample of the general population. However, in neither case was it possible to show that Mendelism explained the transmission of manic-depressive psychosis or dementia praecox.

The authors draw the conclusion that "It (mental disease) requires something in addition to a diathesis or predisposition. There must not only be a seed but a ground in which to plant the seed. Inferior human stock may still be enabled, through proper nurture, to achieve a life of a fair degree of usefulness. On the other hand, we know that even the soundest of stock may succumb to the repeated onslaught of an unfavorable environment."

Although the study only confirms the views generally held rather than shedding new light in the approach to the problem of preventing the occurrence of mental disease, the authors are to be congratulated on their work in applying statistical methods to such a difficult field in a manner that allows for definite conclusions.

The book is readable, is well printed, and should receive a warm reception from all interested in the progress of mental hygiene from its present status to one in which prevention of mental disease will take its proper place.

GRANT FLEMING

ical Research Council, Industrial Health Research Board Report No. 80. New York: Chemical Publishing Co. of New York, Inc., 1938 (1st American ed., by permission of His Majesty's Stationery Office, London). 388 pp. Price, \$3.50.

This is a very valuable book, thorough, careful, up-to-date, and readable. The claim that it consists of summaries of published articles, is far too modest, as it is a critical evaluation of those articles. When an author fails to present sufficient data to support his theses, when conclusions are drawn but the bases therefor are not given, that fact is stated. The critical attitude is maintained throughout, although expressed with due brevity. For instance, the views of Duvoir and of Flury and Zernik concerning chronic intoxication in man through petroleum spirits are given, but with the comment that no authority for the statements appears and even the exact variety of petroleum distillate is not given. The articles reviewed cover the period up to December, 1935, with a few of later date. The chapters on coal tar distillates and on the chloro compounds were of special interest to the reviewer and in her treatment of controversial features in those fields the compiler displays a very intelligent neutrality. The contents include (I) The Hydrocarbons, (II) The Chloro Compounds, (III) The Alcohols, (IV) The Esters, (V) The Cyclohexane Derivatives, (VI) The Ketones, (VII) The Glycol Group, (VIII) Miscellaneous: Carbon Disulfide. Ethyl Ether. Iso-Propyl Ether. Pyridin.

A full bibliography is given at the end of each chapter and there is a very satisfactory index.

ALICE HAMILTON

Toxicity of Industrial Solvents: Summaries of Published Work—Compiled by Ethel Browning under the direction of the Committee on the Toxicity of Industrial Solvents. Med-

Alcohol: One Man's Meat—By Edward A. Strecker and Francis T. Chambers. New York: Macmillan, 1938. 230 pp. Price, \$2.50.

Alcoholism and mental disease are age-old twins. Together they present a problem that has baffled social and medical efforts from time immemorial. But science, taking up the challenge, is throwing new light on some of its physical and mental aspects. It has, for example, demonstrated that alcohol is a narcotic drug, not a stimulant, and it has shown the relationship between alcoholism and vitamin B₁ and C deficiency on the one hand, and injury to the nervous system on the other, a relationship of far-reaching social and psychiatric importance. And this advancing knowledge offers a basis for the rising hope that the drinking problem, in some of its forms at least, will progressively yield to therapy and prevention.

The book under review is an unusually valuable contribution toward a better understanding, by the layman and student, of the fundamentals of a social evil that has been the despair of reformers for centuries. It lights up the psychological, physiological, and social factors that are at the basis of the drinking habit and clarifies the problem considerably; and by its reporting of the impressive results secured by the authors in their treatment of certain types of alcoholics, through "an intensive psychological reëducational approach," shows the possibilities of dealing constructively with the problem.

The authors differentiate between the "normal" and the "abnormal" drinker, and describe drinkers who have a "psychic allergy" to alcohol, in contrast to those who "can take it." Allergic individuals, they say, simply and sensibly, "should never drink alcohol, for even when they take it in relatively small quantities they are not normal drinkers." One man's meat is, indeed, another man's poison. The abnormal drinker, on the other hand, whether allergic or not, is the man who cannot face reality without alcohol, but

"whose adequate adjustment to reality is impossible as long as he uses alcohol." These are the excessive drinkers, to whom alcohol is a mechanism of escape, a release from inhibitions, the magic that brings euphoria and anesthesia. Here the impulse to intoxication is rooted in the conflict between instinct and ideal, and alcohol is the great solvent, the treacherous boon to man's ego.

In this interesting and highly readable treatise we are given an instructive, scientific, and practically useful interpretation and evaluation of the why's and wherefore's of drinking and of the psychiatric approach to its management and control. Of special value is its hopefulness of outlook which should do much to encourage the provision of institutional and clinical facilities, now all too meager, for the special study and treatment of alcoholic addiction. Best of all is the sound philosophy of the book which points the sober attitude, the middle road we should take between the extremes represented by prohibition on the one hand and the night-club era on the other. Education for temperance is the ultimate, rational answer.

PAUL O. KOMORA

The Microbe Man: A Life of Pasteur for Young People—By Eleanor Doorly. New York: Appleton-Century, 1939. 160 pp. Price, \$1.50.

Of the many ardent Pasteurians, quite a number shared their enthusiasm by writing books about Pasteur. These books differ more in style and garb than they do in subject matter for the standard work of Rene Vallery-Radot, *La Vie de Pasteur*, is available to all with itching pens.

The author's approach is that of an imaginative tourist. She visited the many places made famous by this great man, all faithfully. Thereafter she returned to her home in England, where she is a school teacher who graduated

into head mistress, and wrote another book about Pasteur.

Her presentation is for young readers. Herself a teacher, Miss Doorly's book has a smooth flow presenting the essential facts of Pasteur's life within reach of a child's vocabulary and interest.

The book is embellished by an introduction by Professor Pasteur Vallery-Radot.

W. W. PETER

The Canned Food Reference Manual—*New York: American Can Company, 1939. 242 pp. From the Company.*

This booklet is a striking example of enlightened advertising. When we consider the enormous part which the art of canning plays in the preservation of food and in our everyday life it is of great importance that the public should have correct information concerning the processes involved as well as the general effect on the foods preserved in this manner.

This book is the third of the series issued by the American Can Company and has been prepared to amplify and extend rather than to replace the publications which have preceded it. After a short history of canning there are accounts of the processes involved in canning, beginning with the manufacture of tin plate, fabrication of cans, and going through to the selection of foods and the basic operations through which they are put, ending with the heating and subsequent cooling.

The next section treats of canned foods in human nutrition in which are given the nutritive requirements of the body, the story of the vitamins, their standards, units, and stability. The public health aspects of canned foods are discussed, and an account given of 20 years of research concerning canning. One section is largely practical and gives the government regulations concerning processed or packaged foods,

their specifications and grades, while the last section gives the Federal Food, Drug, and Cosmetic Act.

There is an Appendix carrying 23 items, all of them practical and useful in everyday life, not only to the housekeeper but also to the physician and the nutrition expert. A good index ends the book. The work is thoroughly documented and the material has been submitted to the Council on Foods of the A.M.A. for review and acceptance before publication. The illustrations are abundant and excellent.

MAZÛCK P. RAVENEL

Immunity Principles and Application in Medicine and Public Health—*By Hans Zinsser, John F. Enders, and LeRoy D. Fothergill (5th ed. of "Resistance to Infectious Diseases"). New York: Macmillan, 1939. 782 pp. Price, \$6.50.*

The material is divided into two sections, one devoted to principles and theory and the second to special immunological problems in individual infections.

Four chapters give critical discussions of infection, virulence, antigens, toxins, and immunity, six chapters deal with the nature of antibodies and various antigen-antibody reactions such as toxin-antitoxin, bactericidal, agglutination, precipitation, iso-antibodies and blood groups. Five chapters are devoted to hypersensitiveness. Section II deals with immunity to virus and allied diseases, immunity in syphilis, tuberculosis, diphtheria, tetanus, and other anaerobic infections, scarlet fever and other streptococcal infections, staphylococcal infections, meningitis, pneumonia, the enteric infections, and whooping cough. Three chapters are devoted to applied immunology in bacterial and virus diseases, and in snake-bite poisoning.

The authors say they have "attempted to retain much of the character

of the previous editions and to meet the need for increased correlation between the principles revealed in laboratories and their applications to the problems of the clinic and of public health." They are to be congratulated on the success they have achieved in attaining their goals. The arrangement of subject matter has been distinctly improved.

There are a few places where some ambiguity may exist relative to a few fundamental concepts. This is illustrated by the attempt, on page 374, to modernize the old definition of an antigen by saying "a rational comprehension of immunological processes necessitates an inclusion in the biological conception of antigenic substances *all materials* which, in contact with the animal body, lead to a specifically altered reaction capacity." That the authors do not regard formaldehyde, iodine, etc., as true or complete antigens is indicated by earlier discussions and on pages 376 and 377. Likewise the statement (pages 445 and 446) that "there is evidence to indicate that there is *no* stable union between virus and antibody, etc." and that "Enders and Shaffer have carried out experiments with pneumococcus and pneumococcus antibodies which both in principle and results, are entirely analogous to the virus-antibody 'dilution' phenomena of Schultz and Andrews." It is doubtful whether the authors wish to claim that in general bacterial antibody does not form a fairly firm union with its antigen or that complete dissociation of any bacterial antibody from its homologous antigen can be readily obtained by dilution as might be inferred from these and a few succeeding paragraphs.

On scarlet fever the reviewer is left with the impression that while the authors are apparently in agreement that the erythrogenic toxins are responsible for the rash and certain other

phenomena yet perhaps in spite of the apparent positive stand taken, they are either in doubt or in disagreement as to whether the etiology is settled in its entirety.

Some apparent inaccuracies or inadequacies in references to the literature occur. On page 340 a translation of Morgenroth's "Collected Studies in Immunity" is quoted to the effect that Magendie's early experiments on anaphylaxis were done on dogs. Richet in his treatise on anaphylaxis and also Doerr in Kraus and Levaditi's Handbuch (p. 858, Band 2, 1909) quote Otto's review of Morgenroth as saying that Magendie used rabbits. The authors (page 353) describe Manwaring's perfusion experiments on dogs and cite his conclusions but omit later work by others which puts a different interpretation upon his results. On page 360 it is stated that Schultz in 1910 showed that smooth muscle from sensitized animals would "react, by contraction, to amounts so small that they had practically no effect upon the normal tissue." Schultz's early experiments were very crude and it was Dale who refined the technic and called attention to the importance of distinguishing toxic from non-toxic doses of antigen in smooth muscle experiments. The citation of Wells (page 363) while correct in so far as it goes is misleading in that it might easily be interpreted as representing Wells's objections to the histamine theory. If ten more lines from Wells's book had been included they would have portrayed accurately his views.

While the book, because of the regrettably short time allotted to immunity in the medical curriculum, is too large to be used as a didactic text and lacks many valuable references it is nevertheless a splendid example of what it is intended to be—a critical treatise expanded to include chapters that correlate the principles revealed in the

laboratories and their application to the problems of the clinic and of public health.

The subject matter is well arranged and does not contain a noteworthy number of typographical errors. While the index is fairly good, it is hardly adequate considering the large amount of material presented. The publishers are to be congratulated upon their achievement.

N. P. SHERWOOD

The Span of Life—By William Marias Malisoff. Philadelphia: Lippincott, 1937. 339 pp. Price, \$2.50.

The author is a research chemist, inventor, professor in the Graduate School in the University of Pennsylvania, and editor of *Philosophy of Science*. He is eminently qualified to bring together a great variety of interesting things on the subject of the span of life.

Life at its oldest includes the big 12,000 year old macrozamia tree in Queensland and small organisms revived by surviving Russian scientists after these biological specimens spent from one to 3,000 years in arctic ice. It is easier to determine the approximate age of some of these ancient forms of life than for the human beings who have crept into legends of longevity: Adam, 930 years; Seth, 912; Enos, 905; and Methuselah, 969; or to prove that Methuselah begat children at 187, and Noah at 500. It is a lopsided list of humans for, strangely, no woman is included among the long-livers.

The author reviews a wide assortment of theories as to what determines longevity, ranging from popular hokuspokus involving palm readers and astrologers to the more elaborate theories constituting the pitfalls of scientists. Systolic blood pressure, weight, aortic and radial pulse, calcium content of the blood, gastric acidity, anatomic changes in the knee joints,

structural transformation of the thyroid, are some of these.

Use has been made of laboratory animals in ingenious experiments. Rats and rabbits lost an assortment of their internal organs, had to eat a variety of foods or starve, were controlled in their mating, and the number of days added to or subtracted from their average span of life were determined.

The author quotes definitions of life in terms of chemistry, physics, electricity, and architecture of the atom as advanced by many philosophers and scientists, among them Bichat, who said: "Life consists in the sum of the functions by which death is resisted."

"Apparently the definition and treatment of life varies with the level of discussion the definer has in mind. He may be thinking of the physical level, the biological level, the psychological level, perhaps even the theological level; as he 'raises' the level he is likely to deny that the discussion at other levels is about life altogether." But "all the molds crack; they are too narrow, above all too rigid, for what we try to put into them." About almost every definition one can say, "Yes and more."

Finally the author moves toward one reasonable proposal for belief and action in the form of this thesis, "The hope of prolonging life indefinitely is the proper thing for science. All research should be organized with that as the supreme goal." W. W. PETER

Man Against Himself—By Karl A. Menninger. New York: Harcourt, Brace, 1938. 485 pp. Price, \$3.75.

The ingenuity and fertility of the Freudian theories in explaining some of the mysteries of human behavior are beautifully exemplified in this second major work of Dr. Karl Menninger, probably the most successful public interpreter of psychoanalysis among its practitioners in this country. The brilliant and dynamic author of *The*

Human Mind, best seller among the many lay treatises on the new psychologies that have appeared during the past decade, again shows his gift for popular exposition, this time in an attempt to elucidate some of the occult psychological mechanisms involved in the "manner of man that kills," in his aggressions toward himself and others. And the upshot of his elaborate thesis, based on Freud's concept of the death instinct, juxtaposed against the instinct of self-preservation, is that man is his own worst enemy, as the title of the book implies.

How the conflict between the destructive and constructive impulses in man takes place, the complexities and ramifications of this morbid phenomenon in human nature, the diversity of its manifestations, and the significance of its outcome for the present and future welfare of the race—such is the subject matter of this analytic and, in a way, novel and daring study of the riddle that is man.

Taking as his point of departure and frame of reference the age-old problem of suicide, which he analyzes in characteristic Freudian fashion, Dr. Menninger builds up a complicated conceptual structure in which he sees asceticism and martyrdom, neurotic invalidism, alcoholic addiction, anti-social behavior and mental disease as so many forms of "chronic," progressive suicide, and this not in a merely analagous sense—in which, for example, we say that people, through dietary indiscretions, "dig their graves with their teeth"—but as the actual result of unconscious motivations based on the self-destructive impulse. Even the aggressions of the habitual criminal "lead

to self-destruction in the sense of imprisonment, misery and deprivation."

So pervasive and insidious is the "death instinct" that, in the development of his thesis, the author includes self-mutilation, malingering, polysurgery, purposive accidents, impotence and frigidity—classifying these under the heading of "focal" or localized suicide—and a whole range of physical diseases and disorders—denominating these as "organic" suicide. In the process he dissects, with his analytic knife, many an established ethical, moral and religious concept, showing, as he claims, the psychopathology underlying much in human behavior that masquerades as virtue. The book is replete with interestingly presented and well documented case material illustrating the far reach of his concepts.

How and when the aggressive impulses are thwarted in their overt projections and are turned inward, thus leading to self-destruction, is an obscure and highly complex psychological process that requires studious effort if the reader is to grasp the closely reasoned arguments the author employs so engagingly and with such *gusto* in defending his thesis. These extensions of the psychoanalytic theory of self-destruction to a variety of problems in human morbidity are not offered as scientifically proven demonstrations, but are rather a compound of clinical observation and philosophic speculation based on Freudian concepts and, in their deductions, highly plausible and tenable, if we accept the basic premise. It is an interesting hypothesis that stands or falls with the body of psychoanalytic doctrine.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Health in All New York—Here you will find a stimulating example of descriptive reporting. The true journalist selects some rather bizarre activities from among the wealth of more sober material that so large an organization as the combined New York City health agencies furnishes. The professional health publicist probably would choose otherwise, but we question whether he would be more successful in packing a revealing story in a very small space. One choice sentence: "Public health is separated by a line as theoretical as the Tropic of Capricorn into preventive and curative medicine."

ANON. Health and Hospitals. Fortune 20, 1: 97 (July), 1939.

Our Unenviable Smallpox Record—About 15,000 reported cases of smallpox during 1938 constitute an eloquent testimonial to our collective common sense. New Jersey has not had a case in 7 years. Seven western states with a smaller combined population have had 12,000 cases in the same time. We have not had outbreaks of the virulent type since the middle 20's, but when we do the fat will be in the fire.

ANON. Why Smallpox? Pub. Health Rep. 54, 25: 1091 (June 23), 1939.

Some Health Profits—Of the young men recently called to the British Army only 2.3 per cent were found unfit for military duty. If, as the minister of health suggests, this vastly better showing is the result of the improved health services, there is reason to hope that another generation will be in even better shape, for in 1918 and 1919 when the present crop of recruits were born,

infant hygiene and school health services were still in a nebulous state, and the drive for decent housing was a long way from beginning.

ANON. Editorial Notes. J. Roy. San. Inst. 2, 7: 397 (July), 1939.

Canadian Certification of Sanitarians—In Canada, the Public Health Association grants the degree C.S.I. to persons who pass qualifying examinations and present evidence of stipulated standards of training and experience. It is hoped that eventually only C.S.I.'s will be employed by municipal health departments. Is there a hint here for us?

ANON. Report of the Committee on the Certification of Sanitary Inspectors. Canad. Pub. Health J. 30, 6: 309 (June), 1939.

Praise for the Public Health Nurse—Emphasis upon the necessity for a working partnership between nurses and other professional groups in the public health program, marks this plea for more and better public health nursing.

ATWATER, R. M. The Place of the Public Health Nurse in a Community Program. Canad. Pub. Health J. 30, 6: 278 (June), 1939.

Life Expectancy and You—Useful for many purposes is this table of expectation of life comparing rates now and at the time of other "World's Fairs." Not only is the longevity outlook better at birth, but so is the expectancy at older ages. It is only human for any health official to take both interest and pride in this accomplishment.

DUBLIN, L. I. Increasing Life Expectancy. Neighborhood Health (New York City Dept. of Health) 5, 4: 8 (July), 1939.

Quality of Material in Infant Manufacture—Neonatal mortality and stillbirth rates among babies born to mothers who had previously had infant losses were significantly greater than the rates among children of mothers who had not suffered such misfortune. The implications of these findings to agencies giving prenatal care with limited nursing staffs should be evident. There are other social agencies, too, that may well give heed to this phenomenon.

GARDINER, E. M., and YERUSHALMY, J. Familial Susceptibility to Stillbirths and Neonatal Deaths. *Am. J. Hyg.* 30, 1: 11 (July), 1939.

Is Rheumatism Handed Down?—Evidence is presented which suggests that a hereditary constitution may play a rôle in the predisposition to rheumatic disease, but it cannot exclude the possibility that exposure and infection may be the predominating factors.

GAULD, R. L., *et al.* Further Observations on the Occurrence of Rheumatic Manifestations in the Families of Rheumatic Patients. *Milbank Quart.* 17, 3: 263 (July), 1939.

One Hundred and Forty-one Years—In this brief history of the Public Health Service you will find some information that you already have and much that you should. As the service passes from the Treasury Department the occasion is used to review the steps by which it grew to its present place of influence.

HAMPTON, B. C. The Public Health Service Leaves the Treasury Department. *Pub. Health Rep.* 54, 26: 1133 (June 30), 1939.

Thought-Control Clinic—Health officials will be impressed with the group method of treating emotional disorders which has proved its worth in one city dispensary. Individual psychotherapy for the horde of neurotics who need public assistance is entirely beyond the

means of any health agency. This is a way out of the dilemma.

HARRIS, H. I. Efficient Psychotherapy for the Large Outpatient Clinic. *New Eng. J. Med.* 221, 1: 1 (July 6), 1939.

Health Problems in Education—Tentatively proposed, a statement of health policies for school adoption is discussed briefly by a school physician, a physical educator, a practising physician and administrator. This and the accompanying article deserve serious reading. The schools' responsibilities include a healthful environment, care of accidents, control of communicable diseases, teaching health habits, repeated physical examinations, and training of teachers.

HUMPHREY, J. H., *et al.* School Health Problems. *J. A. M. A.* 113, 1: 63 (June 1), 1939.

Perish the Thought Department—How public health administration works in England is told by the head worker. On paper, the British unified scheme of things sanitary certainly reads better than would a comparable report upon the jumble of agencies and activities hereabouts. That it could possibly be better, no red-blooded, two-fisted, he-American would for a moment admit.

MACNALT, A. The Health Services of England and Wales. *Canad. Pub. H. J.* 30, 6: 269 (June), 1939.

Deficiency Diseases and War—Aside from whatever military value it may possess, this paper on the behavior of Republican Spaniards will prove immensely interesting to sanitarians. During the 30 months of air raids, about the same number of Barcelonians were killed by bombs as in street accidents during the same time. It wasn't TNT, but lack of butter, that broke morale. Children were less worried than adults about danger.

MIRA, L. Psychiatric Experience in the Spanish War. *Brit. M. J.* No. 4093, 1217 (June 17), 1939.

American Legion Child Health Program—"In concluding," concludes this author, "I would like to summon . . . all of those groups definitely interested in the improvement of child health and child life to combine so that their combined influences may eliminate from our American Life disease, ignorance, poverty, propaganda, and politics." That, in a word, is some job.

MITCHELL, E. C. Child Health in National Defense. J. A. M. A. 113, 1: 1 (July), 1939.

Natural Vitamins or Fortified Foods—This symposium or fortification of foods, is an absolute "must" for every reading list. Some of the highlights: "whole fresh foods properly selected can support abundant health without addition or sophistication. But . . . urban populations must subsist on foods that are neither whole nor fresh . . ." From another paper: ". . . diets of our people at their best have no great margin of safety, and a significantly large proportion of them . . . are deficient in one or more of the dietary essentials." And this from still another: ". . . we are justified in locating our public health problems in the prevention of dietary deficiency disease in that section of the population with the lowest income. . . . Actually, we are making it more difficult for them to obtain these foods for . . . the addition of vitamins to food will increase the cost." And there is a lot more.

MORGAN, A. F., *et al.* The Fortification of Foods with Vitamins and Minerals. Milbank Quart. 17, 3: 221 (July), 1939.

What You Should Know about

Tuberculosis—If you will not read the whole article, you simply must read the sections headed "Well Established Facts," and "The Future." No matter what your job may be, you should know that: treatment has no influence on primary tuberculosis; children's preventoria are not justified; routine X-raying children's chests is no longer profitable; more first infection occurs in adults than in children. There is a lot more that you should know.

MYERS, A. J. The Physician and Tuberculosis. J. A. M. A. 113, 3: 189 (July 15), 1939.

Health State of the Nation—Briefly surveying recent progress made in the several fields of the national health program through joint federal and state action, the Surgeon General welcomes the annual conference of state health officials. In the succeeding paper the principal actions of the conference are summarized.

PARRAN, T. State and Territorial Health Officers Annual Conference with the U. S. Public Health Service. Health Officer 4, 2: 56 (June), 1939.

O.T. vs. P.P.D.—Purified Protein Derivative, in the studies reported, gave evidence of greater specificity than Old Tuberculin. Health workers in the tuberculosis control field will find much of value in related findings of the study, but the above nubbin will be about enough for the rest of us to store away in the back of our several noodles.

SEIDEMAN, R. M. A Comparative Study of Old Tuberculin and the Purified Protein Derivative. Am. J. Hyg. 30, 1: 1 (July), 1939.

OAKLAND CIVIC CENTER AREA
 INCLUDING
 THE UNIVERSITY OF PITTSBURGH

Pittsburgh's Entertainment Plans

DELEGATES to the A.P.H.A. convention in Pittsburgh who arrive early will be welcomed Sunday and Monday, October 15 and 16, by the Reception Committee and the Women's Entertainment Committee. Members of both of these groups will be available all week to give their services in helping to plan enjoyable days for the visitors, to suggest diversions and shopping tours, and to arrange for golf at Pittsburgh's private clubs.

The President's Reception will be held on Tuesday evening, and dancing will be in order immediately following the Reception.

Wednesday evening will be devoted to the dinners of the various sections. Among them will be an informal dinner held jointly by the Tri-State Food Association and the Pennsylvania Public Health Association. After the dinner the groups will join in a public meeting

at which the speakers will be Arthur T. McCormick of Louisville, Ky., and Henry F. Vaughn of Detroit, Mich. The Industrial Hygiene Section is planning an elaborate program for the same evening in celebration of its twenty-fifth anniversary.

A sight-seeing trip is planned for Thursday afternoon. Visitors will be taken in buses across the Allegheny River to the North Side and then along a route which views the Home of the 57 Varieties, the new Allegheny General Hospital, the Buhl Planetarium, and the famous old Allegheny Market, now the North Side Market. The buses will then proceed to the Point Bridge and cross over the junction of the Allegheny and Monongahela Rivers to the South Side. There ascent will be made by incline to Mt. Washington for a view of Pittsburgh's Golden Triangle. The trip will continue to the Oakland

Courtesy of U. S. Army Engineers, Pittsburgh

Elmsworth, one of Pittsburgh's 25 locks and dams on the Ohio River

District for visits to the Cathedral of Learning, Foster Memorial Hall, Heinz Memorial Chapel, the Medical Center of the University of Pittsburgh, Mellon Institute, and the Carnegie Library and Art Institute where the International

Art Exhibit will be open. Finally the party will go to the Hotel Schenley for tea. Later the guests will be returned to the downtown district.

Thursday evening the Banquet of the Association will be held in the Chatter-

New Lights were added to the Pittsburgh industrial night scene when Jones & Laughlin Steel Corporation opened its new \$25,000,000, 96 inch continuous strip mill. Extending for more than a half mile along the Monongahela River within sight of Pittsburgh's Golden Triangle, this mill was the first for the manufacture of wide sheets and strip in the Pittsburgh District. The glare in the background is from Bessemer Converters on the other side of the river.

Allegheny General Hospital

box of the William Penn Hotel. After-dinner speeches will be limited both in length and number so that time may be preserved for the entertainment to follow. It is hoped that the guests at the Banquet will be given something of a surprise in the way of entertain-

ment. The Medical Gridiron Club has been responsible for many good-natured ribs in the past. It is rumored that they are to be augmented by some experienced artists who will attempt to cast the light of travesty upon some of the pet foibles of the A.P.H.A.

George Westinghouse Bridge, Lincoln Highway, East Pittsburgh

TRIPS

The following schedule has been arranged by the Committee on Scientific Trips. For detailed descriptions of these tours, see the August issue of this *Journal*.

Tuesday morning:

A visit to the City Filtration Plant at Aspinwall

Tuesday afternoon:

A visit to the U. S. Bureau of Mines and an alternate trip to the Cooking Utensil Division of the Aluminum Co. of America

Wednesday morning:

A visit to the Mine Safety Appliances Company

Wednesday afternoon:

Trips to the H. J. Heinz plant and the Jones and Laughlin Steel Company

Thursday morning:

A trip to the Westinghouse Electric and Manufacturing Company in East Pittsburgh

Friday afternoon:

Groups will be shown through the new building of Mellon Institute

Allegheny Observatory located in Riverview Park

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Thomas T. Box, M.D., Chatom, Ala., Washington County Health Officer
 Paul M. Golley, M.D., La Fayette, Ga., County Health Commissioner, Walker-Catoosa District
 Kalman S. von Haitinger, M.D., 417 West Buttes St., Midland, Mich., Director, Midland County Health Dept.
 Carl J. Hawley, M.D., C.P.H., 302 California State Bldg., San Francisco, Calif., Medical Officer, State Dept. of Public Health
 William H. Hatfield, M.D., Cor. 10th & Willow St., Vancouver, B. C., Canada, Director of Tuberculosis Control, Provincial Board of Health
 Robert M. Hursh, M.D., 709 North Third St., Harrisburg, Pa., Health Officer
 Walter B. Johnson, M.D., C.P.H., City Hall, Cumberland, Md., Assistant Health Officer
 Robert A. G. Jones, M.D., Currituck, N. C., Assistant District Health Officer, State Board of Health
 Richard Kui Chi Lee, M.D., Dr.P.H., 2663 Lowrey Ave., Honolulu, Hawaii, Deputy Health Officer and Director, Services for Crippled Children, Board of Health
 Thomas D. Menser, M.D., C.P.H., Box 703, Colorado Springs, Colo., Director, City-County Health Unit
 Miles D. Ridle, M.D., Shelby, Mont., Health Officer, City of Shelby and Toole County
 John J. Shaw, M.D., State Dept. of Health, Harrisburg, Pa., Secretary of Health
 Irving E. Simmons, M.D., C.P.H., Quincy, Fla., Director, Gadsden County Health Unit
 Ralph J. Sykes, M.D., Weldon, N. C., Health Officer, Halifax County
 James A. Taylor, M.D., D.P.H., Box 390, Abbotsford, B. C., Canada, Medical Health Officer, Fraser Valley Health Unit
 Arthur F. Williams, M.D., 220 East Beaver Ave., Fort Morgan, Colo., Health Commissioner, City of Fort Morgan and Morgan County

Laboratory Section

- Reed M. Broadbent, B.A., Iron County Hospital, Cedar City, Utah, Bacteriologist, State Board of Health
 Anthony J. Lamberti, M.S., 2418 South Millick St., Philadelphia, Pa. Director, Bacteriology Laboratory, Villanova College
 Mrs. Duncan R. Neilson, M.A., 2133 N.E.

13th Ave., Portland, Ore., Serologist, State Board of Health

- Norman J. Pyle, V.M.D., Lederle Laboratories, 195 N. Middletown Road, Pearl River, N. Y.

Vital Statistics Section

- Stuart T. Friant, Michigan Dept. of Health, Lansing, Mich., Director, Bureau of Records and Statistics
 Myra E. Hilpert, A.B., 611 South Capitol Ave., Lansing, Mich., Public Health Statistician, Michigan Dept. of Health
 Helen R. Parker, B.Com., 512 Linden Ave., Victoria, B. C., Canada, Statistician, Division of Vital Statistics, Provincial Board of Health
 Noel R. Rawson, M.B., D.P.H., Dept. of Health and Public Welfare, Legislative Bldg., Winnipeg, Manitoba, Canada, Director of Vital Statistics

Public Health Engineering Section

- John D. Faulkner, B.S., 1824 White Oak Road, Raleigh, N. C., Assistant Engineer, State Board of Health
 Francis de Sales Friel, 1520 Locust, Philadelphia, Pa., Chief Engineer, Albright and Friel, Inc.
 Otto L. Fritz, A.B., City Hall, Room 4, Tucson, Ariz., Chief Sanitarian, Tucson-Pima County Health Service
 A. John Horn, 385-93rd St., Brooklyn, N. Y., Water and Sewage Engineer and Chemist, Pease Laboratories
 Harry M. Ramsey, 610 East Washington St., Lewistown, Mont., Sanitary Inspector, Health Dept.
 Byron N. Souder, M.S., Woods Hole Oceanographic Institution, Woods Hole, Mass.
 Frank J. Tatum, B.S.Ed., 1310 Front Ave., Coeur d'Alene, Idaho, State Sanitarian, Division of Public Health
 George Y. Zane, B.S., Board of Health, Wailuku, Maui, Hawaii, Senior Sanitary Inspector

Industrial Hygiene Section

- Gennaro Basilicato, M.D., Marshall, Mich., W. K. Kellogg Foundation Fellowship
 Louis B. F. Raycroft, 19th St. & Allegheny Ave., Philadelphia, Pa., Coöperating with U. S. Public Health Service on Lead Survey

Frederick W. Sands, Fidelity & Casualty Co.
of New York, 80 Maiden Lane, New York,
N. Y., Assistant Chemist

Food and Nutrition Section

Marie L. Matuschka, B.S., 720 K. of P. Bldg.,
Indianapolis, Ind., Director, Dairy Council
of Indianapolis

Child Hygiene Section

Harold Jacobziner, M.D., 105 Clarke Place,
New York, N. Y., School Physician, Health
Dept.

Public Health Education Section

Irving Gerring, M.S.P.H., 412 Camden Court,
Ann Arbor, Mich., Student, University of
Michigan

F. M. Hemphill, M.Ed., State Dept. of
Health, Austin, Texas, Health Education
Consultant

Harry L. Liss, 535 Fifth Ave., New York,
N. Y., Director, Public Health Bureau,
New York State Optometric Association

Basil C. MacLean, M.D., Strong Memorial
Hospital, Rochester, N. Y., Director

Jean G. McKay, M.A., 180 Claremont, Apt.
63, New York, N. Y., Instructor, Dept. of
Health, San Jose State College

Public Health Nursing Section

Hazel E. Altmann, 321 North Thayer St.,
Ann Arbor, Mich., Student, University of
Michigan

Helen Bodley, B.S., 1811-14th Ave., Greeley,
Colo., District Advisory Nurse, Colorado
Division of Public Health

Vesta Bowden, M.A., 304 North Commercial
St., Trinidad, Colo., Public Health Nurse,
Maternal and Child Health Unit

Miriam K. Christoph, B.S., C.P.H., 402
Court House, Minneapolis, Minn., Director,

Hennepin County Rural Public Health
Nursing Service

Ione Coyle, R.N., A.B., 145 East Idaho St.,
Boise, Idaho, Orthopedic Supply Nurse,
Crippled Children's Service, State Division
of Public Health

Eva J. Dugger, Ph.B., Westminster, Colo.,
Supervisor, Maternity Homes and Hos-
pitals, State Dept. of Health

Winifred M. Mendez, R.N., 17 Taft Ave.,
Santurce, Puerto Rico, Instructor of Pub-
lic Health Nurses, Dept. of Health

Florence J. Woods, R.N., P. O. Box 197,
Seldovia, Alaska, District Public Health
Nurse, Territorial Dept. of Health

Epidemiology Section

LeGrand B. Byington, M.D., C.P.H.,
U.S.P.H.S. Laboratory, 14th Ave. & Lake
St., San Francisco, Calif., Surgeon

Robert F. Korn, M.D., C.P.H., District
State Health Office, Saranac Lake, N. Y.,
Epidemiologist-in-Training

Eugene E. Lamoureux, M.D., State Dept. of
Health, Hartford, Conn., Epidemiologist

Emma H. MacChesney, R.N., State Dept. of
Health, Albany, N. Y., Consultant Nurse
in Communicable Diseases

Unaffiliated

Fred P. Bestgen, M.D., Allen Rumsey Hall,
Ann Arbor, Mich., Student, University of
Michigan

Robert A. Downs, D.D.S., 1120 Olivia St.,
Ann Arbor, Mich., Student, University of
Michigan

Gerhard Hartman, B.A., M.B.A., 18 East
Division St., Chicago, Ill., Executive Sec-
retary, American College of Hospital Ad-
ministrators

Merl V. Seney, B.S., Box 196, Butte, Mont.,
with Parke Davis & Co.

Alexander Witkow, M.D., 702 Ocean View
Ave., Brooklyn, N. Y.

APPLICANTS FOR FELLOWSHIP

(Additional to names published in August *Journal*)

In accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Eligibility, and the Governing Council will take place between now and the time of the Pittsburgh Annual Meeting.

Health Officers Section

James B. Black, M.D., Dr.P.H., Director,
Rutherford County Health Department,
Murfreesboro, Tenn.

George A. Hays, M.D., Executive Health
Officer, Flint, Mich.

Walter N. Kirkman, Chief, Division of Per-
sonnel and Accounts and Secretary, State

Board of Health, Baltimore, Md.
Winston H. Tucker, M.D., Ph.D., Commissioner of Health, Evanston, Ill.

Laboratory Section

George P. Berry, M.D., Consultant, Rochester General Hospital, Rochester, N. Y.
Meridian R. Greene, Sc.D., Instructor in Bacteriology, University of California, Los Angeles, Calif.

John F. Kessel, Ph.D., Professor of Bacteriology and Parasitology, School of Medicine, University of Southern California, Los Angeles, Calif.

Ralph S. Muckenfuss, M.D., Director, Bureau of Laboratories, Department of Health, New York, N. Y.

Leland W. Parr, Ph.D., Professor of Bacteriology, Medical School, George Washington University, Washington, D. C.

Cassandra Ritter, M.A., Bacteriologist, Water Laboratory, State Board of Health, Lawrence, Kansas

Vital Statistics Section

Willis C. Beasley, Ph.D., Psychologist, U. S. Public Health Service, Washington, D. C.

Martin B. Woodward, M.D., C.P.H., Director, Bureau of Vital Statistics, State Department of Health, Columbia, S. C.

Industrial Hygiene Section

Anna M. Bactjer, D.Sc., Associate in Physiological Hygiene, Johns Hopkins School of Hygiene and Public Health, Baltimore, Md.

Child Hygiene Section

Howard B. Mettel, M.D., Director, Bureau of Maternal and Child Health, State Board of Health, Indianapolis, Ind.

Public Health Nursing Section

Mary E. Tennant, B.Sc., Director of Nursing, International Health Division, Rockefeller Foundation, New York, N. Y.

Unaffiliated

Jack G. Baker, Chief, Bureau of Foods and Drugs, Department of Public Health, San Diego, Calif.

Charles N. Leach, M.D., C.P.H., Field Director, International Health Division, Rockefeller Foundation, New York, N. Y.

DECEASED MEMBERS

Joseph S. Caceres, Hilo, Hawaii, Elected Member 1930

P. P. Causey, M.D., Courtland, Va., Elected Member 1932

Clifford Charlock, Hilo, Hawaii, Elected Member 1920, Elected Fellow 1924

Hoyt E. Dearholt, M.D., Milwaukee, Wis., Elected Member 1910, Elected Fellow 1923

H. E. Ferguson, M.D., Toronto, Ontario, Canada, Elected Member 1923

Louis H. Fligman, M.D., Helena, Mont., Elected Member 1935

Alfred Friedlander, M.D., Cincinnati, Ohio, Elected Member 1926

Dr. Jos E. Germain, D.P.H., Rimouski, P. Q., Canada, Elected Member 1931

Drew R. Handley, M.D., Edinburg, Texas, Elected Member 1931

William F. Lunsford, M.D., Kansas City, Kansas, Elected Member 1934

John Ritchie, Malden, Mass., Elected Member 1912

Robert C. Robertson, Delhi, N. Y., Elected Member 1937

William H. Seemann, M.D., New Orleans, La., Elected Member 1933

Morris S. Wiener, D.D.S., Brooklyn, N. Y., Elected Member 1938

Adele E. Yoe, Louisville, Ky., Elected Member 1937

CORRECTION

An article by Leroy W. LaTowsky, M.D., appeared in the August *Journal*, beginning on page 912. The work reported therein was done in the Pathology Department of the University of Nebraska College of Medicine, under the direction of J. Perry Tollman, M.D., and E. L. McQuiddy, M.D., not at Dr. LaTowsky's present location—the Philadelphia General Hospital.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, when keyed, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y., identifying clearly the key number on the envelope.

POSITIONS WANTED

HEALTH OFFICERS

Physician, experienced in health administration of cities and states, will consider attractive opening in maternal and child health or health education. A343

Experienced physician, administrator, epidemiologist, and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, aged 33; M.D., Minnesota; Dr.P.H., Johns Hopkins; has served as epidemiologist in large city and director of county health unit, with 7 years' public health experience; will consider position in public health administration or epidemiology. A432

Physician, aged 39; M.D. and Dr.P.H., Yale University; with excellent training in medicine, pediatrics, and epidemiology, now specializing in public health education, will consider appointment in health education or administration. A366

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; now employed, is available as venereal disease control officer. A363

Physician, M.D., Syracuse University; M.P.H., Harvard; postgraduate studies in bacteriology and immunology, will consider position as health officer or epidemiologist. Has served as director of county health unit, director of industrial hygiene and medical statistics and venereal disease field survey officer. A305

HEALTH EDUCATION

Well qualified woman in health education wishes position as health coördinator or health counselor. Has wide experience, and Ph.D. from New York University. H236

Young woman, Ph.D., Columbia Uni-

versity, splendid background of experience in health education, will consider position as director of public health education. H294

Young woman, M.A., Health Education, Teachers College, Columbia; with splendid international experience, seeks position as director of health education. H369

Young woman, experienced teacher in health education, with M.S. in Public Health and Hygiene from University of Michigan, seeks position as health coördinator. H398

LABORATORY

Broadly experienced laboratory director with excellent background, now employed southern state, seeks responsible position in laboratory work or teaching of bacteriology, immunology, and pathology. L426

Capable research worker, Ph.D., trained at University of Southern California and Pasteur Institute, seeks position directing laboratory, in research work or field investigation. Has taught bacteriology, directed state hygiene laboratory and hospital laboratories. L315

MISCELLANEOUS

Experienced teacher in bacteriology and public health; Ph.D., Cornell; now professor in grade A medical school, will consider teaching, executive, or administrative position. M327

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

Engineer with good training and experience in water treatment, sewage plant operation and in research, wishes position as superintendent. Can go anywhere. E422

Public health engineer, B.S. in Civil and Sanitary Engineering; C.P.H., University of North Carolina; 3 years' experience with state department of health

as field supervisor during which time he was in charge of shellfish sanitation; also experienced as district sanitarian; seeks position in public health engineering field. E430

Physician with postgraduate studies in public health at the University of Michigan, seeks employment in public health field. Has served in the Division of Maternal and Child Health of State Department, assistant director of a state health department, and state health commissioner. M309

Experienced director of milk control, food and sanitation and industrial hygiene. B.S. degree and well known

record directing such work in two major cities and one state. References prominent public health personalities. M434

Engineer with B.S. degree and drafting ability, and with U. S. Public Health Service experience in sanitation and malaria control, desires position in sanitation and general public health work. Can go anywhere. E433

Young woman statistician, B.S. in Education, University of Pennsylvania; M.S.P.H., University of Michigan; experienced as secretarial, research and statistical worker in school of public health, desires position in the public health field. S431

Situations Open

PUBLIC HEALTH PHYSICIAN—Southern rural district; physician sympathetic with missionary program preferred; woman eligible; \$2,700. 90-PH, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH PHYSICIAN—For appointment to student health staff in exclusive junior college for women; excellent training internal medicine required; M.S. or Ph.D. in addition to M.D. desirable; woman physician considered. 91-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH PHYSICIAN—Young physician with good medical background, interested in obtaining public health training; salaried appointment at end of month in field; man of English, Irish, or Scotch ancestry preferred. 92-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH PHYSICIAN—Capable and qualified to head department of maternal and infancy work on state board; East. 94-PH, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH PHYSICIAN—Co-educational college having 5 full-time physicians on student health staff; college hospital has 50 beds; opportunity for advancement; \$200; 9-month appointment. 93-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—Interesting tuberculosis follow-up program including bedside nursing service; graduate nurse with both public health and tuberculosis experience preferred; \$115-\$120, plus \$20 car allowance; city of 40,000; North. 95-PH, Medical Bureau, Palmolive Building, Chicago.

SCHOOL NURSE—Large state teachers' college; duties involve actual health work with students; some teaching; \$900-\$1,100, maintenance; 10½ month appointment. 96-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—Public health nurse, for school health service; Michigan. 97-PH, Medical Bureau, Palmolive Building, Chicago.

Situations Wanted

CERTIFIED PUBLIC HEALTH NURSE—B.S. in Education; M.S. in Public Health; experience includes teaching and directorship school of nursing, public health education and research; publications on topics related to public health problems; would like college teaching appointment including opportunity to complete few remaining hours for Ph.D. 98-PH, Medical Bureau, Palmolive Building, Chicago.

HEALTH EDUCATOR—A.B., physical education; M.S., public health; Ph.D., health education; desires appointment allowing full scope for exceptional preparation and experience; would consider opportunities in community hygiene, public health education, or position as health counselor or coordinator; at present serving as director health

education for national organization in large city. 99-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH PHYSICIAN—B.S. and M.D. degrees eastern schools; C.P.H., Johns Hopkins School of Hygiene; 5 years chief epidemiologist state department of health. 910-PH, Medical Bureau, Palmolive Building, Chicago.

BACTERIOLOGIST—B.S., M.A. and Ph.D. degrees, state university, 10 years, teaching and research, including instructorship state laboratory of hygiene; would like research appointment in public health laboratory, or university teaching connection affording unusual research opportunities. 911-PH, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

NEW OFFICERS OF WESTERN BRANCH, A.P.H.A.

AT its Tenth Annual Meeting held recently in Oakland, the Western Branch of the A.P.H.A. elected the following officers to serve for the ensuing year.

President—Frederick D. Stricker, M.D., Portland, Ore.

President-Elect—W. P. Shepard, M.D., San Francisco, Calif.

Vice-President—James S. Cull, M.D., Victoria, B. C., Canada

Vice-President — Edith Kuhns, Helena, Mont.

Vice-President—I. O. Church, M.D., Oakland, Calif.

Secretary—W. Ford Higby, San Francisco, Calif.

Treasurer—Guy S. Millberry, D.D.S., San Francisco, Calif.

Chairman of Executive Committee—W. L. Halverson, M.D., Pasadena, Calif.

EDUCATION OF THE PUBLIC IN HEALTH

A NEW course, designed to train school supervisors, and especially supervisors of education in health, in the important technic of educating the public concerning the protection and promotion of health will be offered at the Harvard School of Public Health beginning in September.

The course, open to college graduates and extending one or two years, has been planned in recognition of the growing realization that those who are engaged in health education work must not only understand individual health measures, but they must also know what public health is, what its aims are, and what administrative measures are used in the fulfillment of its aims. Because it is equally essential that the student understand educational technics, the Harvard Graduate School of Education will coöperate with the Harvard School of Public Health in giving this new course.

There will be no prescribed curriculum; each student will be assigned a personal program after an individual conference to determine his or her needs, in the light of prior training and experience. Credit may be granted for previous academic work in public health and in educational methods, and for experience in the field.

The training offered in this course is based on the principle that the person going into the field of health education needs first of all a basic knowledge of anatomy, physiology, and the fundamental medical sciences. He will need to know the diverse functions of health departments and how such departments are organized. The student, will, therefore, according to his individual needs, be assigned to work in the Harvard School of Public Health, in the Harvard Graduate School of Education, in the Harvard Faculty of Arts and Sciences, in Radcliffe College and in the Harvard Medical School.

NEW YORK CITY HEALTH DEPARTMENT PROPOSES WIDE EXPANSION OF SERVICES

ON August 15, Dr. John L. Rice, Commissioner of Health of New York City, submitted to the City Planning Commission a capital budget for the period 1940-1945. For the Department of Health he proposes the construction of 14 health centers and 22 substations in the various boroughs at a cost of \$7,450,000. An additional request for \$300,000 to complete pending projects brings the total to \$7,750,000.

Before the same board, Dr. Thomas A. Gonzales, Chief Medical Examiner, asked for \$500,000 for an Institute of Forensic Medicine near Bellevue Hospital to train law and medical students in the investigation of crime and the presentation of evidence in courts.

NEW HEALTH OFFICER IN MICHIGAN

THE appointment of Henry Allen Moyer, M.D., of Charlotte, Mich., as State Health Officer, succeeding Don W. Gudakunst, M.D., Dr.P.H., was effective August 1.

CHIROPRACTOR CONVICTED

IT has been reported by George C. Ruhland, M.D., Health Officer of the District of Columbia, and Secretary of the Commission on Licensure of the Healing Arts Practice Act, that on July 27, I. Moton Johnson, a local chiropractor, was convicted of practicing medicine without a license and sentenced to 60 days in jail.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY ESTABLISHES PUBLIC HEALTH ENGINEERING COURSE

THE establishment, at the Massachusetts Institute of Technology, Cambridge, Mass., of a graduate course in public health engineering has been announced by Dr. Samuel C. Prescott, Dean of Science and head of the Department of Biology and Public Health.

The course, which will begin with the opening of the school year on September 25, will lead to the degree of master of science in one year, and will be open to qualified men of outstanding scholastic attainment and professional promise who are graduates in engineering of a recognized school or college. Candidates must have had at least one year of experience with a city, county, or state department of health, the U. S. Public Health Service, or some other recognized health agency.

Professor Murray P. Horwood, of the Department of Biology and Public Health, will direct the courses in public health engineering and vital statistics, while Professor T. R. Camp, of the Department of Civil Engineering, will give the course in hydraulic and sanitary engineering and sanitary de-

sign. The courses in health department practice and industrial hygiene will be given by Professor Clair E. Turner, and the course in sanitary biology by Professor Marshall W. Jennison. Students will be required to present a satisfactory thesis dealing with some original investigation.

JOHN RITCHIE

JOHN RITCHIE, of Malden, Mass., Charter Fellow of the American Public Health Association, Health Commissioner of the City of Boston 1908-1910, died suddenly on July 22, at the age of 88. Mr. Ritchie was for 23 years in charge of the collection and distribution of news on astronomy from Harvard for the United States Government. He had one of the largest libraries in the world on conchology, and a famous collection of shells.

He was Associate Editor of the *American Journal of Public Health*, under Dr. Arthur W. Hedrich, from December, 1919, to September, 1921.

He was a fellow and one-time president of the Boston Scientific Society, a member of the Massachusetts Statistical Association, the Massachusetts Charitable Merchants Association, Malden Tuberculosis Association, Boston Malacological Society, and a fellow of the American Meteorological Society.

PERSONALS

Central States

DR. CARLE W. BEANE, of West Manchester, Ohio, has been appointed Health Commissioner of Preble County, succeeding Dr. JAMES I. NISBET, of Eaton, resigned. DR. GERALDINE M. H. CROCKER, of Granville, Ohio, has been appointed Health Commissioner of Licking County.

† Member A.P.H.A.

THOMAS E. EYRES, M.D.,† of Des Moines, Ia., the first director of the Polk County Health Unit, organized August 18, 1937, has resigned to engage in private practice.

DR. CHESTER S. HEIMLICH, of Attica, Ohio, has been appointed Health Officer of Seneca County.

DR. IRVIN B. KIEVIT, of Medina, Ohio, recently resigned as Health Commissioner of Medina County.

DR. LLOYD E. OVERHULSE, of Holgate, Ohio, has been appointed Health Commissioner of Henry County, to succeed JULIUS R. BOLLES, M.D.,† of Napoleon.

HARRY WAIN, M.D.,† formerly of Chicago, has been appointed Health Officer of Sidney and Shelby County, Ohio.

Eastern States

DR. RALPH S. BELMONT, formerly Associate Medical Officer, U. S. Veterans' Administration, West Los Angeles, Calif., has been appointed Health Officer of Sanford, Me.

DR. ROBERT E. ELLEGOOD, of Dover, Del., who has been a member of the State Board of Health for 23 years, has resigned.

ARTHUR C. JOST, M.D.,† of Dover, Del., has resigned as Executive Secretary of the State Board of Health, effective August 10.

Southern States

DR. BENJAMIN R. ALLEN, of Chatham, Va., formerly Health Officer of the Pittsylvania Valley District, has been appointed Health Officer of the Suffolk-Nansemond-Isle of Wight District, succeeding DR. THOMAS SCARLETT.

GEORGE M. ANDERSON, M.D.,† of Morgan, Ga., has been the Health Officer of the Calhoun County, Ga.,

Health Department. It was recently decided to dispense with this Department, for economic reasons.

JOHN B. H. BONNER, M.D.,† has been transferred as Health Officer from Prince George County to the Page-Shenandoah-Warren Health District, with headquarters at Luray, Va.

DR. PAUL W. BOWDEN, of Franklin, Va., has been appointed Health Officer of Southampton County, succeeding the late PETER P. CAUSEY, M.D.,† of Courtland.

DR. WESLEY G. BYERLY, of Statesville, N. C., has been appointed Health Officer of the Burke-Caldwell District Health Department, succeeding WARREN D. CARTER, M.D., C.P.H.,† of Morganton.

GEORGE R. CARPENTER, M.D.,† formerly of Bristol, Va., has been appointed Health Officer of Fairfax County, to succeed EDWARD M. HOLMES, JR., M.D.,† now on the staff of the State Health Department.

FRANCIS J. CLEMENTS, M.D.,† of Stony Creek, Va., has been transferred as Health Officer from Sussex County to the Sussex-Prince George Health District, with headquarters at Stony Creek.

DR. ANDREW B. COLLEY, of Tompkinsville, Ky., has been appointed Health Officer of Webster County, to succeed DR. CHARLES M. SMITH, of Dixon, resigned.

HERMAN F. EASOM, M.D.,† of Raleigh, N. C., has resigned as Director of the Division of Industrial Hygiene of the State Board of Health. He will return to the staff of the North Carolina Sanatorium for the Treatment of Tuberculosis, where he was formerly located.

WILLIAM W. FULLER, M.D.,† of Williamsburg, Va., has been appointed Director of the Peninsula Health District, to succeed JACK B. PORTERFIELD, M.D.,† who has joined the

† Member A.P.H.A.

- State Health Department in Richmond.
- ISBIN S. GIDDENS, M.D.,† formerly of Ray City, Ga., has been appointed Health Commissioner of Jenkins County, with headquarters in Millen, succeeding DR. GLENN J. BRIDGES, resigned.
- DR. ROBERT N. GRAHAM, of Del Rio, Tex., has been appointed Health Officer of Val Verde County.
- DR. LELAND J. HANCHETT, Passed Assistant Surgeon, U. S. Public Health Service, has been placed in charge of the Division of Venereal Disease Control of the Florida State Board of Health, relieving DR. LEO C. GONZALEZ, of Jacksonville, while he is taking a postgraduate course in venereal disease control and public health at Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md.
- DR. OLIVER W. JENKINS, of Edison, Ga., has been named Health Commissioner of Bartow County, succeeding DR. ROBERT F. YOUNG, of Cartersville, who resigned to enter general practice in Hope, Ark.
- DR. DANIEL E. LITTLE, of Eufaula, Okla., has been appointed Health Superintendent of McIntosh County.
- DR. JOE W. MAY, of Donna, Tex., was elected Health Officer of Hidalgo County, to succeed the late DREW R. HANDLEY, M.D.,† of Edinburg.
- ALBERT B. MCCREARY, M.D.,† of Jacksonville, Fla., has been appointed Health Officer of Florida, succeeding the late WILBUR A. MCPHAUL, M.D.† Dr. McCreary has been Director of the Bureau of County and District Health Work for the State Board of Health during the past 4 years.
- DR. CHARLES W. McDONALD, of Marianna, Fla., District Health Officer, has been named Acting Health Officer, following the resignation of
- DR. RAYBURN N. JOYNER as Director of the Jackson County Health Department.
- CHRISTOPHER L. MENGIS, M.D.,† of New Orleans, La., formerly Director of the Crippled Children's Division of the Louisiana State Board of Health, has been appointed Director of the Iberia Parish Health Unit, with headquarters at Homer, La., succeeding BERT L. STINSON, M.D.†
- DR. LAILOR A. MORROGH, JR., of Arnaudville, La., has been appointed Director of the Avoyelles Parish Health Unit, succeeding the late LUCIUS W. HOLLOMAN, M.D.,† of Marksville.
- JOHN C. NEALE, JR., M.D.,† of Staunton, Va., has resigned as Health Officer of Augusta County, to take charge of the Southwest District, with headquarters at Abingdon.
- DR. WALDO B. NEWELL, JR., of Enid, Okla., was appointed Superintendent of Health of Garfield County, effective April 1, succeeding the late DR. WILLIAM W. GILL, of Enid.
- CHARLES M. PEARCE, M.D.,† formerly State Health Commissioner of Oklahoma, has been appointed Health Officer of Lake County, Fla., succeeding DR. TERRY BIRD. His headquarters will be in Tavares.
- CARL V. REYNOLDS, M.D.,† of Raleigh, N. C., has been reappointed State Health Officer for another term of 4 years. He was first appointed Acting Health Officer in November, 1934, on the death of DR. JAMES M. PARROTT, and received the regular appointment in May, 1935.
- DR. CHESTER L. RILEY, of Manassas, Va., has been transferred as Health Officer from Prince William County to the Prince William-Stafford Health District, with headquarters at Manassas.
- WYATT E. ROYE, M.D.,† formerly of Richmond, Va., has been assigned to the Alleghany-Botetourt District,

† Member A.P.H.A.

with offices in Covington. He is succeeding JAMES H. GORDON, M.D.,† who has resigned to take graduate work in Philadelphia.

HARRY A. SAUBERLI, M.D.,† of Sevierville, Tenn., has been appointed Health Officer of the Upper Cumberland District, to succeed FRAY O. PEARSON, M.D.,† resigned.

DR. THOMAS SCARLETT, formerly Health Officer of the Suffolk-Nansemond-Isle of Wight District, in Virginia, has been assigned to the Rockingham County Health District, with headquarters in Harrisonburg.

DR. FRANK KASH SEWELL, of Madisonville, Ky., has been appointed Health Officer of Breathitt County.

BERT L. STINSON, M.D.,† of Homer, La., has succeeded DR. WALTER W. POIMBOEUF as head of the Health Service in Claiborne Parish.

VAN C. TIPTON, M.D.,† of Austin, Tex., has been appointed Director of Public Health for San Antonio.

THOMAS B. TURNER, M.D.,† of the International Health Division of the Rockefeller Foundation, has been appointed Professor of Bacteriology at the Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md. During the past 3 years Dr. Turner has been engaged in postgraduate teaching and research in syphilis at the School of Hygiene and Public Health, under the auspices of the Foundation.

VERNON A. TURNER, M.D.,† of Richlands, Va., has been appointed as Health Officer of Augusta County, succeeding JOHN C. NEALE, JR., M.D.,† resigned. Dr. Turner was formerly in charge of the Buchanan-Russell-Tazewell District.

DR. CLARENCE H. WHITE, of Newton, N. C., has resigned as Health Officer of Catawba County. Dr. White will study at Harvard University.

† Member A.P.H.A.

Western States

KATHERINE KING BAKER,† formerly employed with the New Mexico State Department of Health, is now employed as Supervisor of Nurses, City Health Department of San Antonio, Tex.

EDWARD J. DEHNE, of Kellogg, Idaho, has been appointed Health Officer of Clatsop County, Ore., succeeding LENOR S. GOERKE, M.D., C.P.H.†

DR. FRANCIS H. GAMBELL, of Willows, Calif., has been appointed Health Officer of Glenn County, succeeding DR. FRANK M. LAWSON.

LENOR S. GOERKE, M.D., C.P.H.,† of Astoria, Ore., recently Health Officer of Clatsop County, has been appointed Health Officer of Yamhill County.

HAROLD R. HENNESSY, M.D.,† has been appointed Bi-County Health Officer of Sutter and Yuba Counties, Calif. He recently completed a year of post-graduate work in Public Health at the University of California.

DR. CORNELIUS W. LANE, of Crescent City, Calif., has been named to succeed DR. WILSON STEGMAN as Health Officer of Del Norte County.

DR. FRANK I. O'NEILL, of Oroville, Calif., has resigned as Health Officer of Butte County.

DR. ALFRED C. REED, the Director of the Institute of Tropical Medicine of the University of California, has been elected a corresponding member of the Belgium Society of Tropical Medicine.

DEATHS

WILBUR A. MCPHAUL, M.D.,† State Health Officer, of Jacksonville, Fla., died August 1.

DR. WILLIAM J. MAYO, of the Mayo Clinic, Rochester, Minn., died July 28.

Steam isn't nearly as tough on bacteria as it is
on painted walls. Tests show that only one foot
away from the nozzle the temperature will drop
far below the minimum necessary to kill bac-
teria. But steam is plenty tough on walls . . .
quickly causes paint to blister and peel. Repaint-
ing 2 to 3 times a year is expensive.

Diversol is tough only on bacteria. Kills them
quickly . . . yet never causes damage. Want
facts? Write for Research Bulletin.

Viruses of Equine and of St. Louis Encephalitis in Relationship to Human Infections in California 1937-1938

BEATRICE F. HOWITT

*George Williams Hooper Foundation, University of
California, San Francisco, Calif.*

DURING the summer and autumn of 1937, physicians in California reported a number of cases of acute encephalitis, some with a stormy course and others less violent. There were 40 deaths. Most of the cases occurred in the two large Central California Valley regions with the majority from Fresno and Tulare Counties. Fresno reported 13 fatalities, while a milder form, usually with uneventful recovery, occurred in Tulare. During the same seasonal period in 1938 a similar type of disease was recorded showing both the severe and the milder forms. Fresno and Tulare were again affected, with additional patients from Kern County at the extreme southern end of the San Joaquin Valley.

During 1937 brain material was received from 3 fatal cases but although numerous mice and a number of monkeys were inoculated, no virus was recovered. Sera were then collected

through the coöperation of the Fresno and Tulare County Health Departments from many of the recovered patients in the lower San Joaquin Valley districts where the outbreak was the most severe. Sera were also obtained in connection with the State Department of Public Health from other regions in California where some form of encephalitis had been reported. The clinical history of this group¹ has been reported, so this paper will not bear upon that aspect.

It was found that about 56 per cent of the recovered patients in the Fresno and Tulare areas had neutralizing antibodies for the virus of St. Louis encephalitis,² while they were negative for the Japanese B virus and that of lymphocytic choriomeningitis (l.c.m.).*

* These viruses were kindly sent as follows: The Japanese B strain from Dr. S. Kashara of the Kitasato Institute, the St. Louis virus from Dr. L. T. Webster of the Rockefeller Institute, and that of the l.c.m. strain from Dr. C. Armstrong of the National Institute of Health.

Since many of these cases showed clinical pictures similar to those described for the St. Louis type of encephalitis, it was assumed up to and through part of the summer of 1938 that the etiological agents were identical even though no virus had been directly isolated. However, the percentage of positive neutralization tests given seemed much lower than those reported by other workers for sera of recovered cases after the St. Louis outbreak. Wooley and Armstrong³ obtained 94 per cent positive sera from 39 convalescent patients; Webster, Fite, and Clow⁴ 82.5 per cent from 29, and later Muckenfuss, Smadel, and Moore⁵ found 69 per cent definitely positive and 9 per cent doubtfully positive of 126 sera tested from recovered encephalitic patients in the vicinity of St. Louis.

This discrepancy was not easily accounted for at the time and it was not until the autumn of 1938 that it was explained by recovery of the western strain of equine encephalomyelitic virus from the brain of a child at Fresno.⁶ This was followed by isolation of the same type of virus from the blood of a man in Tulare.⁷ With the knowledge that another neurotropic virus could be a responsible agent in this region additional studies were undertaken to determine the extent of the disease in reported encephalitic areas and to ascertain whether a differentiation could be made.

NEUTRALIZATION TESTS WITH HUMAN SERA

During the autumn of 1937 and the first half of 1938, sera were collected from recovered encephalitic patients in the Central California Valley areas exclusive of Kern County, and from a few coastal towns. These sera were mainly from Fresno and Tulare Counties and were tested for antiviral substances against the l.c.m., the St. Louis, and the Japanese viruses, respectively.

A certain number were also used against the poliomyelitic virus. After recovery of the human equine strains, tests were made against the new, very virulent Br variety with all the old sera available from these areas and with more sera collected later in 1938 from Kern and Fresno Counties.

Protection experiments for the encephalitic viruses were performed as follows: Equal parts of serum and the appropriate dilutions of each virus were mixed and held overnight in the refrigerator before inoculating 0.03 cc. intracerebrally into mice. After preliminary titrations and stabilizing of each virus, it was found that under the conditions given the following dilutions were the most advantageous for each type, 2 being employed for each strain and from 3 to 4 mice per serum for each dilution of virus. The dilutions for the encephalitic viruses were made from 10 per cent brain suspensions in a mixture of equal parts of broth (pH 7.5) and sterile distilled water. They were 1-10,000 and 1-50,000 for the St. Louis strain, 1-50,000 and 1-100,000 for the Japanese B, 1-100 and 1-250 for the l.c.m., and 1-1,000,000 and 1-5,000,000 for the Br human equine virus. The original western equine (California) strain was used in the dilutions of 1-10,000 and 1-100,000. Known negative and positive sera were always included with each series. Equal parts of serum and a 1-25 dilution of the 5 per cent poliomyelitic virus were also mixed and kept overnight in the cold before inoculating 1.5 cc. intracerebrally into rhesus monkeys.

Forty-nine, or 47.5 per cent, of 103 sera of the encephalitic group had protective antibodies against the St. Louis strain, although 10 were only weakly positive as shown in Table I. A serum was considered to give a positive neutralization if all the mice employed remained alive for the two dilutions, and weakly positive if they died with

TABLE I
Neutralization Tests on Sera of Encephalitic Cases*

County	No. Cases Tested	Strains of Virus				Positive for Both Types of Virus
		Western Equine Virus (Br Strain)	No. Cases Tested	St. Louis Encephalitis Virus	No. Cases Tested	
Fresno 1936-38	19	3 ⊕ 9 +	23	1 ⊕ 9 +	20	7
		12 (63.1%) +		10 (43.4%) +		7 (35%) +
Kern 1938	26	1 ⊕ 8 +	26	5 ⊕ 8 +	26	5
		9 (34.2%) +		13 (50.0%) +		5 (19.2%) +

Total No.	86	32 (37.0%) +	103	49 (47.5%) +	69	18 (26%) +

* ⊕ = Weakly positive neutralization
+ = Positive neutralization
0 = No neutralization

the strong dilution and survived the weaker. They were negative if all animals died.

Seventy-one of the 103 sera were from cases in the 3 counties of Kern, Tulare, and Fresno, in the lower San Joaquin Valley where the majority of the encephalitic reports occurred; 37 of the 71 sera, or 52.1 per cent, gave some degree of positive protection for the St. Louis virus, the largest number coming from Tulare County and the next from Kern County. There were 2 positive cases and 1 weakly positive from the coastal counties.

Of 86 sera tested from individual cases, 32, or 37.0 per cent, gave either a weakly or a strongly positive neutralization against the Br strain of equine virus: 59 of these came from the 3 designated counties with 26, or 44 per cent, positive. These figures undoubtedly would have been higher if material had been obtained from all the patients showing neurotropic symptoms.

Unfortunately many of the earlier cases disappeared and blood could not be obtained later when the importance of the equine virus for man was ascertained.

There were 6 positive neutralizations with sera from other areas in the more central or the northern parts of the Valley regions and none from the coastal districts (Table I).

That so many sera showed protection tests for these two viruses was probably of some diagnostic significance, but just how much reliance can be placed in such findings may be questioned when on further analysis it was found that a number of sera were positive to both the St. Louis and the equine strains. Of 69 sera tested against the two types, 18, or 26 per cent, showed some degree of neutralization for both (Table I).

To add further to the uncertainty in regard to the value of the neutralization test in these neurotropic cases, 34 sera of the earlier encephalitic series,

which did not include the Kern County group, were tested for antiviral substances against the virus of poliomyelitis; 26, or 78.7 per cent, of these were positive but only 4 to this virus alone. Four were positive only to the St. Louis strain while 12 had antibodies for both viruses. Thirteen of these sera remained and later 2 were found to neutralize the equine strain. There was sufficient evidence, therefore, that, given a certain district, the human serum could harbor antiviral substances for a variety of neurotropic viruses.

From 1934 to 1937 many cases of central nervous system disturbances were reported by physicians from both Kern and Tulare Counties, mainly recorded as poliomyelitis. Many of these people showed only a transient muscular weakness and recovered without residual paralysis. Fresh serum was obtained from 14 of these individuals in Kern County who had been diagnosed as having poliomyelitis in 1934 to 1937 respectively. Five were positive for the St. Louis virus, 6 for the equine, and 3 for both. Taken by years, one of the 4 sera in the 1934 group was positive for the St. Louis strain and none for

the equine. The 2 in the 1935 group showed some neutralization for both viruses, while of the 4 in 1936, 1 serum neutralized the equine and 2 were positive for the St. Louis type. In the 1937 series 3 of the 4 sera reacted to the equine and none to the St. Louis strain.

Some old sera were available from a poliomyelitic group in Tulare County who had been bled in 1936 and 1937, respectively. One person showed clinical symptoms in 1934 and another in 1937, but the majority were ill during 1935 and 1936. Sera from 23 of these individuals were tested in 1938 against the St. Louis virus and 11 (43.4 per cent) showed a positive neutralization, as given in Table III. Sixteen out of 20 (80.0 per cent) neutralized the virus of poliomyelitis, 8 being positive to it alone, and 6 positive to both the latter and the St. Louis strain (Table II). Only 13 of these sera remained that could be tested later against the Br equine virus. One showed a weakly positive reaction while all the others were negative. Most of the sera had been kept for 2 years in the refrigerator, so that it was interesting to note that the antiviral substances to the St. Louis

TABLE II
Neutralization Tests on Different Groups of Individuals

A. Normal Individuals					B. Cases Diagnosed as Poliomyelitis					
Type	Neutralization Test				Region	Neutralization Test				
	No. Tested	Equine Virus (Br)	St. Louis Virus	Equine and St. Louis		No. Tested	Equine Virus (Br)	No. St. Louis Tested	Equine and St. Louis

strain still remained. None of the people with sera positive to the St. Louis virus showed any residual paralysis and all had the onset since 1934. Of the negative cases 5 had some paralysis but had generally recovered. One in the group diagnosed in 1923 had residual paralysis and his serum did not neutralize the St. Louis strain.

In order to determine to what extent the antiviral substances for these viruses might be present among groups of people such as normal contacts, normal non-contacts, and recovered poliomyelitic patients from other than the Central Valley areas, various people were bled and their sera tested for antibodies.

In a group of recovered poliomyelitic cases from around the Bay Region, 23 sera failed to neutralize the St. Louis virus while 20 were negative to the Br equine strain (Table III). Most of the convalescents showed some form of residual paralysis, although 4 or 5 were apparently normal.

Of 26 normal non-contacts (Table III) including nurses, doctors, and laboratory workers in the Bay Region, none gave any neutralization for the equine strain. One was weakly and another strongly positive for the St. Louis virus. The former was a dentist in close contact with many people and the latter had lived in Kern County before training as a nurse in San Francisco.

A similar number of sera were tested from a group of normal individuals, doctors and nurses in the Valley areas who had had some contact with human encephalitic cases during the past few years, including also a group of veterinarians who had histories of previous contact with sick horses. All were negative to both viruses.

Another small group was included from Tulare County. These people had all been associated in some way with S, the man from whose blood the equine

virus had been recovered. Although one of the 11 sera was positive to the latter strain, 6 showed neutralization for the St. Louis virus, indicating contact to the latter among the general population in this region. No history was obtained from the person positive to the equine strain.

To summarize, it would appear that of a total of 63 apparently normal individuals as far as encephalitis was concerned, 8 had neutralizing antibodies for the St. Louis virus and 1 for the equine. All but 1 of the 9 had lived in the San Joaquin Valley. Of 47 tested for the equine virus, and 60 for the St. Louis strain among groups of people diagnosed as having had poliomyelitis, the only positive sera for either virus were from those residing in the San Joaquin Valley.

To confirm further the neutralization experiments on certain of the sera that were positive to the Br or new human equine strain, the tests were repeated using the original western equine (Californian) virus. Fourteen of the 21 sera, 16 of which are given in Table IV, were also strongly positive to this strain, 4 others were only weakly positive, although they had been stronger with the Br strain, while 3 were negative. The latter had reacted only very slightly to the Br virus so the amount of the antibodies could not have been very appreciable. Six sera negative to the human strain were also negative to the Californian variety. On the whole, however, the relationship between the two types of virus seemed fairly well established by this cross-neutralization with sera from cases having a history of some disturbance of the central nervous system.

No protective substances for the l.c.m. and the Japanese B viruses, respectively, were demonstrated in any of the sera of the 1937 series. These tests were discontinued for the group collected later.

PERSISTENCE OF ANTIVIRAL SUBSTANCES

It is interesting to note that so far, with one exception, the antiviral substances to the Br equine strain appeared only in sera from individuals having had some definite disturbance of the central nervous system, either a recognizable encephalitis or some intermediate form difficult to distinguish from poliomyelitis. The one exception was in a person who had been in contact with a known case of human equine encephalomyelitis and lived in an apparently infected area, but whose earlier history was not ascertained.

On the other hand, antibodies for the St. Louis virus were found not only in those people with some neurological disturbance but from a certain number of apparently normal individuals, indicating perhaps a difference in the route of infection for the two viruses.

Owing to the distance between the source of material and the laboratory facilities, collection of the sera during the early part of the disease was not often achieved, so that one is left in doubt as to which virus might have been the etiological agent in many cases where the antibodies were posi-

tive for both types. In 4 instances, however, serum was obtained in 5 to 8 days and in 1 or 2 weeks after entrance to the hospital, and then again after recovery (Table III). Protective substances for the equine strain were either absent or very weakly positive at first, becoming stronger after several weeks. Those to the St. Louis strain were also present in 3 of these sera but showed an initial potency, indicating that they had probably been acquired before the attack of encephalitis.

The antibodies appeared, perhaps weakly, as early as 8 days after the onset in those cases with a good recovery. With the sera examined from the groups shown in Table III, positive neutralization for the equine virus could be obtained at various periods up to one year after the onset. In 7 instances they were still present after 1 year or a little over, in 1 case at 2 years and in 2 others after 3 years and 2 months since recovery. There is every reason to believe, therefore, that the antiviral substances, if once established for this particular virus, may remain in the human serum for as long a time as for any other neurotropic virus disease. They were also found to

TABLE IV
Positive Neutralization Tests According to Age Distribution

County	Type of Virus	Total No. of Cases Tested	Under 5 Years	Total No. of Cases Tested	5 to 20 Years	Total No. of Cases Tested	Over 20 Years
Fresno 1937-38	Western Equine (Br strain)	3	2 + (1 weakly)	6	3 +	14	7 +
	St. Louis encephalitis		1 +		2 +		7 +
	Both viruses		1 +		1 +		4 +
Kern 1938	Western Equine (Br strain)	7	4 +	8	2 + of 7 tested	11	3 +
	St. Louis encephalitis		1 +		6 +		6 +
	Both viruses		0		2 +		4 +
Tulare 1937-38	Western Equine (Br strain)	1	0	12	1 + out	9	4 +
	St. Louis encephalitis		1 +		6 +		7 +
	Both viruses		0		1 +		2 +

persist in the stored material. A few sera collected in August, 1937, were found to be positive upon testing in February, 1939, about a year and a half. There was no way of knowing, however, whether the antibody content had depreciated considerably, since no tests for the equine virus had previously been made. It was also noticed that the antiviral substances for the St. Louis virus persisted after about 2 years' storage. In several instances titrations were made on the same sera at different intervals, and a decline in titer was noticed.

Because of the presence of protective substances for the two different viruses in the blood of many of these encephalitic patients where clinical symptoms were similar, it is difficult to decide as to the etiological factor, especially where the actual virus had not been found. It seems very probable, however, that antiviral bodies for the St. Louis strain were present in many of the patients for some time. Many of the people belonged to the transient labor group and probably had acquired these antibodies in Missouri, Oklahoma, or Texas. If that were so, one would expect the greater number positive for the St. Louis strain to be found among the older age groups. Also one would expect the appearance of both types of antibodies in one serum among the latter group and the presence of one or the other among the younger people. This view seems justified as observed by reference to Table IV where the positive neutralization tests against the two viruses are tabulated for the counties of Kern, Tulare, and Fresno, according to the age distribution. As the age increases the number of positive tests to both strains also increases and there are more positives to one type of virus alone among the younger children than among the adults. There were, however, more encephalitis cases among the adults in these particular

groups, 34 over 20 years of age, 26 from 5 to 20, and 11 under 5 years, with a predominance of the positive tests for the St. Louis virus (20 of the 34) among the oldest group. More positive neutralizations to the equine strain than to the St. Louis appeared among the younger people. One therefore may be justified in assuming that where a positive neutralization has been obtained for a particular virus alone among the children it is most probably the etiological agent of the neurotropic disturbance involved.

EPIDEMIOLOGY

Since 1934, in California there has been noticed a change in the type of labor population inhabiting the two Central Valleys where the majority of the large agricultural industries are located. Where formerly the incoming laborers had been Mexicans, Filipinos, or southeastern Europeans, now they were migrants from Missouri, Oklahoma, or Texas, who were unable to cope with the financial depression and the dust storm problems at home and were now looking for the hoped-for land of opportunity. Coming in largely by the southern route they settled in the Valley regions from Kern County at the southerly end, working northward with the change of crops (Figure II). Most of them were poor, the living quarters most inadequate and sanitation far from favorable. In consequence whatever diseases occurred in the vicinity usually appeared among this group. Among the people coming to the Kern County Hospital to be bled for the neutralization test after recovery from a neurotropic disturbance, 14 out of 37 had some connection with Oklahoma, Missouri, or Texas. The whole subject of the migrant labor problem in California has been very graphically presented by a recent article in *Fortune*.⁸ Residents from the middle and southwestern states have

MAP 1.

Distribution of Places in California where were Cases of Encephalities with Serums having a Positive Neutralization to the Virus of Western Equine Encephalomyelitis. 1937-1938.

gradually been moving toward the coast since 1930, with the greatest influx after 1934.

As noted, 1934 was the earliest date available when diseases of the central nervous system were reported in people whose sera were later shown to have neutralizing antibodies for the St. Louis virus. For the population from Kern County northward, all of these early cases were in the Central Valleys. From then on the number showing these antibodies seemed to increase and more frank cases of encephalitis were recorded for these areas. This was especially noticeable for the Tulare region where the sera obtained were more often positive to the St. Louis virus

than to the equine (Table I). Did the migrants bring in the St. Louis strain and start an endemic area for this disease, which in many instances might be clinically difficult to distinguish from non-paralytic poliomyelitis? and then were certain other conditions superimposed that initiated an outbreak of yet a third type of central nervous system disturbances which could be particularly invasive for the rural population?

From certain epidemiological observations it seems likely that from Kern County northward some such factors have been at work during the past 4 or 5 years. Poliomyelitis was undoubtedly already endemic in many of the Valley towns. From 1934 to 1937 the

migration westward occurred in the largest proportions and with it most probably a few cases of the St. Louis type of encephalitis that may have helped immunize some of the population. In addition, a third neurotropic virus, that of equine encephalomyelitis, acquired significance for human welfare.

Previous to 1937 there had been a series of dry years throughout this part of the state, but during 1937 and 1938 the rainfall was unusual. The snow was heavy in the mountains, there were late rains with subsequent floods in the river areas and dry lakes were filled, tules grew where they had not been for years and much water was present in the central lands where the larger towns are found. As a result many mosquitoes appeared and were everywhere noticeable. Although no insect has as yet been actually implicated in the spread of the equine disease in the field, yet from the experimental work of Kelser,⁹ Merrill and Ten Broeck,¹⁰ Madsen, Knowlton, and Rowe¹¹ and Giltner and Shahan,¹² it seems most probable that a biting insect such as the mosquito is an important factor in transmission of this virus. They have all been able experimentally to produce the disease by means of several species of infected mosquitoes.

Whether or not a vector is responsible for the dissemination of the St. Louis virus is still an open question. Because of the negative results for mosquito transmission by Leake, Musson, and Chope in 1933,¹³ the respiratory route of infection has been especially favored for this disease, largely because of the ease of intranasal transmission in mice. However, Webster, Clow, and Bauer¹⁴ demonstrated later that *Anopheles quadrimaculatus* if infected can retain this virus for life, while Lumsden¹⁵ has presented epidemiological evidence to show that *Culex pipiens* might

have been implicated during the St. Louis epidemic in 1933. Subsequently Mitamura and Yamada, as reviewed by Inada,¹⁶ have experimentally transmitted the virus of the Japanese B encephalitis by means of both *Culex pipiens* and *Culex tritaeniorhynchus*.

Although the disease of equine encephalomyelitis has been endemic among the horses in the San Joaquin and Sacramento Valley regions for many years, especially recognized since 1930 when the virus was first isolated by Meyer, Haring, and Howitt,¹⁷ there has been no noticeable association with any similar form in man. It is true that 3 cases occurring in veterinarians or persons in close contact with horses had been reported in 1932 by Meyer,¹⁸ but there was no associated outbreak among the general population. The largest epizootic among horses had appeared from 1930 to 1932 and scattered cases were subsequently reported but not in epidemic proportions. For that reason after the first appearance of a definite human encephalitis around Fresno in 1937, no connection was made between the two forms. It now seems apparent, however, that the virus was the causative agent of many of the cases and probably of the fatal ones, especially as at least 3 of the patients in Fresno County and 2 in Kern who were ill in 1937 had antibodies for the equine type alone when tested in 1938. Since no virus was actually recovered from any of them in 1937, the true nature of the disease remained unrecognized until the following year.

From reports of the veterinarians in both Kern and Fresno Counties in 1938 there was no unusual number of sick horses but the mosquitoes were very prevalent. One might wonder, if the mosquitoes were the vectors in the equine outbreak in 1930, why human cases were not recorded and why they should now appear when the disease in

horses had subsided. One can only surmise that the unusual climatic conditions have brought the insects closer to the human population areas. As shown in the map the people with encephalitis having positive antibodies for the equine virus were found in the drainage regions, in the central portions of the valleys and mainly on the outskirts of the larger towns. Many cases of encephalitis were reported from the cities of Bakersfield and Fresno, but the individuals usually lived in streets bordering on the outskirts, near open fields where the wind could waft insects from the undrained areas. There is also the possibility that the unusual climatic conditions had encouraged the increase of some new vector common to both man and animals taken in combination with perhaps another animal reservoir than the horse.

By the courtesy of Henry Bye of the Kern County Health Department, Figure I was drawn from figures taken from their records for the human cases and from those of Dr. Edwards for the equine. A record is given of the monthly appearance during 1938 of human and of equine cases in the same localities. Apparently only 10 horses were treated in areas where human encephalitic cases were found, 8 of which were within a 4 mile radius of Bakersfield, and the others not so many miles away. The peak for the horses came in July, and a month later for man. The disease in the animals seemed to

drop off and then re-occur later, with another rise in October. The number of equine cases was so small, however, that one cannot draw definite conclusions.

Most of the human encephalitic cases considered to be of the equine type by reason of the neutralization test or the isolation of the virus, have come from the areas shown in the map. In Kern County 5 patients were within the 4 mile radius of Bakersfield or if in the town were on the outskirts, 2 were from Buttonwillow, 2 near Edison, while 6 cases of encephalitis were reported from the Arvin district with 2 of the equine type. In Fresno County there were 5 patients within a 5 mile radius of Fresno and the others from a group of closely associated small towns not far from Fresno, 3 from Sangar, 2 from Kerman, and 1 each from Selma and Del Rey. Several individuals were reported as having encephalitis at Fowler but no definite results were obtained. In Tulare the people were also from associated districts where mosquitoes were most prevalent.

It seems very probable that a number of the cases reported as encephalitis in the Valley counties northward were also of the equine type, but unfortunately material was not available from them again and most of the sera first collected were exhausted. However, sufficient evidence was obtained from the few sera on hand to indicate a more general distribution of the equine virus in man throughout both of the valley regions than may have been suspected. Since the epizootic of 1930 and 1931 was widespread throughout both the Sacramento and San Joaquin Valleys (morbidity at that time being about 6,000 horses with an average mortality of 47 per cent, according to Meyer¹⁸), it is not unreasonable to suppose that the human form had been present, now that proof has been given of the infectiousness of this virus for man. Two

FIGURE I

NUMBER OF REPORTED CASES OF EQUINE ENCEPHALOMYELITIS FOR HORSES AND MAN IN KERN COUNTY 1938

of the 3 human cases reported by Meyer in 1932¹⁸ came from the Sacramento district and the third from Madera above Fresno. Serum was obtained again from the latter person 6 years after recovery but gave weakly positive protection for the Br strain.

Since nearly all of the positive cases in the counties of the lower San Joaquin Valley had possibilities of exposure to some form of vector but not necessarily to sick horses, especially in regard to the infants, it seems very likely that a biting insect has been the responsible agent for the recent outbreak of the equine disease.

DISCUSSION

During 1938 the actual recovery of the equine virus from fatal cases of human encephalitis was reported first by Fothergill, Dingle, Farber, and Connerly¹⁹ and Webster and Wright²⁰ for the eastern form in Massachusetts, and then by Howitt⁶ for the western in California. A more detailed account of the eastern outbreak was then given by Feemster²¹ and also by Wesselhoeft, Smith, and Branch²² who reported the histories of 8 fatalities in Massachusetts with recovery of the virus from 5. At about the same time Eklund and Blumstein²³ in Minnesota presented a clinical account of cases of human encephalitis closely associated with an equine epidemic during 1937. Since neutralizing antibodies for the western equine virus were found in the sera of 3 recovered patients, this strain was considered to be the etiological agent.

Prior to these reports the equine disease had not been incriminated for man except for the 3 cases already described by Meyer in 1932. It seems highly probable, however, that many acute cases of encephalitis without recovery of an active agent could have been attributed to this disease and that both non-paralytic poliomyelitis and the St. Louis type of encephalitis were confus-

ing factors in many instances. It was interesting that the latter virus was evidently intermixed in California in such a way as to cause confusion in differentiation. Since the actual virus has not as yet been recovered from these areas, it is still uncertain whether or not true cases have been present. It has been shown by Wooley and Armstrong³ and by Muckenfuss, Smadel, and Moore⁵ that antibodies to this virus may be found among the general population in an endemic area, comparable to what has been reported for poliomyelitis. For this reason, as demonstrated by Smith and Moore,²⁴ too much diagnostic significance should not be placed on their presence in acute cases unless the serum of the patient is negative during the early stages of the disease and later shows a rise in antibody content after recovery. So far in the California areas affected there has not been any generalized immunization to the equine virus, because only those persons showing an acute disturbance of the central nervous system developed antiviral substances. Normal people and those having acquired poliomyelitis in the Bay Region were all negative, with the exception of one individual in the San Joaquin Valley whose history was unknown.

This differentiation in the presence of antibodies to both viruses leads one to suspect that the equine form has rather recently become of human significance, probably because of the sudden appearance of a new vector or perhaps a new reservoir host. The eastern virus has lately been recovered in nature from both the pigeon²⁵ and the pheasant²⁶ so that some such host may also be present in the West. Whatever is later proved, it seems warrantable to assume that at present the occurrence of protective substances for the western equine virus has some diagnostic value in the Californian regions affected and that this disease

first became of marked significance to human welfare during 1937. Sporadic cases very likely occurred throughout the northern and central valleys during the previous years but were reported either as non-paralytic poliomyelitis or as some form of encephalitis of unknown etiology. Sera were positive for 2 cases having their onset in 1935 and for 1 in 1936. A more complete survey of the population would undoubtedly show a larger number of positive tests. On the other hand, the simultaneous presence in a serum of antibodies for the St. Louis virus may not have as much value because of a more generalized immunization in certain Valley areas.

SUMMARY

1. An outbreak of the western type of equine encephalomyelitis occurred among the human population of the two large Central Valleys in California during 1937 and 1938.

2. The western strain of the equine virus was recovered from the brain and the blood, respectively, of 2 human cases of encephalitis in this region. Both strains were shown to be immunologically and serologically similar to the virus of equine origin.

3. Total number of cases of encephalitis tested throughout northern and central California:

Positive neutralization to the St. Louis virus: 49 (47.5 per cent) out of 103 sera.

Positive neutralization to the equine virus (Br): 32 (37.0 per cent) out of 86 sera.

4. Number of cases of encephalitis tested in Fresno, Tulare and Kern Counties only:

Positive neutralization to the St. Louis virus: 37 (52.1 per cent) out of 71 sera.

Positive neutralization to the equine virus (Br): 26 (44 per cent) out of 59 sera.

5. Positive neutralization to both viruses: 18 (26 per cent) out of 69 sera.

6. Of a total of 63 apparently normal individuals, contacts and non-contacts, residing in both the Bay Region and the Valley districts, 8 had neutralizing substances for the St. Louis virus and 1 for the equine. With the exception of 1 for the St. Louis type, all of the positive group resided in the San Joaquin Valley.

7. Of a total of 47 individuals tested for equine virus and 60 tested for the St. Louis strain among groups diagnosed as having poliomyelitis in both the Bay Region and in

the Valleys, the only positive sera for either virus were from those in the San Joaquin Valley.

8. Fourteen of 21 sera positive to the Br equine strain also gave strongly positive neutralization with the western virus of equine origin (Californian), while 4 were weakly positive.

9. Neutralizing antibodies for the Br equine virus could be obtained as early as 8 days after onset of the disease and were found in some individuals after 1, 2, or even 3 years since recovery. Positive sera for both the St. Louis and the equine strains retained their neutralizing power after storage for from 1 to 2 years, but potency was decreased.

10. In the encephalitic series as the age increased, the number of positive neutralization tests to both strains increased and there were more positives to a single type of virus alone among the younger groups than among the older. The predominance of positive tests for the St. Louis virus was among the older people, while that for the equine was among the younger.

11. No very definite relationship was noted between cases of the equine disease in horses and those in man, since the former did not reach epidemic proportions of those showing clinical symptoms and the observed cases were only occasionally in concurrent areas. Swampy lands and many mosquitoes, however, were in close association with the districts affected.

12. From the epidemiological evidence it seems likely that the equine virus was transmitted to man through some vector.

13. The St. Louis strain was brought in because of the migrant labor population.

CONCLUSION

The western virus of equine encephalomyelitis has been found capable of infecting man in certain districts of northern and central California and neutralizing substances for this strain have been found in the sera of 32 (37.0 per cent) out of 86 encephalitic cases diagnosed in 1937 and 1938. Forty-nine (47.5 per cent) out of 103 sera of this group gave positive protection tests for the virus of St. Louis encephalitis.

Detection of *Trichinella* Infestation in Hogs by the Intradermal Test*

ABRAHAM LICHTERMAN, PHAR.D., F.A.P.H.A., AND
IRVING KLEEMAN

Bureau of Food and Drugs, Department of Health, New York, N. Y.

THE work of recent years has shown that in the United States human infestation with *Trichinella spiralis* is much more common than was heretofore believed. Thus, 11 investigators¹⁻¹¹ whose papers have been published since 1930, report a total of 5,941 human cadavers examined, of which 935 were infested with trichinella, an incidence of 15.7 per cent. The control of trichinella infestation is therefore a subject which should interest the health officer.

It has long been recognized that the routine microscopic examinations of pork flesh, such as are carried on in various European countries, are quite unreliable, failing in many instances to reveal an existing infestation. Bachman,¹² in 1928, called attention to a useful precipitin test, and in a later article in the same year described a clearly defined, delayed type of skin reaction in rabbits and guinea pigs artificially infected with trichinella. Some time afterward, Augustine and Theiler¹³ began a well planned study of both the precipitin and the skin tests, applying them not only to swine but also to humans. In general, they followed Bachman's technic for preparing the antigen for the intradermal test. They also emphasized the immediate

character of the skin reaction obtained.

The present study was made to determine the value and accuracy of the intradermal test in detecting trichinous animals in a group of city-owned, garbage-fed hogs.

ANTIGEN PREPARATION

Albino rats weighing between 100 and 125 grams were starved 24 hours and then fed about 5 gm. of cheese which contained approximately 100 trichina larvae per gm. After 6 weeks, the animals were killed, skinned, and eviscerated. The carcasses were ground and then set aside for digestion in a fluid made by dissolving 5 gm. of pepsin in a liter of warm tap water and adding 7 cc. of concentrated hydrochloric acid. For every 50 gm. of meat, 2 l. of digestive fluid were used.

The apparatus and method for the digestion were similar to those used by Bozicevich.¹⁴ A 4 l. funnel, to the stem of which a centrifuge tube was attached by a short piece of rubber tubing, was used. A pinchcock was placed at the end of this tubing to permit closing, and the centrifuge tube containing larvae was removed after digestion of the meat. A crossbar, made by tying together two pieces of glass tubing, was placed in the funnel, and over this were laid 4 layers of cheesecloth. The digestive fluid was poured into the funnel and the meat carefully placed on top of the cheese-

* To be read before the Food and Nutrition Section of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 17, 1939.

cloth. The funnel was put in an incubator at 38° C. for 18 hours, at the end of which, the trichinae which had been liberated from their cysts by the digestive fluid had gravitated to the bottom of the centrifuge tube. The pinchcock on the rubber tubing was then closed and the centrifuge tube removed. The supernatant fluid along with the layer of sediment was removed by means of a pipette.

To remove some of the débris which had settled with the larvae at the bottom of the centrifuge tube, a 250 cc. funnel was set up in a manner similar to the one described above, the only difference being that no crossbar was used to support the cheesecloth. About 200 cc. of warm tap water was poured into the funnel and into this the contents of the centrifuge tube containing the trichina larvae mixed with some débris was washed.

In about 30 minutes, all of the larvae almost free of visible contamination had passed through the gauze and settled to the bottom. The rubber tubing was closed with the pinchcock and the centrifuge tube removed. The supernatant fluid was removed by a pipette and the larvae were washed several times with 0.5 per cent sodium bicarbonate solution. After each washing, the tube was set aside for 30 minutes, during which the larvae settled to the bottom and the supernatant fluid was removed.

At the third washing, a biuret test was performed on the supernatant fluid and found to be negative. Therefore, no further washings were done and the larvae were placed in an agate mortar and put into a vacuum desiccator containing phosphorous pentoxide. After evacuation of the air, the desiccator was placed in the refrigerator for 24 hours. The trichinae were then pulverized, weighed, and the powder extracted with 0.85 per cent sodium chloride solution, using 1:500 dilution.

After extraction for 2 hours at room temperature, the suspension was placed in the ice box for 3 days, at the end of which time the suspension was placed in a water bath at 58° F. for 1 hour on 3 successive days.

A portion of this suspension was then centrifuged at 3,000 revolutions per minute for 20 minutes. The supernatant fluid constituted the antigen used in our test. Prior to injecting the pigs, the antigen was standardized with the aid of artificially infested rats. The rats were divided into two groups of 12 each. The first group was injected with 0.1 cc. of the uncentrifuged antigen, using 3 rats each for dilutions of 1:500, 1:2,500, 1:5,000, and 1:10,000. This was repeated on the second group of 12 rats with centrifuged antigen. With the exception of the 1:500 concentration, Coca's solution (sodium chloride 0.7 per cent, sodium bicarbonate 0.05 per cent, phenol 0.4 per cent) served as the diluent and was also used for the control injection. Physiological saline was used in the control injection for the rats which received the 1:500 dilution of antigen. In all 24 rats, each dilution gave immediate type positive reactions, with wheals which at the end of 20 minutes averaged about 2.0 cm. in diameter. This indicates that the active principles are apparently in the supernatant eluted portion. It was this portion that was used for the intradermal skin test of hogs.

TESTING THE PIGS

The great majority of pigs used were of the graded Chester White and graded Yorkshire White breeds with several animals of the Poland China variety. The hogs were fed with uncooked swill. The garbage often contained considerable quantities of frankfurters, smoked sausages, bologna-style sausages, smoked ham, and other pork products. On no occasion was the garbage sterilized

23, 34	Positive	Positive *	Normal
46	Positive	Positive ‡	Normal
48	Positive	Positive †	Normal
4A	Positive	Negative	Wide area of erythema
5A, 6A, 15A	Positive	Positive *	Normal
7A	Positive	Negative	Papillary dermatitis of the skin
26A	Negative	Positive (very light infestation)	Heavy thickening of the epidermis
35A	Negative	Negative	Scaly dermatitis
NOTE: 44 pigs	Negative	Negative	Normal

* Light Infestation (1 to 10 larvae per gm.)

† Moderate Infestation (11 to 25 larvae per gm.)

‡ Heavy Infestation (26 or more larvae per gm.)

before being fed to the swine. The pigs averaged about 1 year of age before slaughter and in almost all cases, were killed 1 to 5 days after they were injected. The skin test was performed on the inner surface of the distal tibial region. The hair was removed with a clipper from a $2\frac{1}{2}$ sq. in. area, the surface washed with alcohol, and 0.1 cc. of the antigen was injected. The control injection of Coca's solution was given approximately 4 cm. from the site of the injected antigen.

In Tables I and II, we list only those pigs which showed deviations from the normal. The antigen used in the series shown in Table I was diluted with Coca's solution to a 1:10,000 dilution. Readings of the injected site were usually made in from 20 to 45 minutes. The wheal which forms is 1.5 to 2.5 cm. in diameter, and assumes a faint purplish-red hue with definite margins, without any noticeable erythema or edema of the surrounding tissues. Usually at the time of the reading, the bleb first formed by the control injection had almost disappeared.

In order to determine whether the skin diagnosis was correct, the dia-

phragms of the hogs were removed at the time of slaughter and digested as described in the preparation of the antigen, after removal of fat and grinding. For every 50 gm. of meat, 1 l. of digestive fluid was used. A convenient modification was the use of percolators of approximately 4 l. capacity instead of funnels in the digestion of the meat. The percolators were kept at 37° C. for 18 hours, at the end of which the attached centrifuge tubes were removed and examined for trichina larvae.

In the series shown in Table II, the antigen was diluted with 0.85 per cent saline containing 0.5 per cent phenol instead of Coca's solution, and this saline was used for the control injection.

Pigs 4A, 7A, 55, and 84, which gave positive reactions, showed no trichina larvae in the diaphragms. In pig 4A, there was an erythema of the entire clipped surface with a slight elevation 1 cm. in diameter. In pigs 7A, 55 and 84, there was a papillary dermatitis of the skin which, at the time of reading, showed a widespread erythematous area with several papillae. Pig 26A, which gave a negative skin test, showed 250 larvae in the diaphragm that

weighed 365 gm., or a very slight infestation. This pig had a marked epidermal thickening which was difficult to inject.

In pigs 85 to 179, no alcohol was used to wash the skin surface prior to the injection.

DISCUSSION

Altogether, 211 pigs were intradermally injected with trichinella antigen and skin readings were made within 20 to 45 minutes, the average being 30 minutes. Of these 25 were diagnosed

as positive and 186 as negative. Upon corroborative examination of the digested diaphragms, it was found that 21 out of 25 diagnosed as positive were trichinous, and 185 of the 186 diagnosed as negative were non-trichinous. Thus, 206 out of 211 pigs were correctly diagnosed, an accuracy of about 97 per cent. In this series, the incidence of trichinosis was 10.4 per cent.

It is advisable not to wash the skin surface with alcohol before injection of the antigen. This is especially important when a papillary dermatitis exists,

because of possible distension and erythema.

In pigs 85 to 179, where no alcohol was used, there were 16 pigs with papillary dermatitis, and in all the correct diagnosis was made. It is suggested, therefore, that pigs 7A, 55, and 84, with papillary dermatitis, may have been incorrectly diagnosed for this reason.

One pig, 26A, passed by the skin test as not trichinous, was found at autopsy to be infected. This pig had marked epidermal thickening, and was difficult to inject. In such cases, there is a possibility that the needle does not come into contact with the capillary circulation. Under these circumstances, no reaction will result even if the animal is trichinous. Pig 26A showed 250 larvae in a diaphragm weighing 365 grams. This is a very light infestation. It is important to remember that the intensity of the skin reaction bears no relation to the degree of infestation. In pig 111 the skin test gave a wheal, $2\frac{1}{2}$ cm. in diameter and well elevated in 25 minutes. From the digested diaphragm, only 4 larvae per gm. were obtained, denoting a light infestation. In this series of cases the small error in the skin tests was in the direction of safety, the test being more likely, now and then, to diagnose a normal pig as trichinous, than to permit a trichinous pig to pass as normal.

SUMMARY

Two hundred and eleven pigs were skin-tested with trichinella antigen. All the pigs had been fed on uncooked garbage. Post-mortem examination of the digested diaphragms was made as

a check on the diagnostic accuracy of the skin test. In 4 out of 25 pigs diagnosed as trichinous by skin tests, no evidence of infestation was found at autopsy; in 1 pig out of 186 diagnosed as non-trichinous, post-mortem examination showed trichinosis. Of 211 pigs skin-tested, 206 were correctly diagnosed as to the presence or absence of trichinous infestation. This is an error of less than 3 per cent. The error, moreover, is in the direction of safety, being more likely now and then to diagnose a normal animal as trichinous, than to pass a trichinous pig as normal.

Experimental Infection of *Dermacentor Andersoni* Stiles with the Virus of Lymphocytic Choriomeningitis*

H. J. SHAUGHNESSY, PH.D., AND ALBERT MILZER

Division of Laboratories, Illinois Department of Public Health, and Samuel Deutsch Serum Center, Michael Reese Hospital, Chicago, Ill.

ALTHOUGH only 4 years have elapsed since Armstrong and Lillie¹ showed that lymphocytic choriomeningitis is an infectious disease caused by a virus, the evidence indicates that the etiologic agent can be transmitted in several ways. Traub² has shown that the virus is discharged in the urine and nasal secretions of infected mice. Findlay and Stern³ succeeded in infecting 3 of 20 mice by nasal instillation of the virus. Finally Wooley, Armstrong, and Onstott⁴ have been able to transmit infection occasionally by instilling the virus into the urethra or vagina of monkeys. They have also demonstrated the virus in the seminal fluid and testicular tissue of infected animals. On the basis of these findings, together with the fact that antibodies against the virus were found by them more commonly in adults and especially in criminal and merchant seamen classes, these investi-

gators have suggested a venereal route of transmission.

However, the higher incidence of antibodies against this virus in criminals and merchant seamen may be accounted for by the greater opportunity for contact with infected mice and rats. Thus Findlay, Alcock, and Stern⁵ have isolated the virus of this disease from a patient who lived in an old house overrun with rats and mice. These authors intimate that they believe this may be a general source of infection.

Naturally infected mice have been found by Traub² and Lepine and Sautter.⁶ It is possible that other species of rodents such as ground squirrels and rats may also be naturally infected with lymphocytic choriomeningitis. Traub⁷ and Rivers and Scott⁸ noted that normal mice and guinea pigs are not readily infected by contact with infected animals, an observation which we have confirmed. The manner in which naturally infected mice contracted the disease is unknown. These findings suggested the possibility that blood sucking arthropods may be one means of transmitting the virus of this disease from rodent to rodent.

In the experiments reported here the

Rocky Mountain wood tick (*Derma-centor andersoni*, Stiles) was used as a convenient test vector. These were laboratory reared ticks obtained through the courtesy of Dr. R. R. Parker of the Rocky Mountain Laboratory of the U. S. Public Health Service and believed by him to be free from other infectious diseases. We noted no evidences of carriage of other diseases by the ticks during the course of our work, and control studies with uninfected ticks were always negative.

The strains of mice and guinea pigs used in our experiment were shown not to be naturally infected with lymphocytic choriomeningitis by subjecting them to intracerebral injection of starch, broth, or normal brain emulsion, procedures which have been found will activate latent infection with this virus into a typical syndrome.⁵ Our experimental animals were also tested for immunity resulting from possible previous subclinical infections by injecting large numbers intracerebrally with virus. No evidence of immunity was discovered.

Adult forms of the tick were fed by

confining them on the shaved bellies of guinea pigs under screw-top screen capsules such as described by Jellison and Philip.⁹ Since larvae and nymphs often become stuck to the adhesive tape girdle, it was necessary to use the technic described by Wolbach¹⁰ for feeding the immature stages. These forms were introduced into a covered jar containing the guinea pig on which they were to feed. The inner surface of the jar near the top was coated with vaseline to keep them from escaping. At the end of three days the guinea pig with attached ticks was transferred to a similar jar and the first jar steamed to kill unattached ticks. The animal remained in the second jar until the engorged nymphs or larvae had dropped. The latter were then collected and transferred to test tubes for further studies.

Rivers and Scott⁸ stated that the blood of guinea pigs inoculated intracerebrally is infectious for mice as early as the 4th day after inoculation. We have been able in three experiments to show that, following combined intracerebral and subcutaneous inoculation

of the W. E. 9,210 strain of virus, active virus appears in the blood stream of infected guinea pigs as early as 24 hours after inoculation and persists until the death of these animals. Sample protocols are outlined in Tables I and II. Virus in sufficient quantities to infect mice appeared in the blood stream of guinea pigs 48 hours after rubbing virus on their lightly scarified skins. The scarification was not deep enough to draw blood. From these studies it appeared that feeding ticks might become infected at any time from one day after infection until death.

Preliminary experiments in which ticks were collected after feeding on infected animals, ground up, and injected into normal animals indicated that larvae, nymphs, and adults, both male and female, can be experimentally infected in this manner. Infection persisted in adult ticks for at least as long as 13 days. Stage to stage transmission of the virus in ticks was also demonstrated by injecting ticks which had engorged in their previous stages on infected guinea pigs. The eggs of adult females which had engorged on infected guinea pigs also

** The control mice were inoculated with heart's blood drawn just before injecting guinea pig 3436 with the virus.

contained sufficient virus to kill guinea pigs injected with them. In one experiment the virus was shown to persist from infected adult ticks through their eggs and to the larval stage. It is of interest that the ticks which had engorged in their previous stage on an infected animal were apparently not infectious until they had engorged on a normal guinea pig. This parallels the phenomenon which occurs in Rocky Mountain spotted fever.

Although adult ticks probably would not migrate under natural conditions from animal to animal after they had once begun to feed, transmission experiments were carried on with them as well as with larvae and nymphs. In order to rule out the possibility of an extrinsic incubation period of the virus in the ticks, varying periods of time were allowed to elapse before transferring ticks from infected guinea pigs to normal animals as shown in Table III. All of the guinea pigs upon which the infected ticks were fed continued to gain weight in a normal manner, and none of them showed any significant temperature rise or other symptoms of

the disease during the 28 days that they were observed. Three weeks after the infected ticks were removed, the guinea pigs were tested for immunity by subcutaneous inoculation of virus to which all succumbed with typical signs of lymphocytic choriomeningitis.

Similarly all attempts to transmit the virus by feeding adults which had engorged in their nymphal stage failed. In our earlier experiments we encountered failure in attempting to transmit the virus by feeding nymphs which had engorged in their larval stage on infected animals. Since these findings were first reported, however, experiments have been completed showing that nymphs, which had engorged in their larval stages on an infected guinea pig, successfully transmitted the virus of lymphocytic choriomeningitis to normal guinea pigs by feeding on them. It is probable that our earlier failures to transmit infection in this manner were due to attachment of an inadequate number of infected nymphs to the test animal. In a personal communication Dr. Parker states that some batches of ticks fail to feed well.

* Six infected nymphs were included in this lot.

† Seven unfed nymphs were included in this lot.

Another possibility of natural transmission remained. In relapsing fever and plague it is believed that infection is acquired mainly by rubbing the infected dejecta of the lice or fleas into the wound by scratching the bitten area. Since we had already demonstrated that virus could penetrate the lightly scarified skin, this possible route of transmission was investigated. Feces from feeding adult ticks which had engorged in their previous stage were found to be infective when applied to a small area (about 3 x 3 sq. cm.) of skin scarified too lightly to draw blood. It was also found that crushed adult ticks applied to scarified skin caused typical symptoms of the disease in guinea pigs. Control experiments with normal tick feces and crushed ticks were uniformly negative.

SAMPLE PROTOCOL

Application of Infected Adult Tick Feces to the Lightly Scarified Skin of Normal Guinea Pig:

I. Control—

April 8, 1939, sufficient feces were collected from 8 adult female and 6 adult male ticks engorging on infected guinea pig 4006, 8 days after the ticks had attached, to prepare a 10 per cent suspension in buffered saline. Guinea pig 4012 was inoculated subcutaneously (1 cc.) with infected tick feces suspension. *Micrococcus epidermidis* and hay bacilli were isolated from the infected tick feces suspension.

Temperature record of guinea pig 4012: April 8, 101.7 (normal temperature before injecting tick feces); April 9, 101.6; April 10, 104.2; April 11, 104.8; April 12, 103.9; April 13, 101.5 (labored breathing); April 14, animal found dead. This animal lost 32 grams in 7 days.

At autopsy the brain was very hyperemic, and the other organs were apparently negative. No bacteria were isolated from the brain tissue. A 10 per cent brain suspension was then prepared and injected subcutaneously (2 cc.) into guinea pig 4015 and intracerebrally (0.03 cc.) into each of 2 white mice (cage 1A). Both of the mice developed typical signs of lymphocytic choriomeningitis in 8 days but recovered. Twenty-seven days after the first inoculation both mice and 2

controls were inoculated intracerebrally (0.03 cc.) with a 10 per cent suspension of infected guinea pig brain. The mice were immune to the virus because they remained normal during the 30 days that they were observed, while the 2 control mice succumbed in 7 and 10 days respectively. Guinea pig 4015 developed typical signs of lymphocytic choriomeningitis and succumbed in 9 days. No bacteria were isolated from the brain tissue of guinea pig 4015.

II. Tick feces applied to the lightly scarified skin—

April 8, 1939, the same 10 per cent suspension of infected tick feces was also applied to the lightly scarified skin of guinea pig 4014 with a cotton swab. Scarification was accomplished by making 8 scratches in the shaven skin not deep enough to draw blood by means of a razor.

Temperature record of guinea pig 4014: April 8, 102.5. (normal temperature before applying tick feces); April 9, 102 (scratches not visible); April 10, 102.2; April 11, 104.8; April 12, 104.2; April 13, 105.5; April 14, 104.5; April 15, 106.6; April 16, 104.7; April 17, 103.2; April 18, 101.9; April 19, 98.1 (labored breathing); April 20, animal found dead. In 11 days this animal lost 68 grams.

At autopsy the brain was inflamed, and there was a diffuse bronchopneumonia in the lungs. Other organs were negative. No bacteria were isolated from the brain tissue. A 10 per cent brain suspension was then prepared and injected subcutaneously (2 cc) into guinea pig 4017 and intracerebrally (0.03 cc.) into each of 2 mice (cage 3). Both of the mice developed typical signs of lymphocytic choriomeningitis and succumbed in 7 and 9 days respectively. Guinea pig 4017 also developed typical signs of lymphocytic choriomeningitis and succumbed in 12 days. No bacteria were isolated from the brain tissue of guinea pig 4017.

In the successful transmission experiments typical symptoms were produced in all test animals and all animals that died showed typical pathology. Surviving animals in all experiments were shown to be immune to inoculation of the virus of lymphocytic choriomeningitis. As a final proof, the virus was shown to be present in the test animals by inoculation of a guinea pig and several white mice as shown in Figure I. In all experiments bacteriologic studies, conducted aerobically and an-

FIGURE I

aerobically, indicated that only chance contaminants were present occasionally. Inoculation of animals with cultures of these organisms proved them to be non-pathogenic.

CONCLUSIONS

Experimental infection of all stages in the life cycle of the Rocky Mountain wood tick with the virus of lymphocytic choriomeningitis has been demonstrated. Stage to stage transmission of the virus from larvae to nymphs, nymphs to adults, and generation to generation transmission from adults to eggs and larvae has also been shown to occur. Attempts to transmit the infection by feeding adults on normal animals after previously feeding them in either their nymphal or adult stages on infected guinea pigs were uniformly negative. Infection has been transmitted, however, by feeding nymphs which had engorged in their larval stage on an infected guinea pig. Infection has also been transmitted by applying infected crushed ticks or feces from ticks which

had engorged in their previous stage upon infected animals to the scarified skin of guinea pigs.

It is suggested that other blood-sucking arthropods such as culicine mosquitoes, stable flies, and body lice may experimentally transmit the virus of lymphocytic choriomeningitis from rodent to rodent and possibly to man. If infection is transmitted from rodent to man, it is possible that this may occur by means of infected secretions or excretions such as may take place in febrile jaundice rather than by the bite of an arthropod.

The Physician's and the Nurse's Part in Health Education^{*}

DOROTHY NYSWANDER, PH.D., AND
MAYHEW DERRYBERRY, PH.D., F.A.P.H.A.

*Director of School Health Study, Department of Health, New
York, N. Y.; and Senior Public Health Statistician, U. S.
Public Health Service, Washington, D. C.*

HEALTH education has been claimed to be one of the major functions of each professional group engaged in the school health program. The physicians contend that they should do health education because they know the subject matter; the teachers claim that health education is their function because they know the method; the nurses maintain that they are the logical ones to teach health because, in addition to knowing sufficient subject matter and to having acquired some technics of presentation, they know their families and are in intimate contact with them. Implied in all these contentions is the concept that health education is primarily a matter of instructing parents and children on health subjects. The idea seems to be that if the proper professional worker gives instruction to those needing it, desirable results are assured. But the bare statement of the spoken or written word is not the sole means of bringing about the changes in attitude and behavior which we are trying to effect through our health education. *How* a statement is spoken or

written may have far more significance for the person addressed than actually *what* is said. Actions, too, often confound the words accompanying the action so that the individual may learn something altogether different from what was intended.

So instead of discussing the controversial question of whether health teaching should be done by the physician, by the nurse, or by the teacher, we have chosen to focus attention on the educational possibilities that are inherent in many of the administrative procedures and policies that are part and parcel of our school health programs.

As a background for this discussion it might be well to recall some of the factors with which all of us are familiar that influence *what* and *how* people learn. First, one seldom learns just one thing from even a single experience. Ordinarily a number of things are learned from the same situation. A child not only learns that his skin infection is impetigo when the doctor or nurse examines it and gives him the information; but depending upon the way he is told and the circumstances under which he is told, he may learn that accidental infections occur which do not reflect upon his

^{*} Read at a Joint Session of the American School Health Association and the Child Hygiene Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

home life, and that the doctor and nurse are his friends, that they will protect him from embarrassment in the presence of his friends and classmates, and that they will help him to get well. On the other hand, he may learn that the physician and nurse have no concern for his feelings, for they do not hesitate to tell him in the presence of other children that the infection is associated with dirt, or that he is unfit to be with his friends; he may even get the implication from conversations that he overhears in the medical room between doctor, nurse, and teacher that his home is responsible for his condition. Thus in the latter case he learns to fear the medical room and to resent these people who attack his fortress of inner security—his home.

Children and adults, who after all follow very much the same principles in learning, undergo at least three definite forms of change in each learning situation: (a) They learn the words that were spoken. (b) They learn to react emotionally to the way the total situation was handled. (c) They learn what action to take in the future to obtain any satisfactions that were present or what to do to avoid any unpleasantness that was inherent in the situation. Thus a wealth of attitudes, biases, hates, fears and prejudices are developed in every individual, and these are often found to have their origin in situations where the obvious intention of the teaching was far different.

Corollary to this principle is the fact that it is not necessary that something be done to or for an individual in order that he may learn. He frequently learns when we as teachers think we have done nothing to or for him. This is particularly true with reference to the development of attitudes. Providing a comfortable, quiet place where a mother may sit to discuss the health problems of her child

with the doctor, conserving the mother's time through carefully planned appointment systems, etc., are examples of situations in which parents learn to appreciate the school health services, whereas failures to keep appointments with parents or children, advising them to go to clinics where the waiting list cannot possibly admit another person, and giving a medical examination without an explanation to the parent of what was or was not found are very likely to develop in the parents and children negative attitudes that often seem irrational to the staff.

In the light of the certainty with which learning other than that specifically intended takes place in various situations, let us examine some of the school health procedures to discover the possibilities for both positive and negative education that they present.

First of all, the initial as well as every contact of a parent or child with the physician and nurse is fraught with educational possibilities. Usually the first contact of the parent with a physician or nurse is a note either requesting the parent to take his child to a physician for an examination or inviting him to be present at the school examination of the child. Do physicians and nurses analyze such messages sent to the home to see that they accomplish the real objectives of the school health service? Is the manner in which the note is sent and the wording of it such that the parents are convinced that the request is made because the school has a vital interest in the child's health, or do the parents learn from the note that the school health service is merely carrying out a routine service without much thought as to the circumstances governing the lives of the family?

To make the point more concrete consider the following extreme example which is an actual case. "Come to

school at 9 A.M. to see me" signed "School Nurse" was hurriedly written on a scrap of paper left undated, folded, given to a boy with the command "Take that home to Mother." If such a note survives the usual vicissitudes of messages given to little boys and reaches its destination, is it likely to start a chain of events in which the parent will understand that a specific problem is to be discussed with her, will she keep the appointment with the nurse, and expect professional guidance which she may trust?

Consideration for the way in which notes are worded, who sends them home, and the method of sending them, has been experimentally shown by the New York City Study to influence the response which is obtained. One type of note resulted in a 30 per cent response from the parents. A more carefully planned note caused 85 per cent to respond to the message sent home.

The next most common experience of the parent and child with the school health service from which much positive or negative health education takes place is the visit to the medical room to see the doctor or nurse. Even the room itself can affect the parents' and children's attitudes toward, and conceptions of the school health service. If the medical quarters are clean, well lighted, well ventilated, if they have adequate room for all those who are visiting it at one time, and if there are sufficient chairs for those who must wait for short periods, other things being equal, favorable attitudes toward the health work of the school will be developed. But if, as so often happens, the physician and nurse must work in a niche in a corner, or in an empty classroom vacated because of its lack of light, the unlikely stage set will not promote a confidence in medical service or build a respect for the confidential trustworthy relationships be-

tween patient and physician which we claim we are trying to build up.

Although the physical lay-out of the medical quarters and the comforts or inconveniences that the child and parent experience while waiting in them have important influence on learning, the treatment accorded them by the doctor and nurse during the examination and accompanying interview is far more potent in determining what they learn. Are they greeted courteously? Are explanations made carefully if unexpected delays occur? Is the mother made to feel that her presence is not only welcome, but important? These are the factors that build attitudes. This, of course, is no new thought, for all school health workers have stressed the possibilities for educating both parent and child at the time of the medical examination. But in our observations of some of the examinations in various school systems, we have been led to wonder if the possibilities for learning the wrong attitudes and the wrong health behaviors from our routine procedures have been fully recognized.

Do we always recognize that the things we do not tell the parent but which are implied by our actions, lead him to form many erroneous convictions and may bring about negative attitudes toward the school health service? Perhaps an extreme situation will emphasize this point. Consider the mother who observes the examination with a stethoscope of the chest of her only child. The doctor listens—he listens again—he frowns—listens again. He has the child lie down on a couch, and listens several times, shakes his head, then listens a second time with the child standing. The mother suspecting something anxiously asks "What is the matter, Doctor?" Not wishing, without a cardiograph and more adequate examination to make a diagnosis of the heart murmur he has

heard, the doctor answers, "The nurse will tell you what to do." The nurse according to the prescribed policy gives the mother a printed slip and says in a routine fashion, "Take this slip with you and take John to your private physician. Don't worry about it." The mother looks at the slip. On it is written "cardiac" with a question mark after it.

Now more concerned than ever, having no family physician and having received no instruction in the selection of one, the mother finds a doctor's sign on the way home and decides to take Johnny there that night. The doctor after no more careful examination than was given at the school tells her that Johnny has a little heart murmur but it amounts to nothing. He further tells her that the school should have told her that it was nothing at the time.

Now what did that mother learn? First of all she learned that the school physician did not tell her all he knew. She also learned that the private physician had little respect for the school physician and the way he handled the situation. She learned to pay little attention to the advice and instruction from the school medical service. She may have learned that the school health service made her spend money for an examination that she would not have spent if she had not come in contact with it. Nor did she have the positive learning experience of finding out what a good cardiac examination is like. On the other hand, she went through an experience with considerable negative emotional content and will no doubt tell it over and over to other mothers who have children in school. Thus she becomes a negative agent of health education not because of instruction that was given her but because the school doctor in examining her child followed prescribed medical technics, but overlooked the effect of

those technics on the personalities with which he was dealing.

In recounting this incident we are aware of the pressure placed upon physicians and nurses to examine a large number of children within a very short time. We are also aware of the many restrictions that policies place upon them with reference to usurping the functions of the private physicians. However, we have given the incident in the extreme to show how negative health education may result if proper consideration is not given to the attitudes and ideas that are outcomes of the procedures which we use.

If the parent has not been present at the examination and some condition needing medical attention has been found, opportunities for negative or positive education occur in the follow-up procedures. The methods used may include a note to the parent, a home visit by the nurse, a consultation in school, or contacting the child in school. Whatever the procedure, the information given should be positive and backed by sufficient reason to convince the parent that medical care is needed. All of you are familiar with the situations frequently arising during the follow-up, when the private physician or clinic disagrees with the findings of the school physician. It is recognized that disagreements in diagnosis are sure to arise, but do we consider what such disagreements teach the families with which we are working? Too often we concern ourselves only with the administrative relationships which hamper our work, and fail to recognize the effect of such situations on those who are the objects of our endeavor.

The description of these difficulties by no means suggests the solution. It does, however, point out the possibilities for negative education presented by the school health service, and what may be learned as a result of some of the

administrative procedures and policies under which the school physician and nurse must work. Although we are not in a position to suggest the proper procedures, it is our conviction that administrative policies and procedures should be influenced far more by the ideas and attitudes they engender in the parents and children than by immediate administrative exigencies of the situation.

In summary, then, there are many situations in the school health program involving the physician and the nurse that abound with teaching possibilities. If in these situations the procedures followed by the physicians and nurses bring pleasant experiences to the parents and children and satisfy their

wants and needs, much good health education will result; favorable attitudes toward proper attention for the immediate health problem as well as toward the future use of medical care will be built up. If, on the other hand, the school health procedures are carried on in a routine and regulatory fashion without regard to the feelings, the wants, the comfort, and the understanding of both parents and children, much negative learning is likely to take place. Therefore, one of the contributions of the physician and the nurse to health education is to make sure that all of their procedures and methods result in positive rather than negative learning on the part of their clientele.

Bacteriological Tests on Mechanical Dishwashers for Home Use

WALTER E. WARD, PH.D., AND G. M. DACK, PH.D., M.D.

Department of Bacteriology and Parasitology, University of Chicago, Chicago, Ill.

MUCH attention has been given to the public health aspects of dishwashing in large establishments whereas comparatively little attention has been given the domestic problem. Since mechanical dishwashers designed for domestic purposes are now coming into use, it is necessary, for an evaluation from the public health standpoint, that scientific information be obtained concerning their effectiveness in removing bacteria from soiled dishes. Therefore, the purpose of this investigation was to determine, under controlled laboratory conditions, the amount of bacterial residue remaining on dishes after washing in two domestic dishwashers.

Machine A, the smaller, opened from the front and contained a sliding rack for holding the dishes in position during the washing procedure. Machine B opened by a hinged top and contained a double rack for utensils. Both machines had fully enameled one piece tubs with drains operated by exterior control knobs. An impeller, electrically driven, was used in both machines to throw the water across the surfaces of the dishes and remove the food soil. Water at 150° F. (65.6° C.) entered the machines through a spray mechanism situated above the dasher. Machine A held 5 quarts of water and B held 4 quarts of water during the wash period. Detergents compounded without soaps were used in the washing procedures.

METHODS

Dishes were soiled with several types of food to simulate natural conditions. Soft boiled eggs (thoroughly minced), melted Crisco and cooked Farina were used. Suspensions of the test bacterium were added to these materials, a thorough mixing performed, and the resulting mixtures spread on the top surfaces of the dishes in a layer as nearly uniform as possible. The egg and Crisco soils were dried on the dishes for 30 minutes before washing. Dishes soiled with Farina were washed immediately after contamination. Glasses, cups, and silverware were soiled with a neutralized nucin suspension of bacteria. This material was likewise allowed to dry for 30 minutes before washing.

Calgonite (an alkaline material containing sodium hydroxide, trisodium phosphate, sodium metasilicate, and sodium hexametaphosphate) and trisodium phosphate were the detergents tested in the machines. The standard washing procedure consisted of: (1) a preliminary 10 second spray rinse with the drain open, (2) a 5 minute wash with the drain closed, (3) a 10 second spray rinse with the drain open, (4) a ½ minute rinse with the drain closed (first rinse), (5) a 10 second spray rinse with the drain open, (6) a final rinse of 1 minute with the drain closed (second rinse). At the end of this period the dishes were allowed to cool

for a few minutes before examination was begun.

Examination of the utensils was accomplished by a swabbing process. The entire front surface of all dishes such as plates, and the parts of glasses, cups and silverware normally coming into contact with the food or mouth were tested. Swabs, made up on applicator sticks, were sterilized in nutrient broth tubes (5 cc. per tube) and washed off in this broth after use. A portion of the latter was plated into suitable media to allow a count to be made. In some instances dishes in various portions of the machines were replaced with glass discs. After the soiling and

washing procedures these discs were placed in large Petri dishes and washed off with melted agar. This gave an insight into the efficiency of the swabbing procedures. Veal infusion agar was used to test for *Eberthella typhosus* and *Staphylococcus aureus* while blood agar was used for streptococci. In testing for *Mycobacterium tuberculosis*, inoculations were made subcutaneously into the groin of guinea pigs. All plates were incubated at 37°C. for 48 hours.

* Sterile dishes were introduced into machine with soiled dishes.
— indicates no tests made.

been added, was put on sterile dishes and the latter washed in the machines. Glasses, cups, and silverware were not soiled at this time, but they, along with other dishes, were tested by the swab method at the end of the wash period. This was done to determine the amount of transfer that occurred from the contaminated to the sterile dishes. Tests were also made to determine the efficiency of the wash and rinse procedures. In such tests the dishes were swabbed at the conclusion of the 5 minute wash period, after which the experiment was begun anew, and tests made at the end of the first and second rinses in a similar fashion. As would be expected the first rinse is quite effective in removing contaminating organisms. Calgonite, in 0.3 per cent concentration by weight, was used in obtaining the results tabulated in Table I. The heading, "Sterile Dishes," in that table is used to indicate glasses and cups that were put into the washer in a sterile condition along with the soiled dishes.

In those experiments in which glass discs were substituted for dishes, the results showed the swab method to be approximately 50 per cent efficient in recovering organisms from contaminated surfaces when only small numbers were involved. Thus, those dishes listed as "Sterile" in Table I and subsequent tables may or may not be in this condition. However, the majority

of the results in the literature are based upon a swab method of recovery. These data are in agreement with those of Fellers, Levine, and Harvey.¹

Staphylococcus aureus withstood the washing procedure better than either *Streptococcus pyogenes* or *Eberthella typhosa*. According to Devereux and Mallman,² Calgonite is quite effective as a germicide against *Escherichia coli* but it has little or no effect on *Staphylococcus aureus*. Our results support this observation. When bactericidal tests were made at 140° F. (60° C.) by *in vitro* methods, the effect of heat overshadowed any possible effect of the detergent and all organisms of the three types tested were killed in from 5 to 7 minutes. Varying the degree of hardness of the water with either detergent gave no alteration of these results. However, in both the A and B machines the water was cooled to such an extent by the dishes that only the second rinse water in machine A reached 141.8° F. (61° C.), while that in the larger machine B only reached 135° F. (57.2° C.). Tests made at a temperature of 122° F. (50° C.) showed viable organisms present at the end of 10 minutes.

When trisodium phosphate was substituted for Calgonite and a large number of washings made over a period of time, with no sterilization of the machine or dishes during such a period, a noticeable film formed on the

TABLE II

Viable Bacteria on Cups, Glasses, and Silverware Soiled with a Neutralized Mucin Suspension of Staphylococcus aureus and Washed by the Standard Procedure in Machines A and B

Spoon	83	80	6	4	8	8

utensils. This was especially noticeable on the glasses. Bacteriological methods in which the film was completely broken up did not show that there was any noticeable accumulation of bacteria as has been reported by Hall,³ Hall and Schwartz,⁴ and Cox.⁵ These workers were not concerned with a specific bacterium of a pathogenic type, so it is entirely possible that other types of bacteria normal to air, water, etc., would accumulate in such a film. It is doubtful, though whether they would be capable of growing in a film of this type. Recently, Hall⁶ reported on the use of a milk culture of *Staphylococcus aureus* as a soiling agent. The dishes were washed with a trisodium phosphate detergent and the film was definitely found to contain bacteria. However, to quote from Halvorson, Bayliss, Ordall, and Wilson⁷: "The type and extent of the deposits formed depends upon the water hardness and temperature, the type of soil, the nature of the surface being cleaned, the soap and buffers used, the washing procedure, and other such factors."

In order to gain an idea as to the relative efficiency of the machines in contrast to hand washing procedures, dishes were soiled with bacteria-food mixtures and washed by hand, using a common brand of flake soap. The wash and rinse waters were adjusted to an initial temperature of 120° F. (48.9° C.). The swab method of testing was used. All the dishes remained contaminated, but to a varying extent. As an example, there was an average of 26 bacteria for each of the soiled dishes after rinsing and air drying in contrast to 11 when identical mixtures were used for soiling and the dishes washed in a machine. Sterile cups, run through the wash and rinse water, retained an average of 18 organisms in contrast to 7 when washed in a machine.

Cups, glasses, and silverware were soiled with *Staphylococcus aureus* suspensions in neutralized mucin and washed by the standard procedure using Calgonite (see Table II). In experiments of this type all other dishes were placed in the machines in a sterile condition so that the transfer from plates, etc., as previously shown in Table I, would be eliminated. The maximum number of bacteria per utensil was never greater than 24 when tested by the swab procedure. A large majority of the dishes appeared to be sterile.

In view of the possible dissemination of tubercle bacilli by contaminated utensils and considering the resistance of this organism, it was thought that results of some significance could be obtained by using such an organism in the food soil. The H37 strain of the human tubercle bacillus was grown on Lowenstein's medium, ground in a mortar with sterile reagent sand, and mixed with finely divided egg material. Dishes were soiled in the usual fashion. Tests were made of the preliminary spray rinse, of the main wash water, and of the dishes. In the latter tests 5 of one type of dish were swabbed with a single swab. The swab was rinsed in 4.0 cc. of sterile saline after each dish was examined. Guinea pigs were inoculated subcutaneously into the groin with the test material. The materials containing Calgonite were neutralized before being injected. Results are given in Table III.

From Table III it is apparent that the organism causing human tuberculosis can withstand the washing procedure and still be present in small numbers on eating utensils.

Although both machines had fully enameled one piece tubs, there were certain regions where accumulation of food soil and bacteria might occur. These regions were checked by a process of cumulative washing in

which dishes were washed several times daily for periods of 1 week with no sterilization or cleaning of the machine during the period. Egg soil containing *Staphylococcus aureus* was used in these tests. Machine A showed some accumulation beneath a door stop of rubber and around a perforated plate over the drain valve. In machine B the greatest and only accumulation of importance was on a portion of the groove in which the lid gasket rested. However, there was no evidence of bacterial growth or odors in the sections where accumulation occurred.

SUMMARY

Two mechanical dishwashers designed for domestic purposes were subjected to rigidly controlled tests for the removal of bacteria from dishes contaminated with food soils consisting of one of the following: egg, fat (Crisco), wheat cereal (Farina), and neutralized mucin. The food soils were inoculated with one of the following bacteria: *Staphylococcus aureus*, *Eberthella typhosa*, *Streptococcus pyogenes*, and *Mycobacterium tuberculosis*. For comparative purposes dishes similarly soiled were washed by hand in water to which a common brand of soap had been added.

Dishes washed in the two machines were not sterile but had fewer residual bacteria than those washed by a hand

procedure. The numbers of residual bacteria are apparently reduced by a mechanical washing-away action and not by the temperature of the water or any great germicidal effect of the detergents. According to Behrend,⁸ utensils yielding a count of from 1 to 10 bacteria may be classified as excellent, from 11 to 30 good, from 31 to 50 fair, from 51 to 100 poor, and more than 100 bad. On this basis the machines on the average, when used according to standard procedures, gave excellent results.

The ideal dishwasher from the public health standpoint is one which will remove all pathogenic microorganisms from dishes. At present certain technical difficulties interfere with the achievement of that goal.

Active Immunization Against Diphtheria

The Efficacy of Several Methods Used in a City of Medium Size

FRANK KIRBY HARDER, M.D., ABRAHAM GELPERIN, M.D.,
AND WALTER R. COOK, M.D.*

*Acting Commissioner of Health; District Physician; formerly
District Physician; Department of Health, Cincinnati, Ohio*

DURING the last five decades there has been a decline in the mortality from diphtheria. Figure I, beginning with the year 1870, shows Cincinnati's crude mortality in children under 10 years of age. A peak was reached in 1890.

Morbidity records are less accurate than mortality statistics, but the general trend of diphtheria morbidity in Cincinnati during the last three decades has been downward. There was an acceleration of this downward trend in 1928 and 1929 when the first local large scale immunization program was inaugurated. This result was encouraging although the decline was not greater than that which had occurred at previous times when active immunization had not been employed. Toxin antitoxin was the first antigen used. Sometimes 3 and sometimes 4 injections were given at intervals of 1 week. Two injections of formolized toxoid, 1 week apart were substituted in 1932. In 1934, the single injection of alum precipitated toxoid was given, and in 1936, this was changed to 2 injections of alum

precipitated toxoid at an interval of 4 weeks. Innovations in antigen and the number of injections have been introduced so rapidly that the merits of the various methods have not been completely evaluated.

Efforts should be made to determine accurately whether the decline in diphtheria has been produced by control measures or by unknown factors governing the natural cycles of the disease. Lucia and Welke¹ made a comparison between mortality trends in Providence, R. I., where there had been a vigorous campaign for immunization against diphtheria, and San Francisco, Calif., where there had not been such an active campaign. The trends in both cities were similar. Woods² showed that in England the decline in mortality from diphtheria was similar to that from scarlet fever although no large scale immunization measures against scarlet fever had been carried out. On the other hand, experience in institutions, Young and Cummings,³ in schools, Park,⁴ and in health districts, Gundel,⁵ indicates that active immunization has helped in reducing the incidence of diphtheria.

Diphtheria Mortality for Cincinnati, Ohio, Rates per 100,000 Under 10 Yrs. of Age - 1870 - 1937.

Figure I

EPIDEMIOLOGY OF DIPHTHERIA

Resident cases for the years 1932-1937, were studied. The population figures used were those obtained in a local census in the year 1935.

Distribution by Season, Sex and Age—In Cincinnati, the epidemiology of diphtheria has generally conformed to the usual pattern. The peak incidence has been reached in late autumn and early winter. In the earlier years of life, both sexes have been equally affected. In the few cases which have occurred after 20 years of age, there

has been the well known preponderance of the disease in females because of their close association with children. In relation to age, the greatest incidence of cases and deaths has been in the late preschool and early school years.

Distribution by Economic and Racial Groups—These two topics may be appropriately considered together. Cincinnati's area has been divided into 107 census tracts, and these in turn fall into 4 economic groups, based on average rentals. The populations of the 4 groups are approximately equal.

TABLE I

Distribution of Diphtheria in White and Colored in Relation to Economic Level

Economic Group	White			Colored		
	Population Under 20 Yrs. of Age in 1935	Total Resident Cases Under 20 Yrs. of Age in 1932-1937	Average Yearly Rate per 100,000 Under 20 Yrs. of Age	Population Under 20 Yrs. of Age in 1935	Total Resident Cases Under 20 Yrs. of Age in 1932-1937	Average Yearly Rate per 100,000 Under 20 Yrs. of Age
I (Lowest)	27,631	403	243	11,075	80	120
II	30,906	288	155	5,024	13	43

IV (Highest)	30,481	75	41	460	2	72 *

* Omitted in preparation of Figure II because of questionable validity.

Distribution of Diphtheria by Economic Groups - White and Colored.
Morbidity Rates per 100,000 under 20 years of age - Six Year Average.

(Colored Rates have not been shown for Groups III and IV because of questionable validity.)

Figure II

Group I is the lowest and Group IV is the highest in respect to economic well-being.

Table I and Figure II show that diphtheria like tuberculosis, is a disease associated with poverty. It is also indicated that the white race is more susceptible to diphtheria than the colored. A comparison of the total white and colored populations under 20 years of age would not have been valid because most of the colored population is in the lower economic groups.

The preponderance of diphtheria in economic Groups I and II cannot be attributed to neglect of inoculations. The Health Department and other agencies have provided free inoculations in these groups while Groups III and IV have been cared for by private physicians.

DIPHTHERIA DESPITE INOCULATION

Cases of diphtheria occur even in

those inoculated. The term inoculation rather than immunization is used for the reason that the latter implies that the desired result has been obtained. From the data available, it is impossible to tell which of the standard antigens has been most efficacious. Cases of diphtheria have occurred after the administration of all of them. Many occurred within a year after the administration of the antigen. The failure to prevent diphtheria in these instances, therefore, cannot be attributed to loss of immunity over a long period of time.

The fact that attempts to immunize against diphtheria sometimes fail is not of recent discovery. Park⁴ pointed out that even in children with negative Schick tests, naturally or artificially produced, the incidence of diphtheria was decreased but the disease was not entirely eliminated.

Do those who have contracted diph-

TABLE II

Cases Under 20 Years of Age in Which a Definitely Positive or Negative History of Previous Inoculation Could Be Obtained

	Cases	Deaths	Fatality Rate Per cent
Not Inoculated	474	22	4.64
Inoculated	238	11	4.62

theria despite inoculation have milder cases? Fatality rates in non-inoculated and inoculated children (under 20 years of age) are shown in Table II. The difference was not significant. The only cases considered were those in which it was possible to get a definite yes or no answer to the question concerning previous inoculation. All cases in inoculated children were considered in one group regardless of the antigen used because there were not enough cases to consider mortality in respect to each type of antigen. Cases developing within 6 weeks after completion of inoculation and cases in which the full course of inoculations had not been completed were considered as non-inoculated.

When diphtheria has developed in previously inoculated children, physicians have not delayed in giving antitoxin. The average interval between onset of sickness and administration of antitoxin was slightly shorter in inoculated than in non-inoculated children.

The incidence of diphtheria in inoculated and non-inoculated children of the same race and comparable economic levels could not be calculated because of lack of accurate data concerning the number and distribution of the inoculations. Of the cases of diphtheria in the 238 previously inoculated children 195 (81.9 per cent) were in the low economic groups, I and II. The distribution of the cases in inoculated children was similar to the general distribution where 784 (79.5 per cent) of the 986 cases in children were in the same low economic groups.

ARTIFICIAL AND NATURAL IMMUNITY AS MEASURED BY THE SCHICK TEST

It has been shown by Guthrie, Marshall, and Moss,⁶ Park,⁴ and others that the Shick test is a fairly reliable method of measuring immunity to diphtheria. Jensen⁷ and Brandon and Frazer⁸ have recently and more accurately determined the approximate level of blood antitoxin which is necessary for a negative Schick test.

As an individual goes through life, he has exposures to the diphtheria bacillus, frequently in the city, less frequently in rural areas. Active immunization should be carried out early in life in order that early exposures to the diphtheria bacillus may stimulate higher levels of immunity rather than produce the disease. The duration of artificial active immunity will depend to some extent upon the frequency of subclinical infections. Therefore, in comparing the duration of immunity conferred by various types of inoculations, strictly comparable groups must be studied. Rural and even suburban populations must not be compared with urban populations because the frequent subclinical infections in crowded areas produce a prolongation of artificial immunity that cannot be expected in more sparsely populated areas.

In this Shick test survey two neighboring suburbs, M. and E.E., were studied during the school year 1935-1936. Both suburbs were relatively homogenous areas, intermediate between rural and urban. A control group and groups of children who had received various numbers of injections of various antigens without preliminary Schick tests were used. The findings in the various groups were not exactly comparable because the intervals of time between the administration of the various antigens and testing were not always the same. Nevertheless, it was possible to reach certain conclusions. The results are given in Table III.

TABLE III

Schick Tests in a Relatively Homogenous Suburban Area—Groups of Children Who Had Received Various Numbers of Injections of Various Antigens and a Group Who Had Received None

	Children in Group	Schick Positive		Schick Negative		Interval between Inoculation and Schick Test in Years	Mean Age in Years at Time of Schick Test
		Number	Per cent	Number	Per cent		
Non-Inoculated (Controls)	544	359	66	185	34		11.22 \pm .09
Toxin-Antitoxin (4 Injections)	208	60	29	148	71	6	10.80 \pm .09
Toxin-Antitoxin (3 Injections)	735	253	34	482	66	4-7	10.93 \pm .08
Ramon Toxoid (2 Injections)	650	297	46	353	54	2-3	7.66 \pm .06
A. P. Toxoid (1 Injection)	219	45	21	174	79	1 or less	6.50 \pm .15
Total Tested	2,356						

Schick test readings which gave prolonged nonspecific reactions (about 5 per cent) were not included.

Each of the groups of inoculated children showed a definitely higher level of immunity than the control group. This was particularly significant because the controls were older and therefore had a higher level of natural immunity. The relatively good results in the group which received one injection of alum precipitated toxoid may have been due to the short interval of time between inoculation and testing. The somewhat poorer results in the group which received two injections of formalized toxoid may have been due to the younger age of the members of that group, or to the fact that they received only 2 injections 1 week apart. The results in the group which received toxin-antitoxin were relatively final and represented the resultant immunity status after primary stimulus and natural immunization had reacted over a substantial period of years. There was no significant difference between the immunity levels of those who received 3 injections of toxin-antitoxin and those who received 4.

DISCUSSION

No actively immunizing agent provides perfect protection against diphtheria. This is not surprising in view of the fact that the disease itself does not provide complete protection against subsequent attacks.

The results of this survey indicate that any one of the standard antigens properly given produces an immunity level higher than the level in similar controls. There is no clear-cut evidence that the immunity level produced by any particular antigen is higher or more lasting than that produced by the others. Much accurate data must be accumulated over a long period of years before the final answer concerning the best method can be given.

The findings of Wells, Graham, and Havens,⁹ Friedman,¹⁰ Graham, Murphree, and Gill,¹¹ and Saunders¹² confirm the opinion that inoculation with alum precipitated toxoid is the best single injection method of immunization. We have, therefore, continued its use, supplemented by a second injection. It is desirable to do as complete a job as possible with the first injection because indifferent and care-

less mothers sometimes fail to bring their babies back for subsequent treatments.

There are several reasons for giving a second injection of antigen. First, the reports of Bousfield¹³ cast doubt upon the efficacy of the single injection, even of alum precipitated toxoid. Second, the work of Pansing^{14, 15} indicated that the duration of immunity is longer in children who have received two injections of alum precipitated toxoid. This is particularly significant because Pansing has worked in a rural area where efforts to produce immunity have not been helped along by frequent subclinical infections. Third, the animal experiments of Glenny and Südmersen¹⁶ indicate the value of secondary stimulus. If their observations are to be extended to human beings, the interval between injections should be moderately long—at least 4 weeks.

Since May, 1936, we have been using two injections, 1 cc. each of alum precipitated toxoid at an interval of 4 weeks. This is essentially the procedure which Park¹⁷ has advocated. A few cases of diphtheria have developed even after this treatment, but it is too soon for an evaluation of the results. Schick tests on a little over 100 preschool children in suburb M, indicate that 90 per cent are Schick negative 3 months after the second injection of alum precipitated toxoid.

CONCLUSIONS

1. The morbidity and mortality from diphtheria are declining. Artificial immunization has probably accelerated these declines.

2. Several injections of antigen give better immunization than a single injection. In the case of toxin-antitoxin used in a suburban area there is a leveling off after 3 injections. Four injections do not give significantly better results.

3. Cases and deaths from diphtheria occur even after inoculation. So far,

there is no definite evidence that such cases are less severe than cases in non-inoculated children.

4. Diphtheria affects predominantly the children of poor white parents. In the control of the disease, the improvement of living and housing conditions is important.

Similarity of Chronic Infections With *Salmonella* Typhimurium and Tuberculosis in Guinea Pigs

EDWARD A. BIRGE, M.D.

State Laboratory of Hygiene, Medical School, Madison, Wis.

THE occurrence of *Salmonella* infections among guinea pigs has been recognized for many years. Smith and Stewart¹ first described the condition in the United States and gave it the name "pseudo-tuberculosis." The resemblance between this infection and that produced by tubercle bacilli is quite close as has been repeatedly emphasized. The condition has usually attracted attention, however, because of the increased mortality it produces in guinea pig herds rather than because of the confusion which may arise when such diseased animals are used for diagnostic purposes. In view of the increasing use of guinea pigs for the detection of subclinical and minimal tuberculosis in man, it appears desirable to point out the difficulties which may arise from this source.

"Pseudo-tuberculosis" occurs both as epizootics with, at times, an appalling mortality (Wherry,² Plague Commission,³ Petrie and O'Brien,⁴ Howell and Schultz,⁵ Gheorghii and Barth⁶), and as enzootics (Thomas,⁷ Edington,⁸ Duthie and Mitchell,⁹ Walker and Sweeney¹⁰). The transition of an epizootic into an enzootic has been described by Nelson and Smith¹¹⁻¹⁴ in a series of papers. The outbreak to be discussed by us was apparently an enzootic which was activated into an epizootic of mild degree.

In this laboratory approximately 50 guinea pigs are inoculated each week with material obtained from patients thought to have tuberculosis. These animals are 6-8 weeks old at the time of inoculation, and are supplied to us as they are required. They are placed in a single large pen when received. After injection, they are placed in individual cages in another room where they remain for 6 weeks, when they are killed and autopsied to determine whether they have developed any lesions of tuberculosis. Ordinarily, we expect about 6-8 per cent of the inoculated animals to die of intercurrent infection during the 6 weeks' observation. In the early part of August, 1938, following a severe heat wave, the mortality rose to 19 per cent. At first these deaths were attributed to the heat as no lesions could be found at autopsy. Shortly afterward we began to find an occasional animal which presented all the gross pathological changes seen in guinea pig tuberculosis of the artificial variety, but in which no acid-fast bacilli could be found in the routine smears made from the caseous lesions. Microscopic sections of the spleens showed a histological picture identical with that of tuberculosis. On more thorough bacteriological investigation we were able to demonstrate Gram-negative bacilli.

TECHNIC

Each guinea pig was opened with clean but not sterile instruments. Smears were made from any accumulation of fluid in either the abdominal or thoracic cavities. Cultures of the blood, urine, and bile were made with aseptic precautions into 1 per cent glucose broth. Several fecal pellets, were removed from the lower bowel, macerated in a 30 per cent glycerin-0.5 per cent lithium chloride mixture, and a heavy inoculation smeared over the surface of a Blair-Wilson bismuth sulfite medium plate. The spleen was removed, passed through a flame to sterilize the outer surface, and transferred to a sterile mortar, ground to a pulp, a thick emulsion made with sterile normal saline, and finally inoculated into 1 per cent glucose broth. All cultures were incubated for 48 hours and those showing growth were subcultured on a litmus-lactose agar plate to test the purity of the culture. Colonies from this plate were then inoculated into the various test sugars and agglutinated by a specific serum (strain 1 serum).

BACTERIOLOGY

One hundred and forty-eight animals were studied, 48 of which were found to be infected. Seventy-eight cultures were completely identified; 39 from the spleen, 25 from the feces, 9 from the blood, 3 from the urine, and 2 from the bile. All of these were identical culturally and serologically with the original culture isolated from a caseous abscess in a spleen and referred to in this paper as strain 1. This strain was used to immunize a rabbit to produce an immune serum with a titer of 1-10,000 for the homologous organism.

Cultures of the heart blood were always found to be positive in animals dying from the disease—either acute or chronic. In 4 animals killed, and found at autopsy to be suffering from the disease, blood cultures were nega-

tive. Urine and bile cultures were not made routinely, but the urine was found to be infected in 4 of 8 diseased animals, the bile in 2 out of 6. In 32 infected animals, cultures of both the spleen and feces were made; in 15 both were positive; in 13 the spleen was positive while the feces were negative; in 4 the feces were positive but the spleen negative. Whether these latter animals were passive carriers cannot be proved, but it is certainly suggestive.

Previous workers have shown that the infecting organism is either *Salmonella typhimurium* (Edington,⁸ Petrie and O'Brien,⁴ Nelson¹³), or *Salmonella enteritidis* (Duthie and Mitchell,⁹ Plague Commission,³ Thomas⁷). Much of the earlier work has to be discarded because of the recent advances in classifying members of this group. Wherry² reported an organism which he called *Bacillus pestis caviae*, but which Jordan¹⁵ has classified as *Salmonella enteritidis*. Jordan¹⁵ and Raebiger and Lerche¹⁶ state that *Salmonella typhimurium* is much more common than *Salmonella enteritidis*. Tenbroeck¹⁷ found the reverse to be true.

The organism isolated from our cases was a pleomorphic, Gram-negative bacillus varying from short coccoid forms to large bacillary ones. The smaller forms stained bipolar or barred and were the type usually seen in smears from exudates, especially if the organisms were numerous. The larger solidly staining bacillary forms were occasionally seen in animals and always in culture. No capsule was demonstrated. The organism was actively motile. Growth was profuse on all media. On plain agar the colonies were round, somewhat opaque, white, with a smooth edge. Good growth occurred on the Blair-Wilson medium, the colonies being lusterless and dull gray with considerable blackening of the medium. Lactose and sucrose were not fermented. Acid and gas were formed in glucose, mal-

TABLE I

Agglutination Titers of Various Members of the *Salmonella* Group With Their Respective Sera

	<i>S. Paratyphi-B</i> Serum	Strain I Serum	<i>S. typhimurium</i> Serum	<i>S. cholerae-suis</i> Serum
Strain I	1-6,400	1-10,000	1-2,500	1- 400
<i>S. typhimurium</i>	1-3,200	1- 6,400	1-2,500	—
<i>S. paratyphi-B</i>	1-6,400	1- 6,400	1-1,600	—

<i>S. enteritidis</i>	—	1- 100	—	—

tose, mannite, sorbitol, rhamnose, dulcitol, xylose, and mannose in 18 hours. After 4-7 days' incubation the dulcitol and sorbitol media became secondarily alkaline using brom thymol blue as an indicator. The methyl red test was positive in 24 hours. Indol was not formed after 4 days' incubation. Litmus milk was acid after 18 hours, becoming strongly alkaline after 3-4 days' incubation.

This bacillus was identified as *Salmonella typhimurium* from the serological tests. The tests were made with known members of the *Salmonella* group in stock and with antisera previously prepared against these stock strains. As most of the antisera were old, the titer was apt to be rather low. This was particularly true of the *Salmonella typhimurium* serum (titer 1-2,500). Tables I and II represent a typical protocol of the serological experiments. All agglutination tests were incubated at 37° C. for 2 hours and left overnight at 5° C. Absorption tests were placed in a 50°C. water bath for 2 hours and then placed in the icebox overnight.

Usually one massive absorption was sufficient to remove all the agglutinins for the absorbing organism. If this did not suffice, a second absorption was done using a smaller quantity of organisms. Two absorptions were the most ever required.

The pathogenicity of this organism for guinea pigs was readily proved. Three strains were used, one isolated from the spleen of an animal with chronic disease, one from the blood stream of an animal dying of the acute disease, and the third from a culture of feces. Subcutaneous and intraperitoneal injection of 10-20 million organisms into 6 animals produced death in 18 hours in 3, 1 died on the 4th day after injection, and 2 on the 5th day. The changes found at autopsy were the same regardless of the site of inoculation. There was considerable injection of the blood vessels over the abdominal musculature and beneath the skin. The peritoneum and pleura were markedly injected. Both the peritoneal and pleural cavities contained 3-10 cc. of thin, slightly yel-

lowish, albuminous fluid in which bacilli were easily demonstrated. In the animals which died within 24 hours, the viscera showed no changes, gross or microscopic, beyond an intense, hemorrhagic congestion and many fresh fibrinous adhesions about the spleen, over the dome of the liver, and occasionally between the loops of small intestine. In the 3 guinea pigs which lived for 4-5 days, the liver and spleen were found to have enlarged to about twice the normal size. In one animal dying on the 5th day many tiny white nodules were found throughout the spleen. Microscopically these were tiny areas of endothelial proliferation identical with those found in the naturally infected guinea pigs. The organisms were readily recovered from the blood, spleen, urine, and feces of these experimental animals.

PATHOLOGY

Two types of gross anatomical lesions, with all degrees of gradation between, were seen in the guinea pigs which were naturally infected. Some animals died of an acute hemorrhagic disease with lesions exactly like those found in our inoculated guinea pigs. In about half the spleen showed a slight but definite enlargement. Such animals in the cages would eat well and gain in weight until about 24 hours before death when they would appear listless with ruffled fur. In a few the time between the onset and death was so short that no evidence of illness was seen.

Most of our animals died of the chronic form of the disease. They appeared listless and had ruffled fur for 4-7 days before death, but continued to eat well until they were moribund, and the loss of weight was minimal. Indeed, in those guinea pigs killed routinely at the end of 6 weeks, such animals often appeared fatter and larger than their normal brethren.

At autopsy these animals had no

injection of the superficial blood vessels. The peritoneal and pleural cavities contained no fluid. Old fibrinous adhesions about the spleen and between the upper loops of small bowel and the stomach were common. The mesenteric lymph glands were, as a rule, only a little enlarged. The spleen was always enlarged, at times attaining a size of 4×2 cm. as against an average normal size of $2\frac{1}{2} \times 1\frac{1}{4}$ cm. The spleen always contained yellowish-white, firm nodules, ranging in size from those barely visible up to 2-3 cm. across and varying in number from 1 to 100 or more. At times the spleen contained definite abscesses, 5-10 mm. across, in the pus of which the *Salmonella* organism was easily demonstrated. Nodules similar to those occurring in the spleen were occasionally found in the liver and over the surface of the peritoneum. No gross pathological changes were found in the other organs.

Histologically the most typical lesions are seen in the spleen and consist of endothelial proliferation. This begins in the center of the lymph follicles and gradually increases until the entire follicle has been replaced by large endothelial cells, which form a solid, compact mass which may replace all or most of the normal splenic tissue. In the center of the larger nodules necrosis of the endothelial cells occurs together with the infiltration of many polymorphonuclear leucocytes. In the largest nodules the center is entirely composed of pus cells and cellular debris. The endothelial cells remaining outside of this central necrotic area become elongated and take on the appearance of fibroblasts. These cells form a sort of capsule so that grossly the entire nodule may be separated from the surrounding splenic tissue. The "capsule" always contains a few lymphocytes. Aside from some slight engorgement of the capillaries, there are no other lesions in the spleen.

The nodules in the liver and on the peritoneal surface apparently arise through the same process as those in the spleen. Accumulations of large mononuclear cells, having the appearance of endothelial cells, occur in these areas. These do not seem to arise from lymphoid follicles. In the largest nodules central necrosis and polymorphonuclear leucocytic infiltration occurs. The capillaries of both the liver and kidney are distended. No areas of endothelial cell proliferation were found in any organ other than those mentioned. Lesions in all of the organs have been reported at one time or another by other authors (Edington,⁸ Raebiger and Lerche,¹⁶ Howell and Schultz,⁵ Thomas,⁷ Duthie and Mitchell,⁹ and Nelson and Smith¹¹).

Differentiation between the chronic form of "pseudo-tuberculosis" and true tuberculosis, although usually not difficult, at times may be impossible. Histologically there is no difference between them. The tuberculous nodules produced by inoculation of guinea pigs arise from the proliferation of the endothelial cells with a secondary central necrosis and infiltration by polymorphonuclear leucocytes. Giant cells and typical tubercle formation as seen in human tuberculosis do not occur in the guinea pig. Care should be taken not to confuse the megalokaryocytes occasionally found in normal guinea pig spleens with tuberculous giant cells.

Differentiation is best made from the gross lesions. The characteristic feature of both diseases is the firm, yellowish-white nodules usually found in an enlarged spleen and occasionally distributed through the liver and over the peritoneum. Large caseous abscesses, which are not uncommon in "pseudo-tuberculosis," have never been found in our animals with true tuberculosis. Moreover, fibrinous abdominal adhesions appear to be more common in animals infected with *Salmonella typhi-*

murium than in those with tubercle bacilli. In tuberculosis the mesenteric lymph glands are large, caseous, and there is considerable matting together and thickening of the omentum. In "pseudo-tuberculosis" the glands are discreet and only slightly enlarged. However, considerable glandular enlargements may, in rare instances, be observed in "pseudo-tuberculosis" while the reverse picture of small discreet lymph glands and splenic nodules is not infrequently observed in our tuberculous pigs. Differentiation of the two conditions must depend on demonstrating the causative organism in the lesions. Routine smears from suitable caseous areas should be made in every instance, and no diagnosis of tuberculosis should be made unless acid-fast bacilli are found in such smears.

EPIDEMIOLOGY

Although shedding of the organisms through the intestinal tract was early recognized, attempts to infect guinea pigs by feeding have been unsuccessful or have succeeded only by the use of enormous numbers of organisms. Such experimental animals may show the organism in their feces but fail to develop any clinical disease (Smith and Nelson,¹² Petrie and O'Brien,⁴ Friedlander and Hertert¹⁸). Nelson¹⁴ has shown that healthy animals, placed in contact with sick ones under natural conditions, will become infected. However, Petrie and O'Brien⁴ and Duthie and Mitchell⁹ were unable to infect animals by this method.

As none of our guinea pigs ever showed lesions in the lungs, it would seem as though the infection were transmitted by way of the alimentary canal. Bacteria were found to be discharged from the sick animals in our herd through the feces and urine, so that it seemed certain that the large receiving pen and the food and water receptacles in it were thoroughly contaminated. In

order to demonstrate the communicable nature of this disease under natural conditions, 12 guinea pigs from a different source were obtained and their feces examined. None showed any organisms of the *Salmonella* group. Autopsies on about 50 animals from the same source showed that the stock was free from *Salmonella* infection. These 12 animals were placed in the main pen with 42 guinea pigs of the old infected stock. The animals remained together in the one pen from 9-3-38 until 10-24-38 when all survivors were killed. During this time 7 guinea pigs of the old stock died, and 6 of these were found to be infected with *Salmonella typhimurium*. Two of the 12 experimental animals died of this infection, one on 9-24-38 after an illness of 36 hours, the other on 9-29-38 after an illness of 6 days. One experimental animal was found to have the

chronic type of *Salmonella* disease at autopsy on 10-24-38. One other experimental animal (Exp. 10) was found to have the organisms in the feces although cultures of the spleen were negative and there was no gross evidence of infection.

During this experiment, fecal cultures were made from all of the new stock guinea pigs and from about half of the old ones. Table III contains a summary of the results in those cases in which a positive culture was obtained from the feces. It would appear that transitory infection of the animals does occur, probably indicating the occurrence of a carrier state, i.e., the harboring of virulent organisms by an animal not showing any clinical evidence of infection. Of course, the mere presence of bacteria in the feces does not mean that there is actual invasion of the body

TABLE III

Summary of the Positive Results Obtained in the Cross-Infection Experiment

Exp. = Guinea pigs from the new, uninfected stock
 CP = Guinea pigs from the original, infected herd

tissues. Reference has already been made to an instance (Exp. 10) where the bacteria were apparently living in the intestinal tract without harming the host. Table III shows also that ingestion of the organisms does not usually lead to clinical infection, as only 3 out of 9 of the animals from whose feces *Salmonella typhimurium* was recovered succumbed to the infection. It would seem that the animals either recover fairly promptly or succumb, as we found no instance of prolonged shedding of the bacteria unless the animal was clinically ill.

Raebiger¹⁹ states that agglutinins are formed during the course of the disease and may be used for determining the presence or absence of infection in a herd. From 47 of our animals blood was taken for agglutination tests. Of 4 animals dying of the chronic disease, 2 had no agglutinins while the other 2 had a titer of only 1-10. One animal killed after an illness of almost 2 weeks had a titer of 1-100. Of 4 animals which appeared to be healthy, but were found to be infected at autopsy by culture, 3 had no agglutinins and the 4th a titer of 1-400. The last presented no anatomical lesions although the culture of the spleen showed that *Salmonella typhimurium* was present. Five animals were killed from which no positive cultures were obtained at autopsy; 3 of these had no agglutinins, 1 a titer of 1-400 but no anatomical evidence of past infection, 1 a titer of 1-10 with many fibrinous adhesions about the spleen. Conclusions cannot be drawn from the remaining animals because of insufficient data. The highest titer found was 1-800 in a pregnant female, never known to have been infected and which had no anatomical evidence of past infection at autopsy. Her history before reaching our pens is unknown. From the data gathered it would appear safe to conclude only that an animal

may develop agglutinins against the infecting organism, but the absence of such agglutinins does not mitigate against the presence of "pseudo-tuberculosis," either present or past, in the herd.

The original source for this infection is not known although the dealer's own breeding stock was found to be infected. He stated that the guinea pigs on his farm never showed any signs of illness. Those animals examined by us appeared healthy while alive although definite pathological and bacteriological evidence of infection was obtained from them at post-mortem examination. It seems likely that this was a latent infection which was stirred up by the change in diet and the inoculation given the guinea pigs in this laboratory. Such factors are difficult to evaluate, and no control experiment was carried out by us to determine the truth of this hypothesis. Other writers on this subject have found such factors to exist. Edington⁸ found that low vitamin diets, severe temperature changes, or mechanical injury to the gastrointestinal tract rendered animals more susceptible to infection. Nelson¹⁴ noted that pregnant sows were most apt to be infected, an observation which was not found to be true among our animals. Okamoto²⁰ found that the parenteral injection of organ extracts was enough to activate a latent infection already present in the guinea pig.

Our efforts in combating this epizootic were directed toward the prevention of spread of the disease rather than to the cure of the individual animals. All the small cages were cleaned with hot water and sterilized after each lot of animals was killed. The large receiving pens were likewise thoroughly cleaned with hot water and lysol before any new guinea pigs were admitted to the colony. Scattered reports in the literature indicate that fresh vegetables, when fed to the animals in large

amounts, will aid in combating the disease; in our hands the results obtained were unsatisfactory. Vaccines and immune sera were not tried although Howell and Schultz,⁵ Nichols and Stimmel,²¹ and Rake²² have reported some success with the use of the former. By the use of simple cleansing methods, our colony has been free of infection for the past 6 months.

SUMMARY

1. An outbreak of "pseudo-tuberculosis" among guinea pigs is reported.

2. Chronic *Salmonella* infection of guinea pigs due to *Salmonella typhimurium* cannot be differentiated from tuberculosis by gross anatomical or histological methods. The demonstration of tubercle bacilli in routine smears made from the caseous lesions in the guinea pig is the only reliable way to tell the two conditions apart.

3. The infection is probably spread by means of infected feces and urine. A true carrier state, temporary at least, may develop in individual animals.

4. The organisms are most often found in the spleen. Inability to demonstrate the organisms in fecal cultures does not mean that the animal is not infected.

5. Agglutinins may or may not be formed during the course of the disease. When present they are indicative of successfully combated previous infection rather than of present infection.

6. The presence of a *Salmonella* infection is not incompatible with an appearance of exceedingly good health on the part of the animal.

Zoölogical Problems Relative to Meat Inspection and Their Bearing on Public Health

BENJAMIN SCHWARTZ, PH.D.

*Chief, Zoölogical Division, Bureau of Animal Industry,
U. S. Department of Agriculture, Washington, D. C.*

OF THE hundreds of species of protozoa, helminths, and arthropods that parasitize animals that are used for human food, comparatively few are of importance in meat inspection. From the viewpoint of livestock production all parasites must be regarded as injurious or potentially injurious. From a meat inspection standpoint, however, the only parasites that are regarded as important are (1) those which occur in the edible portions of carcasses and are directly transmissible to man; (2) those which occur in the edible portions of carcasses and are indirectly transmissible to man through other hosts; and (3) those which, by their mere presence, or because of the pathological conditions which they produce in the edible portions of carcasses, render the affected parts objectionable as human food. Naturally, the parasites that are directly transmissible to man are of greatest importance, and the meat inspection regulations of various countries contain provisions for eliminating this danger to human health.

PARASITES DIRECTLY TRANSMISSIBLE TO MAN

Fortunately, the only species of parasites occurring in the flesh of food animals that are directly transmissible

to man are the bladder worms of the beef and pork tapeworms, respectively, and the larvae of trichina. While tapeworms may be more or less deleterious to human health and may even affect seriously delicate and nervous persons, the pathogenicity of trichinae has been established beyond question, the latter parasites being capable of producing serious illness and even death in human beings. The prevention of human infestation with the three species of parasites mentioned cannot be wholly effected through meat inspection alone; meat inspection can and does assist materially in controlling infestations of human beings with these worms. A system of meat inspection which supervises the slaughter of all food animals, coupled with care in the preparation of meat for the table, should eventually control and even eradicate these three parasites that are directly transmissible from food animals to human beings.

RECENT INVESTIGATIONS ON CYSTICERCI IN BEEF AND THEIR BEARING ON MEAT INSPECTION

During the last few years scientific investigations regarding the vitality of cysticerci of *Taenia saginata* have led to an important modification in meat inspection procedure with regard to this

parasite. Up to 1931 it was generally assumed that the vitality of cysticeri in beef was completely destroyed following the retention in the cooler of infested carcasses for a period of 21 days. This assumption was based on tests first carried out by Perroncito⁴ in Italy, and later extended greatly by Ostertag³ in Germany. Perroncito determined that all cysticeri in an infested calf carcass were dead 14 days after the animal had been slaughtered; Ostertag showed, however, that the natural death of cysticeri in beef did not occur uniformly in a 2 week period, but that in 3 weeks following the death of the infested host animal all the cysticeri were dead. Ostertag's observations were based on various tests applied to determine the vitality of the cysticeri following the retention of the infested carcass for 3 weeks, these tests being supplemented by human feeding experiments in which Ostertag himself and a number of assistants and students of the Berlin Veterinary College participated. These tests involved the swallowing by the human volunteers of cysticeri obtained from beef carcasses which had been retained for 21 days, with negative results so far as the development of tapeworms in the human intestine was concerned. On the basis of this searching investigation, the retention for 21 days of beef carcasses infested with cysticeri was incorporated in the meat inspection regulations of Germany and was later incorporated in the regulations governing the meat inspection of the U. S. Department of Agriculture.

In 1931 Schmey and Bugge in Germany published^{8, 9, 10} the results of investigations which cast considerable doubt on the effectiveness of a 21 day retention period in completely destroying the vitality of *Cysticercus bovis*. These investigators determined that not all of the cysticeri present in beef were destroyed in 21 days; some of the

cysticeri present in lightly infested beef carcasses still showed some sign of life even after 41 days' retention, viability being determined by certain biological tests involving the demonstration of the ability of the cysticeri to evaginate the heads and the demonstration of ciliary movement in the flame cells of these worms. Schmey and Bugge determined, moreover, the important fact that cysticeri removed from carcasses that had been retained by them in the cooler for 28 days were still capable of developing into strobilate tapeworms in the intestine of man. Of the 6 volunteers who swallowed a total of 105 cysticeri from beef that had been retained 28 days, 3 became infested and 6 mature strobilate tapeworms were removed from these subjects following anthelmintic medication.

The work of these investigators having been confirmed by Clarenburg¹ in Holland, so far as the viability of cysticeri was concerned following the retention of infested carcasses up to 41 days, investigations were undertaken in the Zoölogical Division of the Bureau of Animal Industry to test the soundness of these new observations. In 1933, 3 infested beef carcasses were retained in the cooler of a meat packing establishment in Chicago for 21 days or longer; at the end of 21 days it was determined that most of the cysticeri showed movement and that from 60 to 100 per cent of various lots of these worms were capable of extruding their heads in suitable media, this being sound evidence of viability. Nearly similar results were obtained when infested carcasses were retained in the cooler for 25 and 26 days, respectively, but after retention for periods ranging from 31 to 48 days there was no evidence of life in the cysticeri. One worker in the Zoölogical Division swallowed several cysticeri from beef that had been retained in the cooler for 26 days; although these cysticeri were

still showing signs of life, he failed to show evidence of infestation with tapeworms.

Although the evidence obtained in our investigations was at variance with those published abroad, the results obtained did show that the 21 day retention period, previously accepted by parasitologists and meat inspection experts as adequate for the destruction of the vitality of beef cysticerci, did not destroy life in those parasites in all cases.

The discrepancy in the results obtained by Ostertag many years ago and those obtained more recently in Germany have been ascribed to the improvement in refrigeration in recent years, the assumption being that the superior cooler refrigeration facilities at the present time favor the survival of cysticerci rather than hasten their devitalization. According to this assumption, the imperfect cooler refrigeration of previous years was responsible for the comparatively early death of cysticerci by hastening certain changes in the meat that produced deleterious effects on the parasites. It is quite possible that the differences between our results and those in Europe might be accounted for, at least in part, on the basis of differences in conditions prevailing in the meat coolers used in this country and those used abroad. Regardless of the true explanation, however, our work demonstrated conclusively that it was no longer proper to include in the regulations the 21 day retention period as an effective method for the destruction of the vitality of *Cysticercus bovis*, and this requirement was accordingly eliminated from the regulations. The alternative requirement, involving the refrigeration of infested carcasses for not less than 6 days at a temperature not higher than 15° F., based on investigations by the late Dr. B. H. Ransom⁶ has been retained in our regula-

tions because the more recent investigations in Europe on the effects of low temperatures on the vitality of cysticerci have shown that the retention period required under federal meat inspection is more than adequate to destroy life effectively in these parasites. According to the later European work by Schmey and Bugge,⁸ *Cysticercus bovis* loses its vitality when infested carcasses are retained for 4 days at a temperature of 14° to 17.6° F. (—10° to —8° C.) the effective period being 2 days less than that required under our regulations. Viljoen¹² has concluded also that no cysticerci will remain viable after 6 days' continuous freezing.

INVESTIGATIONS ON TRICHINAE

During the last 10 years human trichinosis has been assuming increasing importance as a public health problem; the number of cases reported in the medical literature and elsewhere during this time has shown a sharp increase. From 1842, when trichinosis in man was first diagnosed in this country, up to 1915, when all the known cases were summarized by Ransom,⁷ the total number of recorded cases of human trichinosis in this country was approximately 1,500. From 1915 to about 1925 the number recorded annually in this country was comparatively low. Since 1925 there has been a marked increase, the total number in 1937 being between 5,000 and 6,000. In other words, the number of cases during these 22 years is from 3 to 4 times that recorded for the previous 73 years.

While it cannot be determined on the basis of available evidence whether the increase in the cases of human trichinosis in this country is only apparent or real, in the opinion of the writer this increase is largely apparent because of the increased interest in this disease by the medical profession, and their increasing vigilance in establishing

a correct diagnosis. The increased interest by the medical profession is due almost entirely to certain statistical information on the prevalence of trichinae in human diaphragms examined by various investigators by the digestion or other improved technic.

Following Queen's report⁵ which showed that trichinae were found by him in about 17 per cent of 500 diaphragms obtained from consecutive human necropsies in Rochester, N. Y., and in about 27 per cent of 200 diaphragms from Boston, a number of workers who have followed up this type of investigation have brought to light facts which show conclusively that the incidence of infestation of man with trichinae in the United States is much greater than had ever been suspected. In a recent summary covering 1,000 diaphragms examined at the National Institute of Health, Washington, D. C., Nolan and Bozicevich,² the incidence was found to be 17 per cent.

It is important to bear in mind that the surprisingly high incidence of trichina infestation in human beings in the United States, as determined by the examination of diaphragms by the digestion technic or by sectioning, or by repeated examination of press preparations, is of significance, despite the fact that very few of the individuals in whose diaphragms trichinae were found post-mortem were known to have suffered from trichinosis during life. The findings indicate conclusively that many persons intentionally or unwittingly eat pork that is raw or nearly raw, and as a result acquire an infestation with trichinae. This in turn indicates that sources of trichina infestation are present in the United States and that the extent of this infestation is sufficient to affect in some localities up to 25 per cent or more of the population, assuming that the sampling of human diaphragms, as recorded, was adequate from a statistical viewpoint.

INCIDENCE OF TRICHINAE IN SWINE

In order to ascertain the prevalence of trichinae in swine, and to determine the main sources of this infestation, so far as human beings are concerned, the Zoölogical Division in coöperation with the Meat Inspection Division of the Bureau of Animal Industry inaugurated in 1933 an extensive survey, the object being to determine by random sampling the incidence of trichinae in garbage-fed hogs and in grain-fed hogs in various parts of the United States, to check the effectiveness of the Bureau's prescribed methods for destroying the vitality of trichinae in meat food products containing pork muscle tissue that are customarily eaten without cooking, and incidentally to ascertain the prevalence of trichinae in prepared meat food products of kinds that are not processed for the destruction of life in trichinae under the requirement of the U. S. Bureau of Animal Industry. The latter served as a check on the technic used in our investigations for the processed products. The technic used involved the artificial digestion in an incubator of approximately $\frac{1}{2}$ lb. samples; this was also followed for samples of fresh pork.

The results in grain-fed and in garbage-fed hogs to June 30, 1937, have been summarized by the writer,¹¹ as follows:

Out of 6,622 * samples of diaphragm muscle tissue obtained from as many grain-fed hogs originating in the South, the Middle West, the North-Central States and in some of the Eastern States, only 60, or 0.91 per cent, were found to be infested with trichinae; out of 6,484 * diaphragm samples from as many garbage-fed hogs, 286, or 4.41 per cent, were found to be infested. These data show an incidence of trichinae in garbage-fed hogs about 5 times as great as in grain-fed hogs.

* The figure given in the previous publication is incorrect due to a typographical error.

Since July 1, 1937, additional data have been collected, with results that are even more striking. Out of 2,901 diaphragms collected in federally inspected establishments in Chicago and Kansas City from grain-fed hogs originating in the Middle West, 34, or 1.17 per cent, contained trichinae; the number of trichinae in individual diaphragms ranged from 1 to 1,113. However, of the positive diaphragms 76.4 per cent contained less than 5 larvae, this type of infestation being practically negligible. Out of 2,847 samples of diaphragms obtained from as many garbage-fed hogs in an important garbage-feeding center on the Atlantic seaboard, 286, or 10.04 per cent, contained trichinae; the number of trichinae in individual diaphragms ranged from 1 to 69,700. Of the positive diaphragms only 19.3 per cent contained less than 5 larvae.

These data demonstrate conclusively that pork from garbage-fed hogs is the main source of trichinosis for man, if such pork is eaten raw or after only partial cooking or inadequate curing. The available data are sufficiently extensive to warrant the preliminary conclusion that about 1 per cent of the grain-fed hogs in this country harbor trichinae, whereas from 4.5 to 10 per cent of garbage-fed hogs are infested, the degree of infestation being much greater than in hogs not fed on garbage.

INCIDENCE OF TRICHINAE IN MEAT FOOD
PRODUCTS CONTAINING PORK
MUSCLE TISSUE

During the last 5 years there have been examined in the laboratories of the Zoölogical Division 10,754 individual $\frac{1}{2}$ lb. samples of various meat food products containing pork muscle tissue. The samples were obtained through federal inspectors in charge of meat inspection, who submitted, in connection with each sample, data as to the method of processing and informa-

tion as to whether the product was of a kind customarily eaten without cooking in the home. Each sample, properly identified as to class and place of origin, was ground and digested in a fluid containing pepsin and hydrochloric acid in an incubator for about 24 hours. Live or dead trichinae, if present, could be recovered from the sediment of the digestive fluid.

Of the samples so examined, 9,788 were from products processed under Bureau requirements to insure the destruction of life in trichinae, and 966 were from products not so processed.

The samples of products processed for the destruction of life in trichinae—such as bologna, frankfurters and Vienna sausage, various kinds of dry or summer sausage, cooked ham and Italian-style ham—were obtained from federally inspected establishments and represented a good cross-section of these products that are released to the consuming public. The processing included heating and special refrigeration, as well as the various prescribed curing methods. The results obtained were as follows:

Out of the 9,788 specially processed samples, trichinae were found in only 75; 71 contained only dead, uncoiled trichinae and 3 contained trichinae showing feeble movements. Feeble trichinae were found in 3 samples of smoked sausage, the number in the 3 samples being 1, 1, and 3, respectively; a single coiled but dead trichina was found in a skinless frankfurter. It is important to note that the feeble worms referred to were not tightly coiled and deep brown in color as are decapsuled trichinae whose vitality has not been reduced by heat, cold, or other processing. They were loosely coiled and rather pale, but slight movements could be induced by the application of a heated glass rod to the bottom of the glass dish in which they were. Large num-

bers of worms similar in appearance and activity to those just described have been fed to rats in our laboratory at various times in order to determine whether they are capable of surviving and growing in the intestine and producing a new generation of worms. In no instance have such worms succeeded in remaining alive in the intestine of susceptible rats, as determined by the results of a searching examination of the intestines of these experimental hosts 24 hours later. A number of rats to which such worms were fed by stomach tube, or which swallowed relatively large quantities of meat containing such worms, were killed after one month. Following the removal of skin and viscera, the entire carcass of each rat was digested without yielding any trichinae.

Of the 966 products not processed under the requirements as to the destruction of the vitality of trichinae, 480 (nearly 50 per cent) contained these parasites; of the 480 positives, 435 contained only dead trichinae, and the remaining 45 contained live and dead trichinae, the number of live worms per sample ranging from 1 to 14.

ECHINOCOCCUS CYSTS

Of the parasites occurring in the edible parts of food animals that are transmissible to man indirectly, that is, through an intermediate host, hydatid cysts, *Echinococcus*, are the most important. The cystic stage of this parasite develops into strobilate tapeworms in the intestines of dogs, cats, and certain wild carnivores, the feces of the infested carnivores constituting a source of infection for human beings and all classes of domestic animals. An infestation with hydatids in man is a serious condition, and treatment involves a major surgical operation for the removal of the cysts. As the cysts usually lodge in the liver and may occur in other vital organs, particularly the

lungs, it is evident that their removal by surgery involves a serious risk to life.

The occurrence and suspected occurrence of *Echinococcus* infestation in man in this country may be inferred from the repeated requests which come to the Bureau of Animal Industry for an antigen that is used in the complement-fixation test for the diagnosis of this parasitic infestation in man. Through an arrangement with the U. S. Naval Medical School, swine livers infested with *Echinococcus* are forwarded to that school from time to time for the preparation of the antigen and its distribution to physicians and hospitals. During the last 3 or 4 years it has been rather difficult to obtain infested livers from federal inspectors. The station at Richmond, Va., for years a reliable source of supply, is now having some difficulty in obtaining the material needed.

It is probable that meat inspection is largely responsible for what appears to be a sharp decrease in the incidence of *Echinococcus* infestation in swine and other animals. The condemnation of affected organs and cysts and their consignment to the tank cuts down the source from which dogs, cats, and wild carnivores acquire the hydatid tapeworm, thereby destroying the vicious cycle of a parasite that is dangerous to human and animal health.

SUMMARY

An effective system of meat inspection promotes public health (1) through the condemnation of parts of or entire carcasses of food animals containing parasites that are transmissible to man directly and indirectly; (2) through special processing for the destruction of trichinae, and of cysticerci not discoverable by macroscopic examination; and (3) through the condemnation of parts of carcasses or of entire carcasses in which parasitic infestations not trans-

missible to man, but objectionable from esthetic and other standpoints, are so generalized that the parasites and lesions cannot be removed by trimming.

Meat inspection is also an effective control measure for certain parasites, notably tapeworms, that occur as immature forms in edible portions of carcasses; through the condemnation of parts of carcasses so affected, the vicious cycle of these parasites is interrupted. Meat inspection must be regarded, therefore, as one of the important prophylactic measures for the control of parasites affecting livestock as well as human beings.

Certain parasitic infestations transmissible from food animals to human beings cannot be controlled by meat inspection alone; however, a sound inspection system can and does contribute materially to control of certain parasitic infestations of man; in the absence of inspection these parasites would probably constitute a serious human health problem.

Meningococcus Meningitis in the District of Columbia

C. C. DAUER, M.D., M.P.H., F.A.P.H.A.

Epidemiologist, Health Department, District of Columbia, Washington

IN general the occurrence of meningococcus meningitis in the District of Columbia has been similar to that in other urban communities of the United States.^{1, 2, 3} Since 1910 there have been two sharp outbreaks of the disease. The epidemic in 1918 was preceded by a moderate increase in prevalence in 1917. The 1935 outbreak was more explosive in type and during the following 2 years the incidence was above the normal expectancy (see Figure I). In 1931 the incidence of the disease was above the average but not severe enough to classify as an epidemic. In the intervals between these outbreaks

the incidence has been at a fairly low endemic level.

Seasonal occurrence—As in other parts of this country, the disease has been reported most frequently in the late winter and spring months, and least frequently in the fall. The epidemic in 1935 had its peak in March. This epidemic was characterized by a rapid increase in cases from January to the latter part of March when the peak was reached (see Figure II). Most of the cases reported early in the epidemic came from well defined areas in the city where housing and sanitary conditions have been far from desirable.

FIGURE I—Incidence of Meningococcus Meningitis in the District of Columbia, 1911-1938

FIGURE II—Number of Cases of Meningococcus Meningitis Reported in the District of Columbia by Weeks from December, 1934, to February, 1937, inclusive

The secondary rise in the number of cases in May of 1935 was due to a large number of cases among colored persons reported from all sections of the city. The decline in the number of cases reported by weeks was much more gradual than the increase at the beginning of the outbreak. Throughout 1935 the number of cases reported each week continued at a fairly high level. The seasonal increase in cases in the winter and spring of 1936 was a gradual one and to a point far below the peak of the previous year. Throughout 1936 the number of cases continued to decrease. The seasonal increase in cases in 1937 was still lower than in 1936, and in 1938 the disease once more assumed a low endemic level.

Racial distribution—As shown in Table I, case rates and death rates from

meningococcus meningitis in the District of Columbia have been higher in the colored population than in the white, with few exceptions. The ratio of colored to white rates has usually been about 2 or 3 to 1. In some years the incidence of the disease has been about equal in the two racial groups, but in years of epidemic or increased prevalence the colored rates have been 2 or 3 times higher than the white.

Sex differences in incidence and mortality—The incidence of the disease in males has invariably been higher than in females. The ratio of male to female cases has been about 2 to 1 in both white and colored persons. Under 20 years of age the male to female ratio was about 1.5 to 1, and from 20 to 40 years varied from 3.1 to 6.1.

TABLE I

Number of Cases and Deaths, Rates per 100,000 Population, and Case Fatality per 100 Cases, from Meningococcus Meningitis, 1928-1937

Year	Cases		Deaths		Case Rate		Death Rate		Case Fatality Rate	
	White	Colored	White	Colored	White	Colored	White	Colored	White	Colored
1928	5	2	3	1	1.4	1.7	0.9	0.8	60.0	50.0

All ages	45.1	39.5	40.8	45.6	2.4	1.9

Case fatality rates—It can be seen in Table I that case fatality rates have varied from year to year, with less variation for white than colored cases. The average for the 10 year period from 1928 to 1937 was 44 per cent for both white and colored groups. Although the incidence of the disease has been higher among males, the fatality rates have been approximately the same for males and females. For the cases reported in 1935 and 1936 the case fatality for white males was 45.1 per cent, 39.5 for white females, 40.8 for colored males, and 45.6 per cent for colored females.

Age distribution of cases and deaths

—The distribution of cases showed

wide variations in the different age groups, the greater proportion of cases being in the younger groups. Forty-two per cent of white cases and 68 per cent of the colored occurred in persons under 20 years of age. The case rates per 100,000 population for the various age groups likewise reflect the greater prevalence in the younger age groups.

There was very little difference in the death rates from meningococcus meningitis by age groups in the white population, but in the colored the rates were much higher in children under 5 years of age. In the latter there was a decline in mortality as age increased.

Case fatality rates were fairly low in the younger age groups and increased

with age. Case fatality was higher in infants under 1 year of age than in the 1 to 4, and 5 to 9 year groups, but appreciably lower than in the older ages, *i.e.*, 40 years and over. The fatality rates for males and females were essentially the same when all ages or specific age groups were compared.

Geographical distribution in the District of Columbia—The geographical distribution of meningococcus meningitis cases in the District of Columbia has exhibited no unusual characteristics. In general the disease has occurred most frequently where housing conditions are bad and poor hygiene has been most commonly practised. In the white population the incidence in 1935 and 1936 was highest in the central part of the city where a large pro-

portion of the population has lived under these undesirable conditions. In this area a group of 7 census tracts, in which about 8 per cent of the white population of the city resides, furnished 28 per cent of the white cases in 1935 and 1936. The case rate for this group was 57 per 100,000 population, and for the remainder of the city's white population the rate was 12.6. However, in other scattered sections where environmental conditions were about as unsatisfactory, the case rates were about the same as those of the group described above. The incidence was generally low (10 or less per 100,000 population) in the better residential sections.

The disease was more evenly distributed in the colored population.

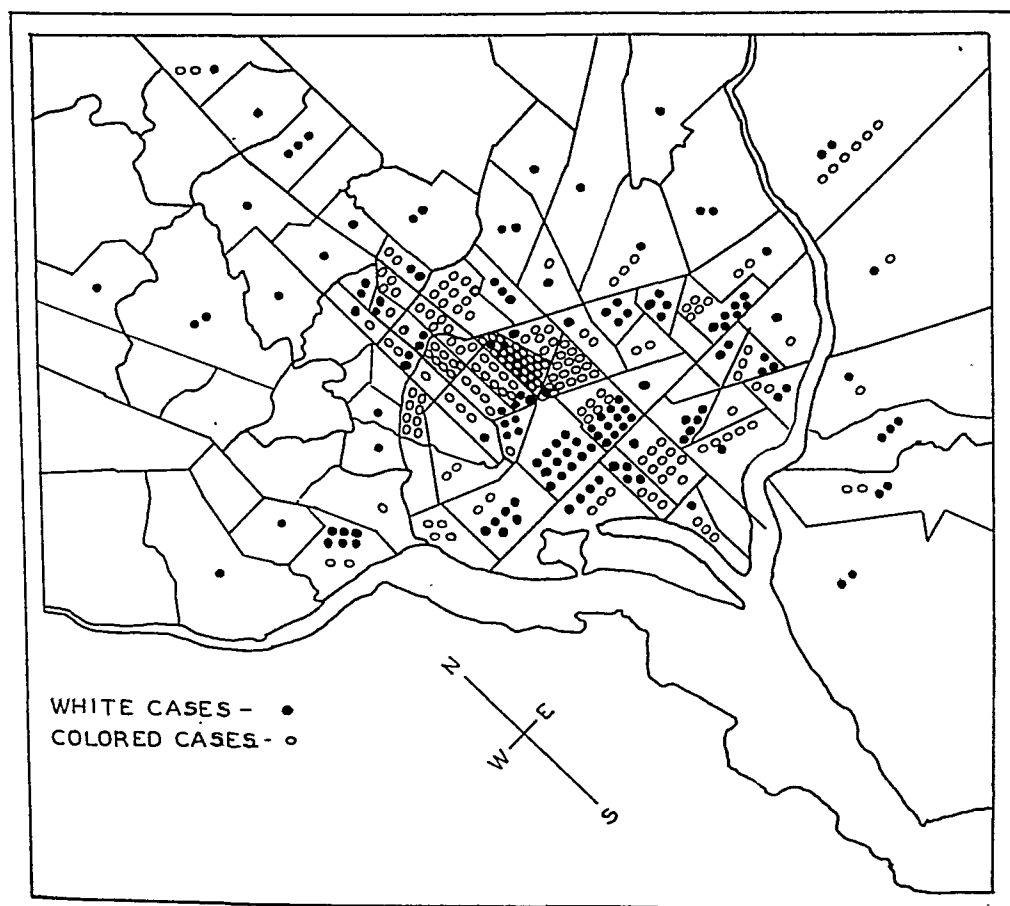

FIGURE III—Geographical Location of Cases of Meningococcus Meningitis Reported in the District of Columbia during 1935 and 1936

Sixty per cent of all colored cases reported in 1935 and 1936 came from a section roughly 12 blocks wide and 30 blocks long extending through the center of the city immediately west of North Capitol and South Capitol Streets. Fifty per cent of the colored population in the District of Columbia resides in this section. The case rate was 70 per 100,000 population. Other smaller areas in the city where there was a concentration of colored population had approximately the same incidence rate as the larger area. The more even distribution of the disease in the colored population probably occurred because a large proportion of these people have lived under conditions which have favored the spread of the disease. It should be noted that there was not a wide difference in case rates of white and colored populations, 57 and 70, respectively, which lived under somewhat similar conditions.

The first cases to be reported in 1935 came from the two areas described above and the majority of the cases reported from other areas occurred later in 1935 and 1936.

Occurrence in family groups, institutions, etc.—Multiple or second cases in family groups were not reported frequently. In 1935 and 1936, two cases in the same family occurred only once among white persons, and in two instances among the colored. Four cases occurred in one colored family.

There were numerous instances where two or three cases were reported within a short space of time from adjoining houses or in the same block. Two cases were reported from the same address but in different families on two different occasions.

Meningococcus meningitis occurred in a number of institutions in or controlled by the District of Columbia. Four cases were reported from three of the penal institutions in 1935 and 1936.

Eleven cases occurred among transients early in 1935. These men were housed in two rooming houses patronized exclusively by transients. In 1936 one case occurred in the National Training School for Boys, and in 1937 there were 6 cases in this institution. The average enrollment is about 400 boys, mostly between 15 and 20 years of age.

Study of hospital admissions—Practically all of the cases of meningococcus meningitis reported in the District of Columbia have been admitted to the various hospitals in the city. Hospital records of 118 white and 167 colored patients with the disease who were admitted to two hospitals, were reviewed for information of epidemiological interest. This group of cases, admitted during 1935, 1936, and 1937, constituted a little more than two-thirds of all the cases reported to the Health Department during this period.

In this series of cases studied, it appears that fatality rates depend more on the age of the patients than on the length of the interval between the onset and the institution of treatment. Patients whose treatment began 2 days or less following the onset had as high a fatality rate as those whose treatment began 3 to 5 days after the onset. Further analysis of the former group showed no essential difference in fatality rates of those admitted on the same day as the onset, those admitted the day after, or the second day after the onset. This group undoubtedly included nearly all of the severe or fulminating types of infection many of which succumb in spite of early and vigorous treatment.

A comparatively small number of patients were admitted to the hospital 6 to 9 and 10 days or more after the onset of symptoms. Fatality rates in the 6 to 9 day group were higher than all other groups but the number was too small to permit drawing any definite conclusions. Those admitted

TABLE III

Fatality Rates per 100 Cases of Meningococcus Meningitis Admitted to Two Hospitals in 1935 to 1937, Inclusive, by Age Groups and Number of Days After Onset of Symptoms

Days After Onset	Age Groups								Total
	Under 1 Yr.	1-4	5-9	10-19	20-29	30-39	40-49	50+

Total	42.8	13.0	28.0	35.7	50.0	62.5	100.0	80.0	38.3

x No Cases

on the 10th day or later had the lowest fatality rate.

It is interesting to note that fatality rates increased materially with age whether the patients were admitted early or late following the onset of symptoms.

Definite information on the different types of meningococci present in the spinal fluid or blood stream of the hospitalized cases was available for only a few cases. However, the organism was found by direct smear or by culture in about 85 per cent of all cases. The importance of typing has been pointed out by Branham.⁴

Although the type of treatment varied in the two hospitals, there was no significant difference in case fatality rates among cases of similar age. One hospital admits only children, and the other is an isolation unit of a general hospital. Antitoxin was used extensively in the former and antimeningococcus serum in the latter. In both institutions sulfanilamide or one of its derivatives was used in the treatment of a small proportion of cases in 1937.

Case fatality rates in antitoxin treated and antimeningococcus serum treated cases were essentially the same when cases of the same age were compared. The series of cases in which sulfanilamide therapy was used was too small to warrant drawing any conclusions regarding its effectiveness.

Discussion—In general the epidemiological features of meningococcus meningitis have been no different in the District of Columbia than in other large cities. There have been epidemics at irregular intervals, a greater incidence in late winter and spring, a greater incidence in colored persons, a relatively high ratio of male to female cases, and a higher case fatality in older than in young persons. The relatively high incidence and mortality rates among males has been due mainly to the great excess of cases in males from 20 to 40 years of age. Differences in occupation and other environmental factors leading to more frequent exposure to infection have been suggested to account for the greater incidence in males. The fact that case fatality rates

are essentially the same for groups of males and females of the same age lends weight to this suggestion.

Studies in which the effect of various therapeutic agents, particularly sulfanilamide, on the fatality rate of meningococcus meningitis have been reported, were reviewed by the author. Few reports seem to indicate that careful thought has been given certain factors, other than the form of treatment, which affect fatality rates. These factors are: (1) age distribution of cases; (2) type of organism found; and (3) the period of time in which the cases occurred. In order that valid conclusions may be drawn, it is essential that the age distribution of specially treated and control groups be the same, or a sufficient number of cases in various age groups must be included in each series. The classification of cases according to type of meningococcus found is also essential in appraising the effects of various forms of treatment. Series of cases must extend over the same period of time because of the possibility of differences in virulence of the organism from year to year.

Banks⁵ in his report on sulfanilamide treatment of meningococcus meningitis took the above mentioned factors into

consideration and concluded that sulfanilamide was an effective therapeutic agent. Other reports^{6, 7, 8} are less convincing because there are no definite data with respect to factors other than treatment. The superiority of sulfanilamide over other forms of specific therapy does not seem to have been demonstrated satisfactorily up to the present time.

NOTE: The author wishes to take this opportunity of thanking Dr. Sara E. Branham of the National Institute of Health for helpful suggestions in the preparation of this manuscript.

A Permanent Nephelometer from Pyrex Glass

JOHN H. BREWER, PH.D., AND E. B. M. COOK

*Bacteriological Laboratory, Hynson, Westcott & Dunning, Inc.,
Baltimore, Md.; Biologic Division, Texas State Department
of Health Laboratories, Austin, Tex.*

THE use of nephelometry in the standardization of bacterial suspensions has been greatly handicapped because of the instability of the standards usually employed. Standards made with the actual organisms rapidly undergo autolysis even in the presence of strong bacteriostatic agents, and those prepared by chemical precipitation methods have the disadvantage that the crystals grow by accretion and one is soon reluctant to depend upon them. Barium sulphate standards¹ and the usual silica standards² have the additional disadvantage that when the proper turbidity is reached transmitted light assumes a greyish-white opalescence, whereas, the bacterial suspension has an amber cast. This discrepancy is due for the most part to the difference in size of the particles.

A method for reducing pyrex glass chips to the size of bacteria and grading them for nephelometric work was discovered entirely by accident while preparing glass chips for grinding rabbit brains for rabies vaccine. Discarded pyrex beakers and flasks were broken into chips about one-half to one inch in size and were placed in a pyrex flask or wide mouth bottle to about one-fourth of the capacity. They were then covered with distilled water and

placed on a shaking machine. This machine was run for 45 minutes over a 4" arc at 120 strokes per minute in order to remove the rough edges from the chips. For lack of sink space the distilled water from these chips was decanted into a cylindrical discard jar. After several days it was noted that the turbid liquid had settled into several distinct layers, one of which closely approached the appearance of typhoid vaccine. Noting this, we became interested in preparing a set of vaccine standards which would not settle out as rapidly as the freshly prepared barium sulphate standards which we had been using. The turbid layer of the glass suspension which most closely resembled the typhoid vaccine was siphoned off and concentrated by evaporation in order to make a range of standards. The glass standards were then calibrated by preparing bacterial suspensions of known count (Helber cell, Wright and Hopkins tube methods) and matching the concentrated solution by dilution to the bacterial standards. The resulting glass standards could not be differentiated from the bacterial suspensions whether in transmitted or reflected light. When the particles were measured it was found that they varied from 0.5 to 3.5

microns in diameter, which is the range of most of the organisms in which we were interested.

The difference in the size of these glass particles and freshly prepared barium sulphate is readily shown if one filters these suspensions through a very hard filter paper. The barium sulphate particles are removed by this filtration but the glass suspension remains turbid. This filtration method has been used by one of us to grade the size of the particles, rather than the sedimentation or centrifugation methods.

The rate of settling of the glass standards is much slower than that of the usual silica or barium sulphate type. Pyrex standards, properly prepared by this technic, will not settle out completely within 3 weeks although signs of sedimentation will be noted within 24 hours. They can be resuspended immediately by shaking a few times and will show no signs of accretion. The chemically precipitated standards will settle out completely within a few hours. Microscopic examination of the glass standard reveals "Brownian movement" similar to that noted in suspensions of bacteria of comparable size and density.

The accuracy of these standards will be seen in Table I.

This accuracy with a nephelometric method is possible only when using standards which match the suspensions in transmitted and reflected light. It is therefore necessary that the size of the particles in the standard be within the size range of the bacteria in the suspension.

TABLE I
Comparative Counts With Typhoid Vaccine

Stock	Nephelometer Reading	Direct Count
		With Levy Hausser Counting Chamber
1 T*	21,000 M	20,600 M
2 T	23,000 M	22,000 M
3 T	25,000 M	24,100 M
4 T	25,000 M	26,000 M
5 T	26,000 M	25,200 M
6 T	18,000 M	15,000 M
7 T	23,000 M	20,300 M
8 T	23,000 M	22,000 M
9 T	29,000 M	27,600 M
1 A†	24,000 M	23,400 M
2 A	27,000 M	26,700 M
3 A	27,000 M	29,000 M

* Stock T is a combination of 6 strains of *Eberthella typhi*.

† Stock A was made from the Kessel stain No. 501 A.

The stability of these pyrex glass standards is shown by the fact that standards which have been in constant use for 5 years give the same reading now as when originally made. The glass particles measure the same and show no tendency to clump, cement or dissolve. Because of the fact that pyrex glass is not affected thermally or chemically by any of the methods commonly employed in sterilization, these standards can be sealed in ampules and autoclaved to prevent mold or bacterial growth which would interfere with their accuracy.

The Occurrence of Atmospheric Lead Resulting from Use of Colored Blackboard Crayons

HAROLD W. RUF, PH.D., AND WILLIAM Z. FLUCK

Industrial Hygiene Unit, State Board of Health, Madison, Wis.

THE Wisconsin State Board of Health was recently requested to analyze two samples of yellow blackboard crayons suspected of containing lead. The analysis showed they contained respectively 7.0 and 8.8 per cent lead. Subsequent discussions with school officials disclosed that yellow blackboard crayons were extensively used, especially in defective vision classes. The present tendency of substituting light colored writing surfaces for blackboard necessitates the exclusive use of colored crayons. The possibility of lead poisoning due to inhalation of lead dust produced while using some of the colored crayons became apparent and the problem seemed sufficiently important to warrant investigation. The investigation was divided into 3 portions, (a) evaluation of the lead content of crayons, (b) determination of the amount of crayon used under various classroom conditions, and (c) amount of lead present in the air when crayons containing lead pigment were used.

Twenty-seven crayons representing 6 different manufacturers were analyzed for their lead content. The crayons were obtained from various schools or school supply houses in Wisconsin without selection. Lead was determined

by electrolytic separation, interfering metals being eliminated in the procedure. The analytical results are given in Table I. Of the samples analyzed, lead was found only in the yellows, oranges, and greens, the quantity varying between 1.5 and 12.0 per cent by weight. These results are in accord with those reported by Jephcott.¹ One yellow crayon was submitted for analysis which contained no lead pigment, and information has been obtained that another manufacturer is developing a lead-free yellow crayon.

RATE OF CRAYON USAGE

Studies made in actual classrooms showed that the amount of crayon used varies considerably, depending on the type of work. In two of the grade school rooms visited, only 0.1 gram of crayon was used in each during the entire afternoon, while in one university class 7.9 gm. were used during a period of 1 hour. It seems reasonable to expect that where a number of students are doing board work, the amount of chalk used would exceed the maximum observed.

To obtain a crayon usage unit for subsequent experiments, the amounts of crayon used by 8 persons writing a standard sentence for a given time were

determined. The average was found to be 0.28 gm. per person per minute of actual writing, with a maximum of 0.58 and a minimum of 0.10 gm. Preliminary experiments also showed that for a given period of writing, the amount of crayon usage from a 5 gm. stick was approximately the same as from one having twice the density.

DUST EXPERIMENTS

The studies relative to the amount of crayon dust dispersed into the atmosphere were divided into two parts—those made in a room under controlled conditions and those made in actual classrooms.

Air samples were obtained with a Greenburg-Smith all glass impinger

using 5 per cent nitric acid solution as the collecting medium. The concentration of lead was determined by the dithizone method of Harrold, Meek, and Holden.²

The room used for the controlled experiments was 38 by 14 by 11½ ft. high and was provided with mechanical ventilation. The outlet grill was located to the right of and 6 ft. from the blackboard. Air entered the room through a door at the rear. Atmospheric samples were collected at two points, one adjacent to the blackboard at the breathing zone of the individual writing and the other in the center of the room at a height corresponding to the breathing level of students.

The variable factors in the controlled

tests were crayon used during a given time and the amount of ventilation provided. Crayon usage was varied between 1 and 10 gm. per ½ hr. period. During Series A, the amount of air removed was approximately 1½ cu. ft. per min. per sq. ft. of floor area, and during Series B, ¼ cu. ft. per sq. ft. of floor area.

The data from the controlled experiments are given in Table II. The air samples were collected during two periods, Periods I and II. During Period I, previously weighed amounts of yellow crayon containing 6.8 per cent lead were used in periodic writing for 30 minutes. Air samples were collected adjacent to the blackboard and in the center of the room throughout the period. Immediately following Period I, a second set of air samples was collected for 30 minutes (Period II) at the same locations. No writing or erasing was done during this period. In

some cases, a third set of samples was collected beginning 70 minutes after writing had ceased and continuing for 30 minutes.

The data in Table II show that when using 6.8 per cent lead crayons, the concentration of lead in the air may at times exceed the 1½ mg. of lead per 10 cu.m. of air recommended by the U. S. Public Health Service as the maximum amount permissible for prolonged exposure. The data further show that during the writing period, the amount of lead at the breathing zone of the person writing is dependent on the rate of crayon usage. During the writing period the lead was dispersed throughout the room air, but in all cases the concentration was below that at the blackboard. The maximum concentration of lead found in the samples collected 70 minutes after writing ceased was 0.2 mg. per 10 cu.m. of air.

The second group of tests was con-

ducted in 3 classrooms A, B, and C. Due to the noise created by operation of the impinger apparatus, it was not feasible to collect air samples while the classes were in progress. Runs No. 1, 2, and 4 were made immediately after class had been dismissed. The remaining 6 runs were made in classrooms where no classes were in progress.

Classroom A was 74 by 13 by 11½ ft. high, and Classroom B, 20 by 15 by 10¾ ft. high. Neither of these rooms was provided with mechanical ventilation, the only ventilation being that occurring naturally through doors and windows. To vary conditions in room B, the doors and windows were open to different degrees, thereby simulating conditions as existing during winter, spring, and summer. Room C was 29 by 26 by 15 ft. and was provided with mechanical ventilation.

Data from this series of tests are given in Table III. The results were in agreement with those of the controlled group in that ordinarily the

concentration of lead in the air at the center of the room was below 1.5 mg. per 10 cu.m. of air. However, under adverse conditions it seems reasonable to expect that higher concentrations of lead may occur. During Run 9, in which 13 gm. of crayon were used in 1 hour's writing, the concentration of lead in the air at the blackboard was 5.9 mg. per 10 cu.m. During Run 7, the concentration of lead at the center of the room was 1.3 mg. of lead per 10 cu.m. of air. Thirteen gm. of 8.0 per cent lead crayon were used prior to Run 7, and 17 gm. during the run. The quantity of crayon appears to be high but on the basis of data obtained from actual crayon usage, indications are that conditions would be comparable to a class of 15 students each writing 7 minutes out of 2 hours.

Individuals subjected to the greatest lead exposure are teachers and students writing at the boards, and janitors cleaning boards, erasers, and classrooms.

When it is considered that children

appear to be more susceptible to lead intoxication than adults, the desirability of replacing lead chromate as a pigment is apparent. In addition to the possibility of lead absorption by inhalation, the danger of ingestion by nibbling pieces of crayon as pointed out by Jephcott should not be ignored. The fact that at least one manufacturer has produced a yellow crayon free of lead shows that the hazard can be eliminated.

SUMMARY AND CONCLUSIONS

1. Of the 27 samples of blackboard crayons analyzed, lead was found to be present only in various shades of yellow, orange, and green. The maximum quantity of lead found

was equivalent to 12 per cent by weight.

2. One sample of yellow blackboard crayon contained no lead.

3. Where colored crayons containing appreciable quantities of lead are used, the concentration of lead in the classroom atmospheres may exceed the toxic limit of 1.5 mg. per 10 cu.m. of air as determined by the U. S. Public Health Service.

4. In view of the potential health hazard involved in the use of lead as a pigment in colored crayons, this material should be replaced by one which is non-toxic.

TUBERCULOUS INFECTION DUE TO MILK

WHILE the danger to human beings from bovine tuberculosis is now universally recognized, very seldom have what might be called acute epidemics of tuberculosis been recorded, and still more rarely has the outbreak been traced to a single cow with recent tuberculosis of the udder. Hence the outbreak in Sweden recently reported¹ is of more than usual interest and emphasizes the necessity of vigilance.

In August and September of 1936, in the village and municipality of Horred, Sweden, several children showed tuberculous symptoms for which no human source of infection could be found. By the middle of October, 30 cases had been recorded. Altogether, 56 infected persons were discovered of whom 9 were from 13 to 64 years of age. Among 102 children who did not consume milk from the tuberculous cow there were only 8 positive reactors, while of 32 who were known to have consumed this milk, 29 were positive. Of 29 children under school age, 11 who did not take any of the infected milk all gave a negative reaction, while of 18 who drank the milk, 16 gave a positive reaction. Since 1935 all inhabitants of Horred except those who had their own cows, have been obliged to drink the milk from the Horred dairy. Pasteurized milk was objected to on account of its boiled taste so that the milk for drinking purposes was consumed raw.

A striking point is that the herd was one which since 1935 had been attached to the State subsidized organization for the prevention of tuberculosis in cattle. It had been physically examined in May, 1935, when one cow was taken out on account of tuberculosis. Another examination was made in May, 1936, when no tuberculous animals were discovered. In September, 1936, a third clinical examination was made and at that time samples of milk from the 22 animals of the herd were taken for bacteriological examination. One cow showed clinical mastitis but tuberculosis was not suspected. However, her milk was found to contain many tubercle bacilli demonstrable on centrifugation and staining. This cow was slaughtered at once. Post-mortem examination showed recent tuberculosis, mostly in the right lung and pleura. There were diffuse peritoneal

deposits and a number of mesenteric glands were enlarged and showed caseous foci. The left half of the udder was enlarged and hard, and numerous tuberculous foci were found.

It is plain that milk from a cow with active tuberculosis of the udder was consumed by most of those children who developed tuberculosis, while others who did not drink this milk escaped. There is no statement that tubercle bacilli were isolated from these children and proved to be bovine, though the history justifies this conclusion.

It is clear that clinical examination of cattle to detect tuberculosis is not to be wholly depended upon. This herd was under a State organization whose object was the prevention of tuberculosis in cattle in an infectious form. Presumably more than common care was given to this herd. Apparently the veterinary inspection was done by competent men, yet not until a number of children became ill was it suspected that the herd contained an animal excreting tubercle bacilli in its milk.

The second lesson is that tuberculin tests of cattle supplying milk for market purposes should be made at regular intervals. The third lesson, and perhaps most important, is that all milk for drinking purposes should be pasteurized.

In view of this history it is surprising that the Swedish Parliament in 1938 passed an act regulating the sale of milk and cream for human consumption under which exemption may be granted from compulsory pasteurization of milk not only from cows which do not react to tuberculin, but also from those which have passed a clinical examination. It is clear that under such exemption the users of the milk are not entirely safe, as this tragic outbreak demonstrated. Again the necessity of pasteurization has been shown in a striking manner.

A NEW NAME FOR DRY MILK SOLIDS

NEARLY a quarter of a century ago, when skim milk usually was regarded as a waste product, definitions for "skim" or "skimmed" milk and "dried skimmed milk" were adopted by the federal government and most of the states. These official names and definitions usually have remained unchanged to the present day, although the conditions of use and the nutritional appreciation of these products have greatly changed.

In recent times, the so-called dried skimmed milk has become an important article of commerce, and significant as an actual and potential contributor to human nutrition, as well as to animal feeding.

While pasteurized or certified whole milk is properly recognized as our most nearly perfect food, much of its food value is actually below the cream line. Removing the butterfat from whole milk may take away this source of food-energy and the vitamins, A and D, associated with it, but there remain practically all of the valuable minerals, proteins, lactose, and other vitamins of the original milk.

When these important non-fat milk solids are dried, the resulting product is a concentrated and inexpensive source of the food-minerals, calcium and phosphorus, and of milk proteins, milk sugar, and certain vitamins. Dry milk

solids are rich in vitamin B₂ (riboflavin) and represent a good source of vitamin B₁ (thiamin), as well as of other components in the vitamin B complex.

The most extensive modern use of dry milk solids of this type is in the baking industry, which now purchases about 100,000,000 pounds annually for inclusion in white bread and cake. The growth of this desirable use of milk solids in bread is indicated by the fact that in 1923 less than one-third of this quantity was obtained by bakers. Dry milk solids are also widely employed in the making of confectionery, in certain meat products, and in various other food industries.

Because of the present wide use of dry milk solids and the unfortunate connotations of the words "skim" or "skimmed" in the public mind, it has been suggested that official designations of this product be changed from "dried skimmed milk" to "dry milk solids not over 1½ per cent fat," a definition which already has been adopted in two or three states. Since this terminology would permit of accurate and truthful labelling of a wholesome product, and would tend to remove the popular misconception about the real value of skimmed milk, the proposed new definition seems reasonable and deserves favorable consideration.

ADVANCE IN FOOD HANDLING

IT is well inside of the truth to say that one of the great problems of the world today is—as it always has been—food. With increasing populations the carry over from the season of plenty—in other words, the preservation of foodstuffs—has grown in importance. The scientific student of nutrition has investigated what happens to foods during the processes necessary. Are their wholesome qualities preserved, destroyed or impaired? The commercial food purveyor has been quick to recognize the scientific aspect. Extensive laboratories are maintained, staffed by outstanding experts provided with every facility for the best work. Volumes are pouring forth on almost every aspect of nutrition but not enough has been told the public about the practical aspects of food preservation. The advances made in handling and preserving foods are fully as notable as the scientific discoveries concerning the foods and equally as necessary for good results. In a very few years we have advanced from the wooden container to stainless steel, which now holds the stage as the best material so far discovered for use in plants devoted to the preparation of foods. It also is largely used in kitchens and pantries on ships as well as on land. It finds wide use for cutting and serving tables and containers for keeping foods hot in eating places for which it is particularly good since foods may be kept for any length of time without damage or change. Breweries are adopting it for storage and for transportation, while piping is largely employed for service in bars.

After many experiments it has been found that a low-carbon steel (0.1 per cent) to which 18 per cent of chromium and 8 per cent of nickel is added is most satisfactory, having a high corrosion-resistance, yet being remarkably ductile and workable. Sheets and plates of such composition can be rolled and bent to shape, are suitable for press work, deep-drawing (milk and ice cream cans, for instance), can be welded by any of the several methods, except hammering, to form smooth and homogeneous joints which can be readily polished. This is important as the material exhibits its best corrosion resisting properties when the surface is free from films or scales. It is amenable to brazing, hard or soft soldering, etc., but these processes are not recommended these days in milk or food plants.

No metals except the noble ones have such a wide range of resistance as stainless steel. It is not attacked by any of the ordinary foods or food acids and as a consequence does not give off to the foods dissolved metal, hence their flavor, color keeping qualities, etc., are not changed. It is very tough and resistant to wear and tear, scratching and distortion, points of importance in the consideration of new installations, since the greatly prolonged life compensates for the higher first cost. The expense of maintaining a clean and hygienic plant is reduced to a minimum. Hot caustic soda does not affect it at all, so can be used for washing without fear of damage. It is the same throughout its mass, not depending on a metallic coating of veneer, consequently there is nothing to peel or wear away.

Certain brines employed in cooling systems, notably calcium chloride brine, are liable, under certain conditions, to pit the steel. This feature has been taken care of by incorporating into the 18 chromium-8 nickel type of stainless steel from 0.5 to 1 per cent of silver, which forms "on the exposed surface of the steel a continuous self-healing film of a silver compound originating from silver which is intra-granularly included in the steel."¹

So far the milk industry is one of the largest users of stainless steel equipment. In many new plants it is specified throughout. In this country the so-called glass-lined tank is still used for rail transportation over long distances. In England milk is carried to central depots from the farm in "churns" where it is transferred to stainless steel tanks, mixed in other tanks of this material, then pumped into insulated stainless steel rail tank wagons for transportation. In the great city plants the pasteurizers, holders, cooling tanks, filling machines, and bottle platforms are all of stainless steel. In the newest plants for the production of milk powder stainless steel is used throughout.

The increasing use of stainless steel in all the various types of food handling, preservation, preparation, and serving, especially in public places, is to be welcomed as marking a distinct advance from the public health point of view as well as from that of the manufacturer.

BOOKS AND REPORTS

Medicine in Modern Society—By *David Riesman*. Princeton, N. J.: *Princeton University Press*, 1938. 226 pp. Price, \$2.50.

Based upon his rich experience as professor of clinical medicine and of medical history, Dr. Riesman here presents a thoughtful interpretation of medicine addressed primarily to intelligent laymen. The purpose of the work is clearly implied in the question posed at the start: "Is it not just as important for the cultured man to know something of the history of the circulation of the blood, of vaccination, of anesthesia . . . as it is to know the story of the Punic Wars . . . ?" It is a sad fact that history, as taught in the schools, still largely omits the vital story of science in general and of medicine in particular, and Dr. Riesman here shows how effectively this theme can be and should be developed.

The book begins with a historical survey which emphasizes the medical progress of the 19th and 20th centuries. The discussion of recent developments in such fields as allergy and nutrition is clear and specific, so that the lay reader will find in it not only cultural background, but also information valuable for his own health. There then follow a number of chapters on special topics, such as cancer, the neuroses, and healing cults. These also are presented in a simple yet authoritative manner. Something of the wisdom of a tolerant medical philosopher creeps into all of these essays. Indeed, it is the blending of scientific with human understanding—of science and art—which affords one of the chief charms of the whole work.

The final sections are addressed to

the medical profession as well as to the laity, and contain chapters on medical education, ethics, and the social outlook. In dealing with the difficult and controversial questions involved in "socialized medicine," Dr. Riesman naturally displays a full appreciation of the great services which the medical profession has afforded society, and notes the importance of protecting this group against any changes which would limit its real usefulness. He also faces squarely the lack of medical service available to certain classes, and the consequent need for some type of professional organization to meet this need. Certain of the usual objections made to various plans for "social medicine" he finds untenable; and his final conclusion is that some form of health insurance for the middle classes, under the control of the organized profession, offers the best way out of present difficulties. All in all, this is a most sane and thoughtful book, the sort of work which should be made a part of the training of all well educated citizens.

RICHARD H. SHRYOCK

The Treatment of Clinical and Laboratory Data. An Introduction to Statistical Ideas for Medical and Dental Workers—By *Professor Donald Mainland*. Edinburgh: *Oliver & Boyd, Ltd.*, 1938. 340 pp. Price, \$4.50.

The author is a professor of anatomy at Dalhousie University who, in the course of his work, became impressed with the importance of modern statistical methods, and, having searched out such methods for himself, undertakes in this book to give laboratory and clinical workers the benefit of his

findings. The viewpoint and technics advanced in the book follow closely those of R. A. Fisher, thus providing another example of the immense influence that Professor Fisher continues to wield on the newer recruits to the art of statistics. Very largely the book concerns itself with tests for "significance," by which one can "make adequate allowance for chance in all observations." It gently but firmly castigates medical and dental investigators for neglecting consideration of chance variation, and opines that they have therefore frequently gone astray in their conclusions. The reviewer cannot, from his own experience, conscientiously agree that so many casualties are attributable to this particular weakness, but there can be no doubt that good quantitative work should take account of "chance" variability.

In the one illustration of the fallacies which result from the neglect of statistical tests elaborated by the author, we side with the writer criticised. The occasion for criticism is a report on the effectiveness of serum treatment in mitigating paralysis or death during an epidemic of poliomyelitis. The report found a significant difference in the percentage of cases untowardly affected in the treated and untreated groups, but, self-critically, the report said, "A criticism may be raised. Are not the more favorable results observed in the serum-treated cases due to the fact that they are milder cases . . . ? We may answer it from several different angles. . . . Following Draper's view that a cell count in the spinal fluid of over 100 indicates a serious type of disease, a comparison of the cell counts in treated cases and controls shows no appreciable difference in numerical incidence of the counts, from which it would follow that there is no significant difference in the average severity of the two groups of cases." It is this argument in the re-

port that the author criticises. He says, "Now it is possible from the report to test the association between cell count and severity of disease. The table on p. 81 quotes numbers of cases in each instance. In neither set of cases is there a significant association between cell count and severity of the disease; therefore it is not permissible to use the cell count as a criterion of severity in the cases under investigation."

Why is it not permissible? The authors of the report did not in the first place rest their use of the cell count as an index of severity on their own investigation, which had another purpose, but on Draper's, and unless evidence is adduced which casts doubt on the validity of Draper's work, there is nothing relevant here. Do the data obtained by the author from the report and presented as a table (p. 81) refute the conclusion of Draper that there is a correlation between severity of disease and cell count? On the contrary, we find on examining the table that it confirms Draper throughout! In the non-treated group as well as the treated group, the rate of incidence of death or paralysis is considerably greater in the patients with high cell counts. On what then did the criticism of the author rest? Apparently on the fact that the difference between the incidence in the high and low cell count groups was not "significant" in the technical sense that the chi-square P did not reach some arbitrary low level.* But this would be relevant only if the report were trying to prove from its own observations that cell count was correlated with severity of disease. Actually the report rested this con-

* For the experience as a whole, this reviewer finds that the difference in incidence between the high and low cell count groups is +16 per cent, and the probability of such a difference on the assumption of chance variation alone is 0.04. Such a small P would be, for some statisticians, enough evidence to indicate a correlation even if there was no other evidence available!

clusion on Draper's work, not the present investigation, and it does not appear clear to us how the confirmatory findings in the investigation, even though if taken alone they would not be considered sufficient to *establish* the correlation, should be held to cast *doubt* on the correlation previously found.

There are arguments in other parts of the book which similarly overstress the importance of a "P" found from some statistical test, to the exclusion of what appears to us as more important considerations. However, enough has been said to indicate why, in the opinion of this reviewer, though a medical or dental worker will find much that is interesting and useful in this book, it will be hazardous for him to accept it as the last word.

JOSEPH BERKSON

Alcohol in Moderation and Excess
—By J. A. Waddell, M.D., and H. B. Haag, M.D. *Richmond, Va.: William Byrd Press, 1938. 184 pp. Price, \$1.00.*

The General Assembly of Virginia in 1936 adopted a resolution requesting the University of Virginia and the Medical College of Virginia to provide a report on "The effects of the use of alcohol upon the human system in respect to both moderate and excessive use thereof." In consequence, a report was prepared by two professors, one in each of the two institutions named, with the collaboration of six other faculty members. The report was prepared primarily as a source book for school teachers rather than as a text.

When the General Assembly met in 1938 the manuscript was referred to the Senate with the expectation that it would be printed as a Senate document. Prior to the convening of the General Assembly, however, a summary of the report had been made public, and a protest was made by the dry

organizations of the state against the printing of the document. It was not printed by the Senate. Later the House ordered that the report be printed, so its members might read it, but the protest of the "drys" was again effective; all copies were ordered burned.

Subsequent to the rejection of the report by the Assembly, the manuscript and copyright privileges were returned to the authors and the book was published commercially. The material in the present edition is the same as that used in the edition burned.

The book first provides material on the properties of alcohol and certain pertinent physiological data. It then deals with the effect of alcohol on the central nervous system, and, somewhat less fully, with its effects on the respiratory, circulatory, and digestive systems.

According to the authors, much of the information on the effect of alcohol is in a state of flux and so, unfortunately, many vital questions still remain debatable. The authors have endeavored to cull reasonably conservative deductions from the studies at hand, and the volume seems to deserve the opinion of the Virginia State Board of Education which describes it as a most valuable contribution, scientifically sound and very scholarly.

REGINALD M. ATWATER.

Educating for Health: A Study of Programs for Adults—By Frank Ernest Hill. *New York: American Association for Adult Education, 1939. 224 pp. Price, \$1.25.*

One of a series of studies in the social significance of adult education in the United States, this book describes the work of important organizations engaged in teaching American men and women to lead healthier lives. "Health education is carried on by such a multitude of public and private agencies," states the foreword, "and is so varied

in character, that it forbids a thorough treatment in a single volume."

This volume aims to give an over-all view of what is being done, indicating interrelationships, trends, and problems. The material was gathered from visits to a dozen states, many cities and counties, by a careful, critical but apparently sympathetic observer, who was primarily concerned with health education not as an aspect of health work but as a form of teaching and learning. The author has done a constructive job and rendered a valuable service from which public health educators and administrators may derive benefit.

IRA V. HISCOCK

Health for 7,500,000 People—
Annual Report of the Department of Health, City of New York, for 1937, and a Review of Developments from 1934 to 1938. New York: Department of Health, 1939. 390 pp.

This volume is more than an annual report; it is a well written review of the administrative and physical development of the Department of Health of our largest city during the 4 year period 1934 to 1938. Attractively bound and printed, with numerous charts and photographs, its informal style and simplicity of presentation insure its readability, not only to technical workers in the field, but to the public at large.

Departmental activities are outlined in four sections, the administrative section, the medical, nursing and bacteriological section, the sanitary section and the vital statistics section. Under those wide headings separate services are discussed in short chapters. Perhaps the most interesting of these is that dealing with development of the neighborhood health work. Although plans had been worked out previous to the beginning of the period under review, only one of the 30 districts into which the city had been divided had

been supplied with a health officer. In 1934 the positive initiation of the program began with the appointment of administrative staffs for seven districts. The beginning of 1938 found 13 civil service district health officers appointed as well as 7 medical officers-in-charge assigned to district work. Nine new health centers had been built and a tenth building remodeled for this purpose.

Other chapters describe the anti-syphilis campaign, reorganized tuberculosis work, pneumonia program, personnel training program, modernization of the bureaus responsible for supervision of food supplies and environmental hygiene, and the work carried on in the new William Hallock Park Laboratory. One chapter is given to the place and use of federal grants in the health program.

The vital statistics section of the report adequately presents the main features of natality, infant and maternal mortality, and mortality in general. Standardized death rates are available by cause as well as rates by sex, color and age. In addition a number of repository tables have been included which give detailed data on trends of the principal causes of death and the sex and age distribution of deaths by cause.

J. H. WATKINS

Vitamins and Vitamin Deficiencies—
By Leslie J. Harris, Ph.D., Sc.D. Philadelphia: Blakiston's, 1938. 204 pp. Price, \$2.50.

This is the first volume of a series to be published under the general title of Vitamins and Vitamin Deficiencies. This volume is entitled Vitamin B₁ and Beri-beri—Introductory and Historical.

This is a very interesting little book. The author states that his aim has been to provide a "comprehensive synopsis." He has done this.

An enormous amount of research is reviewed but there is no attempt to

give detailed information on any point; an excellent bibliography accompanies each chapter. There are a good many illustrations which add greatly to the value of the book. Pictures of 8 outstanding pioneers in the study of vitamins are given: Lind, Takaki, Eijkman, Grijns, Holst, Hopkins, Funk, and McCollum.

The following sentence taken from the Foreword by Sir F. Gowland Hopkins is a fitting close to this brief review:

I can strongly recommend the book to all students who desire acquaintance with the present position and outlook in the field of vitamins, and believe that the specialist will welcome an admirable summary of the facts available to-day and a bibliography fully up to date.

NINA SIMMONDS

Macmillan's Modern Dictionary
—*Edited by Bruce Overton. New York: Macmillan, 1938. 1466 pp. Price, \$3.00, with thumb index, \$3.50.*

The "Modern Dictionary" must be an efficient guide to the choice and in the use of words; it must be concise and compact, yet comprehensive in compass; it must excite the interest of the user and intrigue him to the study of words as living things; and it must by and of itself help in the development of the dictionary habit."

This excellent objective has been attained to an unusual degree. The Editor has given us something really new in dictionaries.

At first one misses the appendixes, tables of various sorts, lists of foreign words, pronouncing gazetteer, abbreviations and signs used in writing and printing, thermometric scales, etc., so often found. Macmillan's uses "one vocabulary that is peculiar to this dictionary," and in alphabetical order one finds a wealth of biographical sketches, geographical names, foreign words and phrases, and indeed information on practically every subject that one can

desire. An unusual number of idiomatic phrases are given. Slang is treated kindly in recognition of the growing character of our language, but is properly labelled as such. Many colloquialisms are given.

A decided departure is the omission of illustrations. The editor believes that they have been used to embellish the pages rather than to clarify definitions, and points out that great areas of knowledge such as mathematics, philosophy, psychology, theology, sociology, and other department of human intelligence, although contributing a much larger vocabulary, are scantily illustrated.

The only practical way to judge a dictionary is to use it day by day. By this test the reviewer has found it modern in every respect, easy to use, well printed and helpful. A curious omission is the word "pyrology," the derivation of which seems plain, but for which there seems to be little agreement as to definition. The *Scientific Monthly* for June, 1939, uses the word to mean the "science or technology of fire control."

Macmillan's can be recommended to those for whom it is designed—businessman, speaker, writer, general reader or student. MAZÏCK P. RAVENEL

Getting Ready To Be a Father—
By Hazel Corbin. New York: Macmillan, 1939. 48 pp. Price, \$1.25.

This little volume is so interestingly written, effectively illustrated and printed, that one is likely to read it through at one sitting and wish that every man who is "expecting a baby" might have a copy to profit by the experience of George Halladay, the hero of this story. Here is contained useful information given in classes for prospective fathers dealing with maternity care from the father's point of view, selection of hospitals, physicians and nursing care, guides in meeting the physical

and psychological problems to be faced by both parents, expenses, and suggestions for fitting the baby into the home, even to making furniture and equipment which will facilitate the care of the baby in congested quarters.

IRA V. HISCOCK

Water Supply Engineering—By *Harold E. Babbitt and James J. Doland.* (3rd ed.) New York: McGraw-Hill, 1939. 690 pp. Price, \$6.00.

In any rapidly advancing field of effort having the scope of water supply engineering, it is difficult to keep a textbook current and still not exceed a useful and convenient size. This third edition by Babbitt and Doland seems to have surmounted this difficulty.

Containing 635 pages of text and averaging almost 1 figure to every 2 pages, it covers water works finances, hydraulics; rainfall runoff and consumption; ground and surface waters with methods and devices for developing and purifying them for consumer use; the relations between water quality and diseases; and an interpretation of numerous analytical procedures available today.

As a textbook, it must necessarily be complete. This forces brief treatment of subject matter but notwithstanding that, this new volume fulfils its purpose adequately and well.

ARTHUR P. MILLER

Population, Race, and Eugenics—By *Morris Siegel, M.D.* Hamilton, Ont., Can.: The author, 546 Barton St., East, 1939. 206 pp. Price, \$3.00.

This is a good discussion of the problems of race and eugenics for the lay reader. It treats these problems simply and clearly. It is not over-dogmatic nor is it as biased as is often the case when the occasional writer tackles general questions of this kind. It can be heartily recommended to the general reader who would like to get a

bird's-eye view of the eugenic situation.

The word "Population" in the title gives the impression that it treats of population questions, aside from "Race" and "Eugenics," more than it actually does, but this does not constitute a serious defect considering the purpose of the book and the public it is intended to reach.

A little more careful proof-reading would have helped it in places.

WARREN S. THOMPSON

A Textbook of Applied Microbiology and Pathology—By *Thurman Rice, A.M., M.D.* (2nd ed.) New York: Macmillan, 1939. 271 pp. Price, \$2.50.

The only important change made in the second edition of this very practical and usable text for student nurses is the inclusion of a section on General Pathology.

The material on Bacteriology has not been shortened—in fact, it appears in almost the exact form given in the first edition. By condensing the size of the type and omitting a few illustrations the actual number of pages remains the same even though approximately one-sixth of the second edition is given over to the section on Pathology, which covers, after an introduction, Congenital Abnormalities, Neoplasms, Progressive and Retrogressive Changes in Tissues, Inflammation, Circulatory System, and Circulatory Disturbance.

This additional material is presented in the same simple and interesting style which characterizes the older sections. It is not complete enough to serve as a text in a course in General Pathology, but it does supply fundamental knowledge of disease and fulfil the purpose for which it was intended. The usefulness of this added section will largely depend upon the organization of the course for which the book is used.

The drawings have been made by the

author. In most cases they are exaggerated as to size in order to emphasize special features.

The book will continue to hold its high place among texts of this type.

ANNA DEAN DULANEY

Class Fertility Trends in England and Wales, 1876-1934—By *John W. Innes*. Princeton, N. J.: Princeton University Press, 1938. 145 pp. Price, \$2.50.

That there exist wide differences in fertility between different social and economic classes in the population has been noted by nearly all population students since the time of Malthus. It has also often been noted that the decline of birth rates during the past half century or more seems to have widened these differences. The matter of larger families among the poor than among the more fortunate social classes, has long been of concern to both eugenicists and to some sociologists. Recently, however, there have been accumulating scattered bits of evidence which suggest the hypothesis that such fertility differences may be temporary phenomena and that the future may see a closing of the gap between the birth rates of different occupational and social classes. Some students of population are even predicting the complete disappearance of fertility differentials within the next few decades. It was to test this hypothesis of "democratization" of birth rates that the present research was undertaken.

The first part of Dr. Innes's study consists of a careful re-analysis of fertility rates by occupational classes for England and Wales. The data are drawn from the Census Report of 1911 on the Fertility of Marriage in England and Wales by the late T. H. C. Stevenson. The results of this analysis seem to point rather clearly to the conclusion that the sharp decline

in fertility which seems to have begun about 1876, proceeded at quite different rates for different occupational groups. This divergence in fertility trends for different social classes continued unabated up to the turn of the century, so that by 1900 fertility rates were both absolutely and relatively further apart than they were 25 years before that time.

In the second part of his study, the author attempts to pursue the analysis of class incidence of fertility decline beyond the period for which the report of 1911 supplies the data. Since later census reports do not provide material which is comparable with that found in the earlier report he was forced to have recourse to another approach and method. To study class differentials in fertility beyond 1911, use is made of fertility data for different boroughs and districts of metropolitan London classified into "class-areas" on the basis of socio-economic criteria. If we may accept London area-class fertility rates as comparable with English occupational class fertility rates, then the pattern of class differentials has been quite different since 1900 as compared with the earlier period. Already by 1911 the lead in the decline of the birth rate had passed from those classes of highest socio-economic status to those lower in the scale. By 1934 all fertility differences between the three higher classes had been obliterated, and the differential between classes I and IV had been reduced to an insignificant amount. Class V, that with the lowest social and economic rating, continued to retain the position of highest fertility, but the absolute difference between it and the other classes had greatly diminished and its downward fertility trend relatively had kept pace with the trends of other classes. Between 1931 and 1934 the sharpest decline in fertility was found in class V.

It would indeed be foolhardy to con-

clude from the results of this and a few other similar studies that differences in class fertility will disappear within the near future. The author warns against drawing any such conclusions even for London, to say nothing of all England and Wales. It may not be too much to say, however, that the study does give us reason to discount the alarms of the eugenists in their concern over the future quality of the population as a result of differential birth rates. Certainly the evidence presented in this study does not seem to indicate that lack of "prudence and foresight" is reproducing a special "social problem" class in the population.

Dr. Innes has made an important contribution to the literature on differential fertility. While the lack of comparable data may preclude the possibility of repetition of his methods in other countries, his study should stimulate researches elsewhere for the testing of the hypothesis of the "democratization" of the birth rate.

C. T. PIHLBLAD

The Health of College Students—
By Harold S. Diehl, M.D., and Charles E. Shepard, M.D. Washington: American Council on Education, 1939. 160 pp. Price, \$1.50.

This book is a report by the authors to the American Youth Commission of the American Council on Education. It is a study of 4,800 young people and 500 institutions of higher learning. Through the CCC the Council obtained data on a large number of young men from the lower economic backgrounds. The result is a most interesting book, giving what we believe to be the most comprehensive study yet made of the population of this class and age.

It opens with a general consideration of the health of youth, goes on to give the development of college health work, discusses the problems, programs, and organization of such services, and ends

with Suggestions for Organization and Development of College Student Health Service. Three appendices give statistical tables, forms used in study, and a list of the colleges and universities which participated.

The work has been carefully done under competent direction and contains a wealth of material of great value. It is open to the criticism that a great deal of the material was obtained through questionnaires, and allowance must be made for the human disposition to present a good appearance.

The report can be thoroughly recommended to all interested in this great question and should find a place in every university and college library. The printing and binding are excellent.

MAZŮCK P. RAVENEL

Nursing Through the Years—*By Corrine Johnson Kern. New York: Dutton, 1939. 340 pp. Price, \$2.50.*

The story has its beginning in the operating room of a well known San Francisco hospital as Corinne Johnson, the author, is on duty for the last time as a student nurse. The next day she is to start private practice, she has thoroughly enjoyed her student days and wonders if she will be successful and happy in her chosen life's work.

In the spring of 1900, she was employed as office assistant to Martha Purdy, M.D., who was lovable, queer yet the most tactfully impertinent human being imaginable. The doctor's life was filled with purposeful undertakings—births, surgery and medical care—the days were not long enough to care for her busy practice in that remote country town.

Her next assignment was in a country home near the Pacific Ocean. At first the attending physician was disappointed to find that a young nurse weighing only ninety pounds was sent in answer to his request, but he was more than delighted with her capable

handling of a family situation which resulted in his patient's rapid recovery.

Interwoven with the personal account of caring for patients in all walks of life from the homes of the uneducated and poor to homes of refinement and of the very wealthy, is the story of the progress in the fields of medicine and nursing.

Corrine Johnson won the respect of all with whom she associated; her happy, pleasing personality brought encouragement and hope as well as qualified nursing service to each one.

She retired to her mountain bungalow to rest but found that her chosen career of nursing suffering humanity was to keep her busy, so she continued to answer their calls any hour of the day or night.

The story is simply and sincerely told and will interest lay readers as well as professional members.

MARGARET STRONG

Man and His Health—*New York: Exposition Publications, Inc., 1939.* 96 pp. Price, \$.50.

The American Public Health Association has a special interest in the Medical and Public Health Exhibits at the New York World's Fair. In the late 1920's planning for an exhibit of this sort began. In 1931 a committee was appointed, and when the World's Fair was announced in 1935 this committee saw its opportunity and succeeded in interesting the Fair Corporation so that one of the most interesting exhibits at the World's Fair is in the Medicine and Public Health Building which contains the Hall of Medical Science and the Hall of Man. The exhibits are the result of the combined efforts of nearly 1,000 individuals.

The Hall of Man was designed to house the original Oberlaender Trust Collection of exhibits on anatomy and physiology. It was developed and sponsored by the American Museum of

Health. The exhibit is to satisfy Man's natural curiosity about himself, to introduce Man to Man himself. Here the anatomy and physiology of the body is illustrated, showing how man breathes, walks, digests his food, how his senses operate, and how he reproduces himself. It contains a Transparent Man of life size, showing the relation of the skeleton and organs of the body. A remarkable series of models has been developed for this purpose.

In the Hall of Medical Science are many exhibits of interest to everyone, only some of which can be mentioned, but enough to show the range of subjects of wide general interest which they cover: Maternal Health, Child Health, Normal Growth and Development, Veterinary Medicine and Public Health, Medical Education, Housing for Health, Syphilis, Infections, Immunity, and Heart and Circulation of the Blood. These have been sponsored by voluntary associations, such as the American Medical Association, American Public Health Association, American Social Hygiene Association, American Veterinary Medical Association, etc., as well as by some foundations, and a certain number of commercial firms interested in public health and the manufacture of medicinal preparations.

Each one of these exhibits is under an Exhibit Committee made up largely of persons interested in the special lines to which the exhibit refers.

The American Museum of Health, incorporated as a nonprofit educational institution under the laws of the State of New York, was created in December, 1937, and makes its debut at the New York World's Fair. Even before its dedication, June 17, more than 1,750,000 had examined the displays which it contains. The interest shown has exceeded all expectations. The day-to-day attendance runs more than a third of the paid admissions to the Fair.

The American Museum of Health has created and acquired most of the important and durable exhibits now on view in the Medicine and Public Health Building. At the conclusion of the Fair it is planned to move these exhibits to a permanent institution for visual health teaching in the City of New York. Coöperation in securing a building for the purpose has been assured.

MAZÛCK P. RAVENEL

The Comparative Values of Chest Roentgenograms Made on Film and on Paper for Industrial Surveys—*Medical Series, Bulletin No. II. Pittsburgh: Air Hygiene Foundation of America, Inc., 1939. 20 pp., 7 charts in pocket.*

This study was directed by Dr. E. P. Pendergrass of the Hospital Department of Radiology, University of Pennsylvania, while the technical aspects were developed by the staff of the Moore School X-ray Laboratory. Several leading X-ray companies and film manufacturers coöperated in the project. Of special interest, 49 roentgenologists in eastern and middle western states examined the roentgenograms and recorded their opinions in special questionnaires.

The *Bulletin* discusses The Physical Characteristics of Roentgenograms on X-ray Film and X-ray Paper, Preliminary Experimental Procedure, Roentgenographic Exposure Techniques, Test Roentgenograms and Questionnaires, Physical Data of Test Roentgenograms, Roentgenologists' Comments on Test Roentgenograms, and Conclusions.

While, as has been found before, the average density and contrast of roentgenograms made on paper are inferior to those on film and the former should not be used in place of the latter unless for important practical reasons, nevertheless, if a large group of employees are to be examined by

single roentgenograms, the use of paper in rolls is less expensive, quicker, and available for survey work, if the technical methods here outlined are used, with provision for pathological and doubtful cases to be referred for more thorough radiological examination.

Thirty-one of the 49 roentgenologists were of the opinion that the paper roentgenograms would be satisfactory for a preliminary survey. Certain improvements in the technical procedures with paper roentgenograms can be made. The authors believe that since the paper roentgenograms are in no way superior to those on film, it would be best in the long run to attempt to work out a scheme for making roentgenograms on film quickly and at low cost, possibly by using X-ray film in rolls. Decreasing the size of the roentgenograms would also reduce the cost.

In particular, it would be extremely useful to devise a detailed specification of all the technical factors involved in making chest roentgenograms which might be accurately followed thereafter in any laboratory.

The *Bulletin* is necessarily quite technical, and in some places not very clear in language, while considerable basic knowledge of roentgenography and photography is assumed.

EMERY R. HAYHURST

Education of the Handicapped—*By Merle E. Frampton and Hugh Grant Rowell. Vol. I, History. Yonkers-on-Hudson, N. Y.: World Book Company, 1938. 200 pp. Price, \$2.40.*

The chief virtue of this volume seems to be that it has gathered between its two covers a mass of miscellaneous information concerning the history of care for those handicapped in vision, hearing, speech, mental or social development, and for the crippled and

those "under vitalized" through tuberculosis, heart disease, or malnutrition. Such a compilation fulfils a long felt need and this volume will be welcomed by teachers and lecturers in several fields.

Certain details of the attitudes toward each of the handicapped groups, of the development of specific educational methods for each group, and of the leaders in those movements which have helped or hindered each are recorded.

The authors emphasize how much the handicapped have depended upon the development of social and humanitarian movements and how any progress in their education has *followed* rather than *led* the cultured and scientific patterns through the ages. They conclude that because of the complex nature of needs of these specialized groups this must continue to be so.

A second premise is that the history of these groups has been influenced more by great personages than by social, economic, religious, or political events and, therefore, with the exception of the socially handicapped, the general pattern of telling of the lives and influence of various figures prominent in the history of each group has been followed. This results at times in a succession of names and events in which the theme of the story seems to be only faintly heard. Would it not have been possible to tell as integrated a story for the visually handicapped, for example as Sanford Bates has written on the socially handicapped.

The volume has been edited and apparently largely written by Drs. Framton and Rowell. Distinguished contributors are listed, though credit is given only to Bates in the chapter on the socially handicapped and to Romaine Prior for the chapter on the orthopedically crippled. A bibliography of important books and magazine articles on each subject is included—

but the text itself is not documented.

For the public health worker, the volume presents a broad point of view on the subject of the handicapped; one emphasizing the need for and possibility of assisting these persons to live effectively in the world as they find it. To include the cardiacs as well as the blind in the picture is helpful. The story of the former is limited—but the discussion of open air classes is certainly pertinent. No mention is made of other medically handicapped, the asthmatics, for example.

LEONA BAUMGARTNER

Fighting for Life—By S. Josephine Baker, M.D. New York: Macmillan, 1939. 246 pp. Price, \$2.75.

This is the autobiography of one who has gloried in fighting for good causes. Dr. Baker tells of a day when she was 6 years old and all dressed up for some great occasion. She wore a "beautiful white lacy dress with a blue sash and light blue stockings and light blue shoes." As she sat on a horse block contemplating her fine appearance, a little black girl happened to come along, looking peaked and hungry and attired in rags. Thereupon Josephine took off all her own clothing, even her underclothes, and gave them to the poor colored child, returning to her home quite naked. This action Dr. Baker describes as characteristic of herself through life. She says she has always been trying to do things about hopeless situations.

Happily, most of Dr. Baker's struggles ended in victories. Her experience as a pioneer in obtaining medical training for women, and as a militant leader in the suffragist movement, and, above all, her notable career in the New York City Department of Health where she became head of the Bureau of Child Hygiene, are told with detail and zest. The names of many prominent members of the

medical profession, the stage and political life, and scenes and incidents relating to New York, particularly in the nineties and early part of the present century, adorn the pages. The keen enjoyment which seems to have been taken in writing the book is certain to be shared by readers.

It is unfortunate that this entertaining book is marred by a number of inaccuracies. Two examples will suffice.

Dr. Baker's early home was in Poughkeepsie, where she lived until she was 16 years of age. She left, following the death of her father from typhoid fever. The prevalence of the disease that winter, she says, led to the installation of the first municipal water filtration plant in the United States. The truth is that the Poughkeepsie filter was built in 1872 from designs by James P. Kirkwood. If Dr. Baker was 16 then, she must be 83 now, an imputation which she would probably resent.

The discovery of Typhoid Mary is described, but quite incorrectly. Dr. Baker was at the time an inspector in the New York City Health Department and succeeded in arresting the woman with the help of four policemen, after she had been located and her pugnacious character explained. Contrary to Dr. Baker's account the investigation which led to the arrest was not made in order to test any statement of Robert Koch's, nor was it made by anybody connected with the New York City Department of Health, nor any other health department, for that matter. Nor was the arrest made to see whether the investigator's* suspicions were justified. The case had been fully proved by him before it was brought to the attention of the city health department. The effect of Dr. Baker's statement is not only to rob the investigator of much of the credit

which properly belongs to him, but gives what seems to be authority to an erroneous account of what has long been regarded as a most important epidemiological discovery. GEORGE A. SOPER

Pulmonary Tuberculosis in Adults and Children—By James Alexander Miller, M.D., and Arvid Wallgren, M.D. New York: Nelson, 1939. 193 pp. Price, \$3.50.

The authors have republished in book form, with some modification, their articles in the *Nelson Loose-Leaf Medicine*. Both authors recognize the extreme complexity of tuberculosis and the multiplicity of factors which may determine the course of the disease. Miller classifies pulmonary tuberculosis as primary, prephthisical and phthisical. Wallgren as primary, secondary and tertiary, thus following German and French terminology rather than that commonly used in the United States. They feel that these groupings help clarify the pathogenesis of the disease and bring into proper relief the hematogenous spread of the bacilli in the body. Both are critical of the American emphasis on exogenous reinfection, since they feel it to be of minor importance, hence they do not approve of the classification of Primary Tuberculosis and Reinfection Tuberculosis adopted in the 1938 Edition of *Diagnostic Standards*, published by the National Tuberculosis Association. It is the reviewer's understanding, however, that this classification, as explained in *Diagnostic Standards*, has met with very little adverse criticism in this country. Until the reasons for the protean nature of tuberculosis are known with more certainty it is doubtful whether further refinements in classification will have value clinically.

It is natural that the authors, holding the views indicated, do not stress the protection of infected persons from contact with open cases. Indeed,

* George A. Soper (Editor).

Wallgren goes so far as to say "it is generally found that children who are tuberculin-positive do not run any risk if they are exposed to tuberculous infection." This is, of course, opposed to the view of tuberculosis specialists and public health workers in this country.

Wallgren discusses in an interesting way erythema nodosum and sero-fibrinous pleurisy, both of which appear to be more frequent in Sweden than in the United States, and writes out of wide experience of the prognostic aid of repeated sedimentation tests. He states that the demonstration of tubercle bacilli in the gastric lavage water "has no prognostic significance nor does it offer any guidance in treatment or in judging the contagiousness of the child."

Some of the reproductions of X-ray films do not show clearly the pathology indicated in the text. Few typographical errors were noted. On page 37 and again on page 58 the sentence following (3) beginning "the first intercostal spaces between the clavicles" presumably should read "below" instead of "between." At the top of page 153 column 1 "a manner of chance" should read "a matter of chance." Wallgren's rather extensive references are mostly to continental European writers.

For an interesting presentation of the pathogenesis of tuberculosis the book is to be recommended. For details of treatment, especially collapse therapy, other authors dealing comprehensively with therapy should be consulted.

JOHN H. KORN

Nutrition—By Margaret S. Chaney, Ph.D., and Margaret Ahlborn, M.S. (rev. ed.) Boston: Houghton Mifflin, 1939. 436 pp. Price, \$3.00.

This text has been substantially rewritten since the first edition, published 5 years ago, but the original form has been retained.

Nutrition deals with the health of the individual as related to food and the ability of the body to utilize food. Pre-parental education, as that given, should aid considerably in correcting bad food habits and in the promotion of an optimal state of health in the members of the family. Some mention is made of the relationship of food to certain pathological conditions in which diet is of primary importance.

There are 14 excellent chapters discussing energy metabolism, minerals, vitamins, body regulators, nutrition during the reproductive period, and optimal nutrition for infants, children, and adults. Recent developments are presented and an up-to-date bibliography is appended to each chapter. The text is supplemented by 56 fine illustrations and 85 tables. The appendix contains many excellent food value tables, height-weight charts, and other similar data. Its unique value lies in its presentation of an outline of methods for animal experimentation applicable to vitamin testing. This section includes methods for feeding and breeding stock animals; assaying for vitamins A, B₁, C, D, and riboflavin; anemia testing; and methods for the preparation of constituents of experimental diets. Detailed directions are also given for the use of the Benedict-Roth recording metabolism apparatus.

Nutrition is a well organized book whose authors have overcome some of the failings of similar texts. It deserves a place in the reference library of doctors, nurses, dieticians, and other nutritionists.

C. R. FELLERS AND A. S. LEVINE

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Telling the Public—So many of your well read lay contacts will have discovered this excellent dissertation on chemotherapy with sulfanilamide and its derivatives, that you had better prepare yourself to discuss the matter by reading the article, too. Once more *Fortune* does an outstanding job in public health education.

ANON. Cure by Chemicals. *Fortune*. 20, 3:42 (Sept.), 1939.

Health Education by Doing—In Syracuse (New York) the juniors and seniors in public and parochial high schools are offered the tuberculin test and X-ray examination if positive: about half accept the test, but all learn about tuberculosis. Four years ago a third were positive reactors; today less than a quarter. Discussants suggest that where the tuberculosis rate is low and, as in Syracuse, where community case finding is adequate, justification for school testing may depend upon cost per diagnosis.

AYLING, W. E. The Value of Tuberculin Skin Tests in a School Program. *New York State J. Med.* 39, 15:1463 (Aug. 1), 1939.

Historical Note—Some interesting historical highlights on the evolution from law enforcement to health guidance are told in a brief radio talk by one who took an active part during the whole period. Not many of us can quote what he heard Koch say to Biggs.

BOLDUAN, C. F. Education versus Compulsion. *New York State J. Med.* 39, 15:1505 (Aug. 1), 1939.

All about Colds and Related Ills—Here, you will find a good workman-like review, brief and to the point, of everything you will need to use in

telling your public about the respiratory infections and related conditions. It is a continued story and both parts should be read and saved.

CECIL, R. L. The Control of Respiratory Infections. *Preventive Medicine* (New York Academy of Medicine). 9, 3:50 (June), 1939.

Quaranto Die—Discrepancies between established facts about communicability of certain diseases and the control measures adopted by the Canadian provinces (which in many instances are not as incongruous as our own) appear to the public as evidence of blundering and inconsistency. Health departments may well experiment but there should be better international and interstate agreement in practices.

EMERSON, H. Current Practice in Communicable Disease Control. (and) JENKINS, R. B. The Value of Present Control Measures in Communicable Diseases. *Canad. Pub. Health J.* 30, 7:325 (July), 1939.

Putting the Bacterium in His Place—Useful definitions of some badly abused words—disinfection, sterilization, bacteriostasis—introduce a discussion of practical disinfection methods available for the public health nurse working under the handicaps of the usual home. It's to be continued.

FROBISHER, M. Disinfection in the Home. *Am. J. Nurs.* 39, 8:833 (Aug.), 1939.

Some Slips Twixt Cup and Lip—The time has come, the author says, for health and water works officials to give more consideration to what happens to the water in public systems en route to the consumer in order to minimize health hazards that now exist. What these hazards are and

what to do about them are the subjects of the useful paper.

GORMAN, A. E. Potential Health Hazards in Distribution of Water. *J. Am. Water Works A.* 31, 7:1143 (July), 1939.

Limitless Possibilities of Isotypes

—Some information about Neurath's methods that all health educators, in name or in fact, will want to store away for future use.

KAEMPFERT, W. Facts March On—with Neurath. *Survey Graphic.* 28, 9:538 (Sept.), 1939.

Just as One Would Assume—

Nutritionists will appreciate this exact study, the findings of which are that bone development in the wrist is related to the diet of the child. Youngsters on an institutional diet supplemented with reconstituted evaporated milk or with cod liver oil made better bone growth than those who received no supplements.

MACNAIR, V. Effect of a Dietary Supplement on Ossification of the Bones of the Wrist in Institutional Children. *Am. J. Dis. Child.* 58, 2:295 (Aug.), 1939.

Cancer Statistics—This is a significant finding: cancer of the digestive tract which causes about half the male deaths and a third of the female deaths from cancer, makes up only a quarter of all lesions in living cases. In the case of cancer of the breast and uterus the rates are about the same in living and fatal cases. Cancer of the skin and lip are the most frequent sites among males, whereas cancer of the breast and genital tract are most common among females.

MOUNTIN, J. W., *et al.* The Incidence of Cancer in Atlanta, Ga., and Surrounding Counties. *Pub. Health Rep.* 54, 28:1255 (July 14), 1939.

Has Today's Tuberculous Patient a Better Chance?—Some pretty gloomy statistics about the success of tuberculosis treatment have been pub-

lished recently and annotated in these pages. Now we can report something on the brighter side. The fatality rate has been steadily reduced at Trudeau Sanatorium, and early diagnosis by means of the roentgenogram has played an important part in the decline.

SAMPSON, H. L. Fatality Rates in Pulmonary Tuberculosis. *Am. Rev. Tuberc.* 40, 1:71 (July), 1939.

Let Us Flee Said the Fly, etc.—

Here is something you probably do not know: most insecticides used for spraying rooms are toxic and irritating to the skin in sufficient concentration. Both the petroleum distillate and the active principle usually are irritating but no notice to this effect is given. Users should be warned and the directions should urge the use of protective clothing, the exposure of the skin as little as possible, and that containers be kept away from children.

SCHWARTZ, L., and WARREN, L. H. Dermatitis Caused by a New Insecticide. *Pub. Health Rep.* 54, 31:1426 (Aug. 4), 1939.

Overweight and High Blood

Pressure—In a large group of physical examinees, especially among those from 50 to 59, overweight was found to increase the incidence of hypertension. The incidence, however, was not as great as some other observers have reported.

SHORT, J. J., and JOHNSON, H. J. An Evaluation of the Influence of Overweight on Blood Pressures of Healthy Men. *Am. J. M. Sc.* 198, 2:220 (Aug.), 1939.

Health Officers and Medical Care

—If the public provision of adequate medical care is to come, as this author believes it will, then the established health departments should administer it. If the decade following 1940 is to be a period of accomplishment as the 30's were of discussion, then public health had better set its house in order.

SINAI, N. The Present Situation Regarding the Adequacy of Medical Care in the

United States. *Canad. Pub. Health J.* 30, 7:319 (July), 1939.

Among Our Blessings—At least one worry that is not likely soon to plague American sanitarians is given a

thorough airing for the benefit of our British brethren. The title tells the story sufficiently for our purposes.

WILLIAMSON, A. B. *The Problem of the Disposal of the Dead after Air Raids.* *Pub. Health.* 52, 11:329 (Aug.), 1939.

ASSOCIATION NEWS

SIXTY-EIGHTH ANNUAL MEETING

Pittsburgh, Pa., October 17-20, 1939

HEADQUARTERS — HOTEL WILLIAM PENN

CALENDAR OF THE 68TH ANNUAL MEETING

Sunday, October 15

- 9:00 A.M. Registration begins (Ball Room, William Penn Hotel).
- 9:30 A.M. Collegiate Council on Public Health Nursing—National Organization for Public Health Nursing.
- 10:00 A.M. Sixth Institute on Public Health Education opens.
- 2:30 P.M. Health Education Institute.
Collegiate Council on Public Health Nursing—National Organization for Public Health Nursing.
- 8:30 P.M. Community Mass Meeting—
American Social Hygiene Association.

Monday, October 16

- 9:30 A.M. Pittsburgh Breakfast—under the auspices of the Women's Entertainment Committee. Everybody invited.
- Association of Women in Public Health.
- Conference of Municipal Public Health Engineers.
- Conference of State Laboratory Directors.
- Conference of State Sanitary Engineers.
- International Society of Medical Health Officers.
- Health Education Institute.
- State Directors of Public Health Nursing.
- Education Committee—National Organization for Public Health Nursing.

Luncheons.

- Association of Women in Public Health.
- International Society of Medical Health Officers and Health Education Institute.

- 2:30 P.M. American School Health Association.
- Conference of Municipal Public Health Engineers.
- Conference of State Laboratory Directors.
- Conference of State Sanitary Engineers.
- International Society of Medical Health Officers.
- Education Committee—National Organization for Public Health Nursing.
- State Directors of Public Health Nursing.
- Health Education Institute.
- 4:00 P.M. Conference of Directors of Local Health Service.
- 4:30 P.M. Tea—Association of Women in Public Health.
- Dinners. International Society of Medical Health Officers.
- National Organization for Public Health Nursing.

Tuesday, October 17

- 9:15 A.M. Health Education Institute.
Section Meetings.
- 2:30 P.M. Section Meetings.
- 8:30 P.M. Opening General Session.

Wednesday, October 18

- 9:15 A.M. Section Meetings.
- 11:45 A.M. General Session—Professional Education.
- 2:30 P.M. Section Meetings.
General Session—Medical Care.
Conference on Health Museums.
- 6:30 P.M. Pennsylvania Public Health Association and Tri-State Food and Health Officials Dinner.
- 8:30 P.M. Public Meeting.

Thursday, October 19

- 9:15 A.M. Section Meetings.
- 11:45 A.M. General Session—Cancer.
- 2:00 P.M. Sight-seeing Trip.
- 7:00 P.M. Annual Banquet.

Friday, October 20

- 9:15 A.M. Section Meetings.
- 2:30 P.M. Section Meetings.
- 5:00 P.M. Adjournment.
- Late Evening. Departure of special trains for New York for delegates attending the New York World's Fair.

Saturday, October 21

NATIONAL HEALTH DAY at the New York World's Fair.

The abbreviated calendar above omits breakfast, luncheon and dinner sessions of sections, committees, and special groups. It also omits mention of many conferences of interest to limited numbers of delegates. No reference is made to the important and varied inspection trips. The final program, obtainable at the Registration Desk in the Ball Room of the William Penn Hotel, will convey full information about all these things.

Hotel and railroad rates have been published in the *Journal* as have also the summary of the scientific sessions and descriptions of places of public health interest in Pittsburgh which delegates will visit. Consult the July, August, and September issues. Come to Pittsburgh for the 68th Annual Meeting of your Association and meetings of related organizations.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- George W. Bassow, M.D., Main St., Woodstock, N. Y., Health Officer
- Edwin H. Federman, M.D., Court House Annex, Eau Claire, Wis., City-County Health Officer
- German Figueroa, M.D., C.P.H., Ayacucho 166, Barquisimeto, Venezuela, S. A., Health Officer
- Erwin F. Hoffman, M.D., M.S.P.H., 805 Vulcan St., Iron Mountain, Mich., Director, Dickinson County Health Dept.
- Joseph A. Johnson, M.D., Box 58, Greensboro, Ga., Commissioner of Health, Greene County Health Dept.
- Raymond Luft, M.D., 1915 Elmwood Ave., Norwood, R. I., Superintendent of Health, City of Warwick
- Harcourt A. Morgan, Jr., M.D., Athens, Tenn., Director, McMinn County Health Unit
- Charles F. Nassau, M.D., LL.D., Sc.D., 503 City Hall Annex, Philadelphia, Pa., Director, Dept. of Health
- Frederick P. Perkins, M.D., Capitol Annex, Room 103, Phoenix, Ariz., Superintendent of Public Health of Arizona
- James E. Peterman, M.D., 624 Church St., Indiana, Pa., District Medical Health Officer
- L. L. Sanford, M.D., University of Wyoming, Laramie, Wyo., Director of Student Health and University Physician

Maurice D. Vest, M.D., M.P.H., 619 Carson Ave., La Junta, Colo., Health Officer, Otero County Health Unit

Laboratory Section

- F. W. Janssen, 109 Grand St., Hoboken, N. J., Director of Laboratories, Janssen Dairy Corp.
- Dr. Francesco N. Piccaluga, Blandengues 4350, Buenos Aires, Argentine, S. A., Director, Instituto Massone
- Fries Shaffner, B.S. in Ed., 486 Avalon Rd., Winston-Salem, N. C., Serologist, Forsyth County Health Dept.
- Jennie S. Siemienski, B.A., M.T., 10036 Jos. Campau, Hamtramck, Mich., Medical Technologist, Dept. of Health

Public Health Engineering Section

- Melvin A. Dobbs, B.S. in C.E., 325 East Broadway, East St. Louis, Ill., Sanitary Engineer, East Side Health District
- Curtis B. Williams, B.S., State Dept. of Public Health, Santa Fe, N. Mex., State Milk Sanitarian

Child Hygiene Section

- Evelyn F. Buchheim, M.D., 682 Jean St., Oakland, Calif., Pediatrician, Bureau of Child Hygiene, State Health Dept.
- Grace L. Dowell, R.N., 111 N. 3rd St., Arkansas City, Kans., Health Supervisor, Public Schools
- Anita E. Faverman, M.D., 1838 Anza St.,

San Francisco, Calif., Pediatrician, State Health Dept.

Melvin J. H. Tess, M.D., 14th and Market Sts., Municipal Courts Bldg., St. Louis, Mo., Supervisor, Parochial School Health Program, Health Dept.

Industrial Hygiene Section

Marion F. Trice, B.S., 2004 Stone St., Raleigh, N. C., Industrial Hygienist, State Board of Health

Food and Nutrition Section

William V. Cruess, Ph.D., 339 Hilgard Hall, University of California, Berkeley, Calif., Assistant Professor in Food Technology

Public Health Education Section

Eleanore Aldworth, M.A., 2116 Devonshire Road, Ann Arbor, Mich., Hygiene Instructor, State Teachers College

Eva M. Bourne, R.N., 200 N. Michigan St., Roswell, N. Mex., City School Nurse

Paul Dodds, M.D., Room 510, South Office Bldg., State Capitol, Harrisburg, Pa., Director, Bureau of Maternal and Child Health, State Health Dept.

Donald A. Dukelow, M.D., 3744 46th Ave. S., Minneapolis, Minn., Director of Public Health Education, State Health Dept.

Alice L. Edwards, A.B., 306 State Bldg., Civic Center, San Francisco, Calif., Public Information Editor, State Health Dept.

Elizabeth C. Hoover, M.D., 1432 Potomac Ave., Dormont, Pa., Physician, Board of Health

Florence C. Kahn, D.H., 306 State Bldg., San Francisco, Calif., Dental Hygienist, State Health Dept.

Eloise Kloss, B.A., City Health Dept., Louisville, Ky., Director of Health Education

Meyer J. Plishner, B.S., M.P.H., Mill and Passaic Sts., Paterson, N. J., Public Relations Secretary, Passaic County Tuberculosis and Health Assn.

Ruth F. Rogers, B.A., Michigan Dept. of Health, Lansing, Mich., Consultant in Dental Health

Margaret M. Twombly, A.M., 1681 Shasta Ave., San Jose, Calif., Acting Head, Dept. of Health and Hygiene, San Jose State College

Public Health Nursing Section

Anna R. Ballo, 616 S. Third St., Raton, N. Mex., Colfax County Health Nurse

Jefferson I. Brown, R.N., State Board of Health, Phoenix, Ariz., Chief Nursing Consultant

Verna E. Hancock, Argonaut Hotel, Denver, Colo., General Field Supervisor, State Health Dept.

Winifred Humber, R.N., B.S., P. O. Box 233, Lone Pine, Calif., Public Health Nurse, Division of Child Hygiene, State Health Dept.

Sister Minalia, B.S. in Ed., R.N., St. Elizabeth Hospital, 49 Hopeland St., Dayton, Ohio, Director of Nurses

Marjorie J. D. McLean, 112 Riverside Ave., Decorah, Iowa, School Nurse, Board of Education

Catherine A. Sullivan, R.N., 318 S. 4th St., Steubenville, Ohio, City Health Nurse

Bessie Tattershall, R.N., 69 Main St., Tuckahoe, N. Y., Staff Nurse, Public Health Nursing Organization of Eastchester

Helen M. Wolfe, 305 State Bldg., San Francisco, Calif., Consultant in Orthopedic Nursing, State Health Dept.

Frances H. Ziegler, B.S., R.N., Vanderbilt University, Nashville, Tenn., Dean, School of Nursing

Epidemiology Section

John A. Carswell, M.D., D.P.H., P. O. Box 2658, Juneau, Alaska, Epidemiologist, Dept. of Health

Richard J. Kettering, City Health Office, Aberdeen, S. D., Milk Sanitarian

Charles H. Mann, Jr., M.D., M.S.P.H., 301 N. Erie St., Bay City, Mich., Assistant, Division of Hygiene and Public Health, University of Michigan

James M. Mather, M.D., D.P.H., 19 Grand St., Coldwater, Mich., Assistant to Branch County Health Director

Unaffiliated

R. H. Lucas, 925 Main St., Columbia, S. C., Accountant, State Board of Health

Frances A. Macdonald, A.B., 236 Bay State Road, Boston, Mass., Junior Epidemiologist, State Dept. of Health

Cyrus H. Maxwell, M.D., 3 Winding Road, Elmsmere, N. Y., Chief, Health Service Bureau, State Education Dept.

Charles E. McBrayer, M.D. (Lieut. Col. U.S.A., Retired), Hotel Multnomah, Portland, Ore.

Galina Mouromseff, B.A., 219 Montclair Ave., Montclair, N. J., Research Dept., Westinghouse Electric and Manufacturing Co.

Lucy V. Reardon, M.A., National Institute of Health, Washington, D. C., Associate Protozoölogist

APPLICANTS FOR FELLOWSHIP

(Additional to names published in August and September *Journals*)

In accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Eligibility, and the Governing Council will take place between now and the time of the Pittsburgh Annual Meeting.

Health Officers Section

- William H. Best, M.D., Deputy Commissioner,
New York City Dept. of Health, New
York, N. Y.
Regnar M. Sorenson, M.D., C.P.H., Director,
Division of Venereal Disease Control, State
Dept. of Health, Des Moines, Iowa
Maysil M. Williams, M.D., C.P.H., State
Health Officer, Bismarck, N. D.

Laboratory Section

- N. Paul Hudson, M.D., Ph.D., Professor and
Chairman, Dept. of Bacteriology, Ohio
State University, Columbus, Ohio
Murrell O. Robinson, V.M.D., Professor of
Bacteriology, Alabama Polytechnic Insti-
tute, Auburn, Ala.
Fred D. Stimpert, Ph.D., Medical Micro-
biologist, Los Angeles County Hospital,
Los Angeles, Calif.

Public Health Engineering Section

- Milton H. Bidwell, B.S., Bacteriologist, New
York State Conservation Dept., Oceanside,
L. I., N. Y.
Francis M. Dawson, M.C.E., Dean, College
of Engineering, University of Iowa, Iowa
City, Iowa

Industrial Hygiene Section

- Edward G. Meiter, Ph.D., Director, Indus-
trial Hygiene Laboratory, Employers Mut-
tual Liability Insurance Co., Milwaukee,
Wis.

Food and Nutrition Section

- Frederic W. Nordsieck, S.B., Associate, Dept.
of Nutrition, American Institute of Baking,
New York, N. Y.

Child Hygiene Section

- Francis V. Corrigan, M.D., Chief, Division
of Maternal and Child Health, State Dept.
of Health, Providence, R. I.

Public Health Education Section

- Harold S. Diehl, M.D., Sc.D., Dean of Med-
ical Sciences, University of Minnesota,
Minneapolis, Minn.

Bess Exton, M.A., C.P.H., Assistant Health
Educator, National Education Assoc.,
Washington, D. C.

D. Clare Gates, Dr.P.H., M.S.P.H., Director
of Health Education, State Dept. of Health,
Bismarck, N. D.

Ruth E. Grout, C.P.H., Ph.D., Senior Super-
visor of Health Education, Dept. of
Health and Safety, Tennessee Valley
Authority, Chattanooga, Tenn.

Leo H. Mynes, M.D., Medical Director,
Kanawha County School Health Service,
Charleston, W. Va.

Delbert Oberteuffer, Ph.D., Professor of
Physical Education and Chairman, Division
for Men, Ohio State University, Columbus,
Ohio

Anna B. Towse, B.S., Executive Secretary,
Good Teeth Council for Children, Inc.,
Chicago, Ill.

Margaret H. Tracy, A.B., Executive Secre-
tary, Boston Health League, Boston, Mass.

David B. Treat, A.M., Director of Public
Health Education, Dept. of Public Health,
Flint, Mich.

Kathleen W. Wootten, M.A., Head, Health
Dept., Georgia State College for Women,
Milledgeville, Ga.

Epidemiology Section

Harold W. Brown, M.D., Dr.P.H., Professor
of Public Health, University of North
Carolina, Chapel Hill, N. C.

Bernard M. Blum, M.D., M.P.H., Assistant
District State Health Officer, State Dept.
of Health, Buffalo, N. Y.

Unaffiliated

Robert P. Fischelis, Phar.D., B.Sc., Secretary
and Chief Chemist, Board of Pharmacy of
the State of New Jersey, Trenton, N. J.

Marie C. Harrington, M.A., Educational
Director, Dairy Council of St. Louis, St.
Louis, Mo.

Bruce H. Pollock, M.D., C.P.H., District
Health Officer, State Dept. of Health, Point
Pleasant, W. Va.

THE WESTERN BRANCH REPORTS ON TEN YEARS OF PROGRESS

FROM the Western Branch of the A.P.H.A. comes an interesting and illuminating report of ten years of progress as recorded by Dr. William P. Shepard who retired as Secretary of the Western Branch at its Oakland meeting in July. Dr. Shepard pays tribute for remarkable progress to the vigorous and courageous national leadership in the Public Health Service, and to the principles for which the American Public Health Association and the Western Branch have always stood, namely, an abiding faith in the importance and values of the public health cause and a willingness to work together for public health advancement regardless of personal glory.

The Western Branch has reached its Tenth Annual Meeting with a membership of 1,437. Of this number 127 are Fellows and 871 active members of the A.P.H.A., and 439 are regional members. In 10 years the A.P.H.A. membership in the Western Branch has increased from 368 to 998—an increase of over 170 per cent! It is interesting to note also that the A.P.H.A. constituency in the Western Branch represents 15 per cent of the total A.P.H.A. membership. Since the last Branch meeting there has been a gain of 197 members, and not one state, province, or territory shows a loss in membership.

In 1929 when the Branch was organized, only 34 counties in its territory had full-time units. Today there are 64 counties with full-time health units and 75 more counties served by full-time health districts—a total of 139. Similarly, in 1929 there were 220 full-time employees engaged in health service in 32 counties (excluding Los Angeles and San Francisco). This year there are 825 full-time and 46 part-time public health workers engaged in the 137 counties. Ten years

ago there were 293 full-time employees in the 11 state health departments comprising Western Branch territory. This year there are 513, an increase of 220 or 75 per cent. Combining state and county full-time personnel, there were 513 in 1929, and in 1939 there are 1,338, an increase of 825 or 161 per cent. Unfortunately figures for the Provinces of Canada, the cities and Territories of the Western Branch are not available but there can be no doubt that here too the story would be as encouraging.

The influence of western public health workers in the affairs of the parent body is evidenced by the fact that today Western Branch members hold 53 A.P.H.A. offices or committee memberships. In 1930, at the time of the First Annual Meeting there were 30 such incumbents. The interest of Western Branch members in national health affairs is further evidenced by the yearly increase in their attendance at A.P.H.A. Annual Meetings.

When the Western Branch was organized, there was one Western state public health society affiliated with the A.P.H.A. Today there are 6 with an application pending from one state and another expected shortly.

Canadian members of the A.P.H.A. have been most enthusiastic in their support of the Western Branch and faithful in their attendance at its meetings. The Canadian membership has increased from 7 to 31.

The only two remaining Territories of the United States are included in the Western Branch. Through the efforts of the late Dr. F. E. Trotter, the membership in Hawaii has increased from 0 to 31. Dr. W. W. Council of Alaska is responsible for the increase in Alaska from 0 to 22.

Direct public health activities of the

Western Branch are a matter of record. They loom large when the scientific papers presented at annual meetings, the minutes, committee reports, and resolutions are surveyed. Among them are:

Early recognition of the health hazards connected with the construction of Boulder Dam and recommendation to the proper persons that these be given careful study. The health record of this enormous undertaking was surprisingly good, and the importance of preventive medicine in industry was once more demonstrated.

Repeated pleas for national assistance with the health problems of migratory workers, especially with tuberculosis. Only in recent years have these pleas been heeded.

Recognizing the value and helping to stabilize research in the control of Rocky Mountain Spotted Fever. Attention has been directed to the general prevalence of the disease, its eastward spread, and the necessity of ample supplies of vaccine. The Laboratory at Hamilton, Mont., has been assumed by the U. S. Public Health Service, additional buildings provided, and the staff increased.

Attention of state and national legislators has been repeatedly called to the importance of maintaining adequate funds for health protection and for providing trained personnel.

Urging the establishment of a western training school for public health personnel. Three years ago such a school was established at the University of California. Nearly 50 health officers have been trained as well as over 100 other individuals.

Public recognition in 1935 of the fact that plague infection was widespread among various rodents of the West. Immediate and intensive study was called for. The term "Sylvatic Plague" was introduced by Dr. Karl F. Meyer to distinguish this endemic wild rodent disease from epidemics of plague customarily associated with domestic rodents and man. Annual reports have been made and published since.

Appointment of a committee to promulgate and encourage newer methods of diagnosis and treatment of lobar pneumonia.

Equally interesting and important activities have been the discovery of "Valley Fever" and its relation to coccidioidal granuloma, and control of botulism and mussel poisoning. There are others too numerous to mention.

The original object of the Western Branch as stated in its Constitution is "to protect and promote public and personal health, and to promote better health service in the Western portions of the United States and the Dominion of Canada." In the 11 years of its existence the Western Branch has demonstrated its usefulness and the worthiness of this original object. The Western Branch has had virtually no money except a modest sum for limited mailing and printing from the parent organization. It has had no full-time personnel. Its work has been done by voluntary officers and committees.

The experiences recorded here have contributed to the success of this unique organization. They are made part of the record in order that they may not be lost sight of in the future.

CHARLES H. HOOD EDUCATIONAL TRUST

THE Charles H. Hood Educational Trust of Boston has made a grant of \$6,000 for the work of the American Public Health Association's Committee on Coördination in Health Education (Joint Committee between the Health Officers and Public Health Education Sections). Professor C. E. Turner of the Massachusetts Institute of Technology is Chairman.

The grant will be administered through the Health Education Research Laboratory at the Massachusetts Institute of Technology.

NEWS FROM THE SOUTHERN BRANCH

THE Southern Branch of the American Public Health Association will meet in Memphis, Tenn., during the annual sessions of the Southern Medical Association, November 21-24. The Branch meetings will be held on Tuesday and Wednesday, November 21-22.

Dr. P. E. Blackerby, Assistant State Health Commissioner of Kentucky, who is Secretary of the Southern Branch, has announced that with the approval of President J. N. Baker there have been made the following changes in the Governing Council and the Regional Executive Board of the Branch. Dr. James A. Hayne, Columbia, S. C., succeeds Dr. J. N. Baker as a member of the Regional Executive Board; and Dr. Felix J. Underwood, Jackson, Miss., is reappointed as a member of this Board. The following persons are also appointed to the

Governing Council of the Southern Branch: Dr. Warren F. Draper, District of Columbia; Dr. H. F. Parker, Jefferson City, Mo.; Dr. W. C. Williams, Nashville, Tenn., and Dr. I. C. Riggins, Richmond, Va.

SUBSCRIPTION AGENT IMPOSTER

IT has been reported that a WILLIAM DALTON has been offering cut rate prices in Texas on subscriptions to the *American Journal of Public Health*, *The Trained Nurse and Hospital Review*, *Modern Hospital*, and other publications. It is stated that he has collected money, giving receipts bearing the name "National Circulation Co., Inc., 343 N. Michigan Blvd., Chicago, Ill." Efforts to reach the National Circulation Company at this address have failed.

Members of the Association are again warned that no solicitors are employed by the *American Journal of Public Health*. Subscriptions should be placed direct with the Association office or through established subscription agencies.

DECEASED MEMBERS

- Ernest C. Dickson, M.D., San Francisco, Calif., Elected Member 1920, Elected Fellow 1934
- Lucius W. Holloman, M.D., Marksville, La., Elected Member 1936
- Lloyd A. Masterson, M.D., New Orleans, La., Elected Member 1936
- Wilbur A. McPhaul, M.D., Jacksonville, Fla., Elected Member 1936
- F. E. Trotter, M.D., Honolulu, Hawaii, Elected Member 1924

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, when keyed, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y., identifying clearly the key number on the envelope.

POSITIONS WANTED

HEALTH OFFICERS

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. **A355**

Experienced physician who has been local health officer and school physician in New York State, now has M.P.H. from Harvard School of Public Health, and wishes position in administration, epidemiology, or public medical service. **A423**

Physician, M.D., Yale; M.S. in field of public health, Columbia; also short course for health officers, Vanderbilt; good clinical background, 14 months' public health experience; will consider appointment in child health, epidemiology, or public health administration. **A350**

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; is available as venereal disease control officer. **A363**

Physician, experienced in health administration of cities and states, will consider attractive opening in maternal and child health or health education. **A343**

Physician, M.D., Vanderbilt University; Dr.P.H., Johns Hopkins; experienced as epidemiologist, health officer and professor of preventive medicine, seeks position as administrator or epidemiologist. **A397**

Physician, M.P.H., Harvard; well experienced in city and rural health administration, will consider appointment as district health officer or in city or state health department. **A418**

Well qualified physician, M.D., Rush; M.S.P.H., University of Michigan; with 3 years' residence in tuberculosis, and special interest in venereal disease control, seeks responsible appointment. Excellent references. **A406**

Physician, M.D., University of Cincinnati; M.P.H., Harvard; postgraduate studies in bacteriology and immunology. will consider position as health officer or epidemiologist. Has served as director of county health unit, director of industrial hygiene and medical statistics and venereal disease field survey officer. **A305**

Physician, aged 33; M.D., Minnesota; Dr.P.H., Johns Hopkins; has served as epidemiologist in large city and director of county health unit, with 7 years' public health experience; will consider position in public health administration or epidemiology. **A432**

Physician, M.D., Class A medical school; completed short course for health officers at Vanderbilt; experienced health officer and director of county health unit, will consider appointment as health officer or school physician. **A320**

Physician, M.D., Columbia; experienced as county health officer and superintendent of health, seeks position in public health administration or medical executive work. **A396**

Physician, M.D., Johns Hopkins; M.S.P.H., University of Michigan; experienced in school and city health work; for the past year director of county health department, seeks position as health director of city school system or in health service of a college or university. Will also consider position as epidemiologist or health officer in urban health department. **A354**

HEALTH EDUCATION

Young woman, experienced teacher in health education, with M.S. in Public Health and Hygiene from University of Michigan, seeks position as health coordinator. **H398**

Well qualified woman in health education wishes position as health coordinator or health counselor. Has wide experience, and Ph.D. from New York University. **H236**

Young woman, Ph.D., Columbia Uni-

versity, splendid background of experience in health education, will consider position as director of public health education. H294

Young woman, M.A., Health Education, Teachers College, Columbia; with splendid international experience, seeks position as director of health education. H369

Young man, M.S.P.H., University of Michigan, experienced in an eastern state department of health and as a university instructor, desires position in popular health instruction, especially by written media, with official or volunteer health agency or with commercial enterprise, insurance company or editorial work. H435

LABORATORY

Capable research worker, Ph.D., trained at University of Southern California and Pasteur Institute, seeks position directing laboratory, in research work or field investigation. Has taught bacteriology, directed state hygiene laboratory and hospital laboratories. L315

Broadly experienced laboratory director with excellent background, now employed southern state, seeks responsible position in laboratory work or teaching of bacteriology, immunology, or pathology. L426

Physician, C.P.H., Harvard-Technology; experienced as bacteriologist and pathologist and director of state laboratories, desires position. L208

Bacteriologist, M.S.P.H., University of Michigan; 2½ years as serologist in private hospital; desires work as serologist or bacteriologist in public health laboratory. Willing to start modestly. L425

Woman bacteriologist; B.A., Chemistry, 1933, 5 years' experience in experimental and practical therapeutics including animal work; desires position in public health field. L394

Young man bacteriologist, aged 33, with training in serology; for the past 4 years bacteriologist in charge, public health laboratory; will consider opening. L427

Chemist and bacteriologist experienced in water supply, sewage, and public health laboratory work. Five years' experience. B.S., 1933. Desires work in sanitation or general public health. L412

Chemist and bacteriologist, university graduate, M.A. and M.S., with 15 years'

experience in different phases of public health work, desires position. L438

Experienced woman bacteriologist, Ph.D., University of Illinois, 1937, wishes position in teaching or research. Excellent bibliography and references. L410

Young woman, registered medical technologist with 10 years' experience, specializing in the isolation of typhoid carriers, also trained and experienced in medical social work, desires position in public health laboratory. Prefers South. L438

MISCELLANEOUS

Physician, M.D., class A medical school; training in obstetrics and public health. Experienced as director of county health department, teacher of clinical obstetrics and administrator of state maternal and child health program, desires position in public health obstetrics or in maternal and child health administration. C417

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. M352

Experienced teacher in bacteriology and public health; Ph.D., Cornell; now professor in grade A medical school, will consider teaching, executive or administrative position. M327

Engineer with good training and experience in water treatment, sewage plant operation and in research, wishes position as superintendent. Can go anywhere. E422

Experienced director of milk control, food and sanitation and industrial hygiene. B.S. degree and well known record directing such work in two major cities and one state. References prominent public health personalities. I434

Engineer, sanitary inspector, lecturer, long experience in large city department of health, will undertake a new assignment in above fields or in administration. Warm climate preferred. M436

Physician, 32, married, M.D., 1936; postgraduate course in v.d. control, experienced as district health officer and in organizing and publicizing syphilis control campaign; now employed in charge venereal disease clinics in metropolitan health department; seeks v.d. control post with emphasis on organizational, investigative-survey or administration. M437

Situations Open

PUBLIC HEALTH PHYSICIAN—Young physician with good medical background, interested in obtaining public health training; salaried appointment at end of month in field; man of English, Irish or Scotch ancestry preferred. 100-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH PHYSICIAN—To be sponsored jointly by state department of health, Protestant mission; rural district; woman physician considered; \$2,700; South. 101-PH, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH PHYSICIANS—(a) Exclusive junior college for women; man or woman with Master's or Ph.D. degree, primarily trained internal medicine. (b) Co-educational college; man under 40 required; \$250 monthly, 11 months; Illinois. (c) Eastern university; recent graduate eligible; September-June; \$150. 102-PH, Medical Bureau, Palmolive Building, Chicago.

SCHOOL PHYSICIAN—Recent graduate contemplating public school health service as life work; duties include some teaching and dispensary service for students; eastern university; \$200. 103-PH, Medical Bureau, Palmolive Building, Chicago.

INDUSTRIAL NURSE—Registered nurse capable assuming complete charge industrial first-aid

station; southwest; \$150, maintenance. 104-PH, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH NURSE—Graduate nurse, trained public health work, for student health staff state normal school; 105-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—Graduate nurse with both public health and tuberculosis experience; busy tuberculosis follow-up service, city of 40,000; \$115, increasing, plus car allowance; North. 106-PH, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH NURSE—Duties largely general duty in infirmary exclusive college for women; 2 years' college training required; \$100, meals. 107-PH, Medical Bureau, Palmolive Building, Chicago.

ASSISTANT SCHOOL NURSE—Public school system, city of 10,000; graduate nurse trained for public health certificate required; \$1,100, nine months; midwest. 108-PH, Medical Bureau, Palmolive Building, Chicago.

LABORATORY TECHNICIAN—Preferably one with public health laboratory experience; should be exceptionally trained bacteriology and serology; excellent future for right person. 109-PH, Medical Bureau, Palmolive Building, Chicago.

Situations Wanted

PUBLIC HEALTH PHYSICIAN—A.B., mid-western college; M.D., Johns Hopkins; M.S.P.H., University of Michigan; interesting record of successful experience including long term as school physician in fashionable suburb; for further information, please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

BACTERIOLOGIST — B.A., eastern school; C.P.H. and Ph.D. (bacteriology), Yale University; has done considerable research; 4 years, bacteriologist and research technician, public health laboratories; desires appointment in public health laboratories; for further details please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

HEALTH EDUCATOR—A.B., Wellesley; M.S. in public health from state university; 6 years, teaching physiology and sciences in public schools; 2 years, director of child health education, national organization; 2 years, health counselor and teacher of health education, midwest metropolis; 4 years' social work; for further details, please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—Graduate of a fairly large training school of nursing; graduate training in public health nursing at the University of Minnesota; 10 years' experience as public school nurse; for further details, please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

1939 EDITION OF CONNECTICUT OFFICIAL MILK SEDIMENT STANDARDS

THE State Dairy and Food Commissioner and the State Commissioner of Health have approved the new 1939 Edition of the Connecticut Official Milk Sediment Standards. This standard is the only one acceptable and approved for use in laboratories making milk tests in Connecticut, and to obtain better uniformity of grading milk sediment it is urged it be used for sediment testing done in the field and at milk plants. The new standard has been specially adapted to field and plant use.

In the new edition the seldom used "Excessively Dirty" discs have been eliminated and the standard carries only three sediment discs which grade milk into four cleanliness ratings; namely, Clean, Good, Poor, and Dirty. The amounts of sediment on the pads of the new standard correspond roughly with sediment scores of 13, 50, and 100 on the 1931 Edition.

Public health laboratories in Connecticut approved for the examination of milk have been requested by the State Commissioner of Health to begin use of the 1939 Edition as soon as possible and instructed to have it in use not later than December 31, 1939. Notification has been sent out that the 1931 Edition should not be used after December 31, 1939.

For many years the Connecticut Official Milk Standard has been used extensively outside of Connecticut for the grading of milk both in the United States and in other countries. In *Standard Methods for the Examination of Dairy Products*, Seventh Edition, 1939, reference is made to photographic standards and those who do not wish to prepare their own discs are referred to the copies of the photo-

graphic standards prepared by the Connecticut State Department of Health Laboratory, Hartford. The report states:

The standards on this photograph are based on pint samples of milk to which weighed amounts of sediment have been added. The 1931 standards cover the range from clean to very dirty milk with numerical ratings or sediment scores given for each disc. The 1939 standards have been simplified by the elimination of cleanliness ratings for dirty milk.

Persons outside of Connecticut placing orders for milk sediment standards should state whether the new 1939 Edition or the old 1931 Edition of the standard is desired. The price of the new 1939 Edition is sixty cents, but the price of the old 1931 Edition will remain \$1.00 a copy for the few persons who may wish to continue using the old standard.

THE FIRST ANNUAL SYMPOSIUM FOR INDUSTRIAL NURSES

THE Illinois State Department of Public Health, through its Divisions of Industrial Hygiene and Child Hygiene and Public Health Nursing, has arranged a symposium for industrial nurses in the state, to be held October 26-28, at the University of Illinois Medical School, in Chicago.

Coöperating organizations will be: Chicago Industrial Nurses Association, Greater Chicago Safety Council, Illinois Manufacturers' Association, American Industrial Hygiene Association, American Medical Association, and University of Illinois Medical School.

UNIVERSITY OF CALIFORNIA NURSING EDUCATION INSTITUTE

AS part of the Summer Session program of the University of California, the Division of Nursing Education of the Department of Hygiene held

a 3 weeks' Institute on "Social and Nursing Problems in the Control of Syphilis and Gonorrhea." Mrs. Evangeline Morris, of Simmons College, was the prime moving force of the Institute. Dr. Malcolm Merrill, Chief of the Bureau of Venereal Diseases, California State Department of Public Health, gave a well organized practical view of the medical aspects in the control of syphilis and gonorrhea.

Enrollment included public health nurses from state, city, and county health departments, Indian Service schools, Visiting Nurse Associations, American Red Cross Nursing Services, and nurses from clinic, general duty, and private duty fields.

TRI-STATE FOOD AND HEALTH OFFICIALS CONFERENCE

THE Tri-State Food and Health Officials Conference will meet at Pittsburgh on Wednesday, October 18, during the Annual Meeting of the A.P.H.A. This Conference is composed of health and milk control officials in the States of Ohio, West Virginia, and Pennsylvania. The officers are:

President: Julius A. Pizzoferrato
Secretary-Treasurer: Thomas Henderson
First Vice-President: Dr. Reese Pedicord
Second Vice-President: Elmer Harter
Editor: Leicester Patton

Their program will include papers by Dr. W. W. McFarland, President, Pennsylvania Public Health Association; Dr. Reese Pedicord, Wheeling, W. Va.; and Fred L. Schoenberger, Secretary, Ohio Dairy Products Association, Columbus, Ohio.

FILTERABLE VIRUSES RESEARCH

Orientation in Public Health*

JOSEPH W. MOUNTIN, M.D., F.A.P.H.A.

United States Public Health Service, Washington, D. C.

WHEN preparing this paper, I was first impelled to detail some of the technics being used in the evaluation of public health procedures. But on setting them down for inspection and further delineation, it became obvious that there is no technic peculiar to studies of administrative practice. As in the case of epidemiology, the occasion may arise for drawing upon any method that has been found useful in political, social, or biological fields of inquiry. One question may be explored by statistical analyses of morbidity and mortality data; another by making physical examinations, supplemented perhaps by laboratory tests, of particular population groups; problems relating to environment may give rise to questions of an engineering character; perhaps it is the efficacy of an immunization or a therapeutic measure that is to be tested, thus a clinical approach may be needed to settle the issues involved. Since the words "public health" usually connote mass action and considerable measure of popular support, social concepts, economic resources, and costs of service

must be taken into account no less than the effectiveness of the public health procedure itself; hence the necessity often arises for having political, social, and economic sciences represented in studies of administrative practice. Perhaps the latest development in evaluation is the attempt of a few workers to utilize technics of educational measurements in the appraisal of health education.

Any one among a number of subjects might have been selected to illustrate the application of these several technics and disciplines, but at this time orientation with respect to needs and opportunities seems the most important item for study. By way of introduction, the broad question of orientation may be phrased in three separate but related parts: What is the status of the nation's health? What controllable factors are most influential in determining this status? What sort of organized effort on the part of society is needed so that individuals and communities may achieve the highest attainable level of well-being?

As measures of the nation's health, morbidity and mortality still hold commanding positions in the estimation of

* Read before the Tenth Annual Meeting of the Western Branch, American Public Health Association, Oakland, Calif., July 23-28, 1939.

public health analysts, although the slogan "positive health" which came into popular usage some 25 years ago has tended to divert attention from the more obvious expressions of human vitality. Of the two, death is the more definite phenomenon. However, it happens only once in the life of the individual whereas illness occurs many times. Illnesses of certain types are prone to terminate fatally, while others tend to be self-limited and usually end in recovery after varying periods of disability. As a matter of fact, the common cold is among the most frequent causes of illness; yet this condition is not accepted as a primary cause of death. Thus it is evident that gross mortality rates cannot be translated into illness rates, especially if one wishes to obtain an expression of disability and costs accruing therefrom.

The characteristics of mortality data and the whole procedure of certification are well understood by the group to which this paper is addressed. On the other hand, systematic collection and analysis of sickness data are rather new ventures in public health

practice; hence a few words on procedure may not be out of place.

Perfection in a morbidity intelligence service would entail a medical diagnosis for every departure from normal experienced by all members of the population, this to be reported to some central agency. Such a scheme would, of course, fall of its own weight. Furthermore, this plan is not practicable under present conditions, even in a modified form, since physicians do not see all cases of illness; neither has it been deemed expedient to make systematic reporting compulsory. Records of persons covered by prevailing sick benefit schemes afford valuable information, but these persons are highly selected as a rule on the basis of age, sex, occupation, geography, and other factors. In surveys of general illness, collecting information, by means of the family interview, from representative samples of the population, has proved to be the method of choice under present circumstances. For particular diseases, especially of the more serious types that are apt to receive medical attention, the information may

be obtained directly from physicians, hospitals, and clinics. Data on illness collected in either manner, when coupled with mortality records, furnish criteria for estimating the health status of a community that are sufficiently reliable to guide administrative action. It is rather strange that public health practice has been influenced in only a minor way by the very obvious leads that flow from such data. A few well known vital phenomena are contrasted with administrative practice to show obvious failure in the use of available information.

Very young infants, for example, have not shared equally in the reduction of mortality which has been accomplished for children of all other ages; notwithstanding, most health departments concentrate attention on older children at the expense of infants. At the other end of the scale there are accumulating large numbers of persons in the advanced age brackets who have reached the period when vital forces must be conserved; yet public health offers little to the adults who face chronic disease and declining economic efficiency.

The inappropriate distribution of public health effort becomes more apparent when mortality is analyzed by specific causes. To illustrate this point, ten of the most important causes of death in 1937¹ arrayed in the order of frequency are presented in Figure 1. Aside from heart disease which presents a rate more than twice that of its nearest competitor, other rates descend in regular order of magnitude from cancer with 112 to diabetes with 24. These conditions taken together account for more than 79 per cent of all deaths. Against only one of them—tuberculosis—do health departments take very specific action at the present time. By contrast, the whole group of acute communicable diseases on which most public health effort is directed accounts for only 3 per cent of the mortality. This differential treatment cannot be justified on the basis of proportionate reward for effort.

Another and more revealing picture is obtained by using illnesses instead of deaths to measure need for service. As mentioned previously, a person dies only once, but he may be ill many times during the course of his life. Taken in

the main, the causes of illness are quite different from the causes of mortality. If case incidence is used as the unit of measurement, the ten most important illnesses² assume positions which may be noted in Figure 2. Upper respiratory infections lead by a wide margin; accidents constitute a potent cause of disability and so do stomach troubles. For a long time diarrhea was the only one of the group to arrest attention in public health programs. In some areas efforts are now being made to combine actual care at confinement with maternity hygiene service.

An appraisal of health department programs made on the basis of measures designed to affect diseases and conditions causing the greatest amount of illness discloses deficiencies even more glaring than the one based on mortality experience. In both instances, however, most of the neglected conditions are not in the so-called acute communicable groups and because of this characteristic they have been considered beyond the purview of public health agencies up to the present time.

Even under theoretically ideal con-

ditions where all acceptable preventive measures in programs of health might be taken, a certain amount of illness requiring medical care will occur. Its severity and consequences can be reduced by appropriate care. The magnitude of the prevailing illness burden as well as its differential distribution in respect to income groups of the population³ may be noted in Figure 3. Especially the families on relief and those with annual incomes below \$2,000 are afflicted most severely, irrespective of whether incidence or duration of illness be taken as the criterion. Other data⁴ accumulated by the Public Health Service but not presented on this occasion show that the amount of care which people receive is inversely proportionate to their income. Restorative measures must not be regarded as mere patchwork. Good medical care not only saves life but it also is a means of lessening disability which follows neglected illness. Social programs, especially of the assistance type undertaken on a broad scale within the past few years, have increased awareness of the rôle which illness plays in the

causation of disability and dependency. The course of events makes it quite clear that society is preparing to organize for health in a broad way as it has already done for other purposes. Especially health administrators must contemplate how their departments may serve the public interest in this area of social action. Apparently they are poorly prepared at the present time to accept enlarged responsibilities.

In connection with the National Health Inventory the total public health structure of the 94 study counties as expressed by organized agencies was examined from several points of view. Parenthetically it may be added that most of these counties contained larger centers of population; hence they are distinctly above the average in respect to number of inhabitants and per capita wealth. Despite the favorable position of these counties from the standpoint of resources, their expenditures for the limited services commonly assigned to organized health agencies were surprisingly low. For the group of coun-

ties as a whole, the annual per capita expenditure by all agencies, both official and nonofficial, was \$.86; of this amount \$.52 was contributed by the health department, \$.11 by other official agencies, and \$.23 by voluntary agencies.⁵ Another body of data, assembled in this instance by the Division of Domestic Quarantine, U. S. Public Health Service, reveals even smaller outlays per person. The data include reports from approximately 600 counties affording through use of public funds some type of health department service, each county operating as a separate unit. Within these 600 counties, usually small in population, the median annual expenditure by health departments is but \$.42 per capita. Obviously such low expenditures are not sufficient to permit reasonable development of the limited preventive services ordinarily encompassed by the usual program of health agencies.

The extent to which special clinics have been developed has become a rather critical index for judging the

availability of preventive services. On this point the National Health Inventory disclosed some rather pertinent information for the 94 study counties⁶ which is presented in Figure 4. Opportunity for obtaining service of some type in a clinic classed as preventive is afforded in 70 per cent or more of the populous counties. In the group of counties having less than 100,000 inhabitants the presence of clinics is reported far less frequently. Here especially the variety of clinic service is restricted. Cancer and heart disease appear to be neglected more than other conditions in the scheme of clinic organization.

Another measure of opportunity for treatment outside the home lies in the existence and distribution of out-patient departments. According to a recent survey, there are about 770 organized departments attached to general and special hospitals, exclusive of federal, institutional, and proprietary hospitals.⁷ Roughly three-fourths of the existing departments are controlled by nonprofit bodies; the remainder by state and local governments. Like special preventive clinics, out-patient departments are concentrated in populous areas, especially in large cities of the northern and middle Atlantic seaboard and of the Great Lakes area. One hundred per cent of the cities with 250,000 or more inhabitants contain at least one out-patient department, while only 2 per cent of the cities with

less than 10,000 population have one or more such departments. Inasmuch as two-thirds of the aggregate hospitals owned by state and local governments and four-fifths of those operated by nonprofit bodies do not maintain organized out-patient departments, there is obviously possibility for expansion of services to ambulatory patients, especially to those of the indigent and marginal income classes whom out-patient departments are primarily designed to aid.

Since the hospital is coming to be regarded as a public health facility, it is incumbent on health administrators to learn the criteria by which to judge the adequacy and availability of hospital accommodations. On this point inquiries made by the Public Health Service show very clearly that primary consideration should be given to the scheme of financial support. Until the bed-days of care in free and part-pay categories bear a reasonable relationship to the income distribution of the population, estimates on available beds and percentage of beds occupied cannot be taken to express potential demand for hospital service. Data presented in Figure 5 substantiate this point.⁸ Hospitals that derive 50 per cent or more of their income from patients may expect their beds to be unoccupied about half the time. Obviously the mere existence of a hospital in a community is not a satisfactory criterion for judging the adequacy

or availability of a service. For a significant part of the population all charges must be remitted and for others rates must be geared to income of patients. Since a very large proportion of hospitals derive most of their income from patients, the distribution of hospitals as shown⁹ in Figure 6 should be no cause for surprise. In states where per capita income¹⁰ is lowest hospital accommodations are fewest despite the well known fact that low-income groups have the highest illness experience.

Nutritional advice may be cited as another type of service often rendered without specificity and without taking into account the realities of income. Health department workers in the nutritional field almost invariably tell their clients to drink more milk and eat more vegetables. As maxims these no doubt are more generally applicable than any others that might be substituted. The diets of families with greatly restricted incomes are generally supposed to be characterized by excess of calories and deficiency of vitamin and mineral content. A study by Wiehl and Palmer¹¹ of the summer diets of 600 selected poor families, however, leads to the conclusion that many families on relief or with very low incomes subsist on diets deficient also in energy value. In view of the very large percentage of the families who occupy the low income brackets one may ponder these points: How well

suited is standardized advice to the budget of the individual family? What specific nutritional defects do the proposed diets seek to correct? What curtailment of general food value in the family diet may result from the purchase of the proposed articles which are relatively expensive? It is hoped that the studies now in progress under the auspices of the Public Health Service and other agencies will enable the field worker to speak with greater assurance and specificity than is possible at the present time. Briefly, these studies are designed to appraise the various physical measurements together with the several chemical and biological tests applicable to human beings that are presumed to be of value in determining true metabolic deficiencies. By correlating these findings with food intake, it is hoped that more light may be thrown on the true effects of diet in relation to growth and development.

In the whole lexicon of public health perhaps no word is more often misapplied than "education." It is even alleged by some enthusiasts that all public health effort is basically education. Critics of actual practice have little difficulty in pointing out that much of the day-to-day activities of public health workers would not come within a very liberal definition of the term education. This should be no source of surprise since most of the personnel employed in health agencies

were trained to render a form of service that ordinarily has little or no educational content; yet these workers assume the rôle of educators upon finding employment in a health organization. Even if one may concede that the material used by health agencies is scientifically correct, the process of education has only begun when the person is informed. The recipient of this information must be activated to the point where he will follow the correct course irrespective of the inconvenience that may be entailed. It would therefore be well for the public health profession to apply to their educational efforts the criteria commonly used in evaluating the procedures designed to influence human conduct.

Those among the present generation who were inducted into public health work when Sedgwick reigned supreme regret the rather low position that is now accorded the routine sanitation activities of health departments. In large measure this fall from high esteem results from the fact that later day workers in this field pay less attention to biological principles on which sanitation should be based than did their forebears. Too much of current activity represents little more than rituals that have been solidified in codes and made impressive by gadgets. Up to now the more significant contributions of sanitation have been in the control of intestinal infections and infestations. Air-borne diseases, and some of virus origin, may yet be influenced by environmental measures. The effect of environment on physiological processes is appreciated but very poorly understood.

No doubt many of the administrative problems involving procedures on which questions may be raised, as well as the needs that remain unsatisfied, would have been resolved had the public health field been able to attract and retain a sufficient complement of per-

sonnel possessing the necessary qualifications. By qualifications is meant something more than mere scholastic attainments as expressed in credits and degrees. Occupying positions as health officers and bureau chiefs, we should like to see persons who combine sound judgment, professional competence, and strong emotional appeal. Most of the subordinate positions call for independent work; hence central direction and planning, no matter how well organized, can never be substituted for individual ability in the ranks. The building and maintenance of a suitable staff is a never-ending job. Induction, development, and replacement must go on simultaneously. That relatively few governments carry out even the first step in a systematic manner is illustrated in Figure 7.¹²

Only one-third of the states and under two-thirds of the cities with populations of 10,000 or over on which data were assembled by the Public Health Service employ any persons under a merit system. Personnel is selected by interview in roughly one-third of the jurisdictions; it is selected by examination in one-third of the states and in over one-half of the cities. Promotion is based on administrative discretion entirely or some scheme involving it as one of several factors in three-fifths of the states and two-fifths of the cities. Needless to say, such policies scarcely conduce to long tenure or security.

The situation among counties is not so clearly defined or so easily described as that for states and for cities. Inasmuch as state departments exert considerable financial and policy control over county departments, there results in effect a continuing effort toward a degree of conformity, not to say uniformity, of practice, that operates to stabilize the local departments. Literally, state departments require more systematic personnel procedure of

counties than they themselves show. While civil service and merit systems as such on a county basis are almost nonexistent, the professional character of the employers, as evidenced by tenure and training, is well above the average for all departments encompassed by the study. Aside from the influence on personnel policy that is exerted indirectly by the state health agency, through one device or another, counties and the smaller cities especially seem remiss in making necessary legal provisions for selection and advancement on a merit basis. As to retirement allowances, state and local governments have always been notoriously negligent.

By studying the employment record of health officers, one finds that a median of 3.4 represents years of employment for all full-time health officers listed in directories published by the Public Health Service during the period 1912-1935.¹³ With such frequent turn-over, the problem of training represents a rather discouraging task. It is a source of gratification,

however, to note that professionalization as expressed by length of full-time employment has gone on to a greater extent among staff employees than among chief administrators. As a result perhaps of the fact that large cities were first to develop full-time staffs of appreciable size, personnel in these political subdivisions show longer periods of service than obtain in either state or county organizations.

Despite the lack of legal provisions for security which characterizes public health positions, some encouragement may be found in the fact that slightly more than half of the aggregate full-time medical, nursing, and sanitation personnel in official agencies have attempted to equip themselves for their jobs by obtaining some type of instruction in their chosen work.¹⁴ It is true, however, that only one-third of those with training have attended what may be described as formal organized courses in public health work; the remainder of this group have received only field training, usually in the form of special courses of short duration.

These points are illustrated in Figure 8.

From the standpoint of formal public health education, physicians take precedence, as 30 per cent of them report such training. Somewhat fewer have attended special or field courses; nearly one-half are without scheduled training. In contrast, only 20 per cent of the nurses have received formal instruction, but a much larger percentage have participated in special courses, so that only slightly more than one-third are without particular training. Sanitarians show least specialized preparation in that 71 per cent have failed to take either formal or special courses; 5 per cent possess formal training; and the rest have some measure of less systematic preparation. In the instance of each class of personnel—medical, nursing, and sanitation—a higher percentage of executives and supervisors than of staff members have received both formal and field instruction.

If the three classes as a whole are broken down by types of jurisdiction, county and district health department employees show substantially more specialized training than either city or

state employees. Almost two-thirds of all county employees are shown to have more than basic training, but only two-fifths of city and about one-half of state employees are so equipped. The outstanding groups, each of which shows over 70 per cent of its members with either formal or field public health training, are county health officers (71.7 per cent) and county nurses (71.7 per cent). State nurses, as a group, follow with 65 per cent thus trained.

The fact that certain classes of personnel have received either formal or field training gains significance when associated with the amount of time devoted to the various courses. Measurement of the duration of special courses is not attempted in this analysis since it is impossible to determine the intensity of such courses. In Figure 9 is given the distribution of formally trained personnel according to the periods spent in study. Obviously 1 year is the interval most commonly spent in special preparation since 54 per cent of all trained employees have devoted this period to additional study.

In one respect nurses are better equipped for their work than are either physicians or sanitarians, for 16 per cent have received 2 or more years of formal public health training as opposed to 10 per cent of the physicians and 8 per cent of the sanitarians. On the other hand, 30 per cent of the nurses have received less than 1 year of formal instruction, a figure slightly above that for medical personnel. With the possible exception of the medical class, employees serving in executive and supervisory positions have secured more prolonged training than have staff employees.

This paper, by design, has been somewhat broad and discursive in its coverage. In some respects it may be considered a departure from the main theme of this symposium—"Evaluation of Public Health Procedure." The broad subject "Orientation" was chosen because public health is dominated by the specialized groups within its ranks, who are concerned primarily with promoting their interests and perfecting their technics. Within limits this influence is desirable but there results a tendency to miss the forest

because of the trees. Especially in these days of changing social concepts and rapid development among all the sciences, it seems that we should pause for a moment now and then and pose for ourselves this rather colloquial question: Where are we and where do we go from here? That the people want health and are expressing a willingness to pay for it is evident. If the movement is to go forward under the banner of those agencies which bear the title "Department of Health," administrators must face some rather fundamental issues. These may be stated very briefly: How well suited is the orthodox program of health departments to the needs of the people? What rôle is the department willing to occupy in areas beyond its traditional interest? How well equipped are public health groups to carry such additional functions as they may be called upon to discharge? This paper represents an attempt to set up a few bench-marks for purposes of orientation and to suggest criteria for determining progress in selected fields, some of which are now occupied, others of which need to be explored.

Cross Purposes

AN unidentified newspaper clipping, presumably from a Philadelphia newspaper, carries the interesting information that a Philadelphia hospital and an antivivisection organization each received \$5,000 under the will of a woman who also bequeathed \$1,000 to a dog and cat hospital. This is an ironical comment on what was undoubtedly a totally unintended result of these bequests, namely that one of them will be used to defeat the purposes of the other two. The bequest to the hospital and to the dog and cat hospital will be used for the treatment of human beings and animals suffering from disease. This treatment will be preceded by diagnosis based on knowledge obtained from animal experimen-

tion. It will include methods of treatment, both medical and surgical, based on animal experimentation. Even the well chosen diets which will adorn the trays of the human patients and the rations which will restore ailing animals to their owners in prime condition are computed on the basis of information depending in large part on animal experimentation. The bequest to the antivivisection society will be used to cripple, harass, and defeat the efforts of scientists to use animals in the investigation of the remaining problems and mysteries in the field of health and disease. Thus unconsciously this testator has made one bequest which will neutralize and set at naught the effects of another.—*J.A.M.A.*, Aug. 19, 1939, p. 684.

The Problem of Maternity— A Survey and Forecast*

LOUIS I. DUBLIN, PH.D., F.A.P.H.A.

Third Vice-President and Statistician

Metropolitan Life Insurance Company, New York, N. Y.

THE problem of safeguarding maternity is an old one but the program which has been developed specifically to control the situation is, in this country at least, of recent origin. Quite a number of us, I am sure, participated in the early steps which were taken about 25 years ago. Many of us have seen the several stages in the development of a program which is now nation-wide and which has every earmark of being successful. While the accomplishments to date have not been startling, as in the campaign against tuberculosis, typhoid fever, or diphtheria, they have, nevertheless, been noteworthy and encouraging. We can now safely say that we have learned how to overcome what only recently looked like a serious deficiency in our medical practice. It is necessary only to make available more generally services which have proved effective.

For a long time the high maternal death rate of American women was nothing short of a disgrace. Everyone seemed to be conscious of the situation and deplored it. In the effort to enlist public support for the movement to reduce the hazards of childbearing, it was a common practice to show the maternal mortality rate of a long list of countries with the United States always appearing at the bottom of the

list or close to it. Only Chile and a few other countries of notoriously low medical standards showed conditions as bad or worse. The actual figure recorded was 7 maternal deaths per 1,000 live births in the states for which reliable data were then available. Special studies of underprivileged groups showed much higher figures—10 per 1,000 and even more in congested urban areas. In contrast, there were the Netherlands and the Scandinavian countries with maternal mortality rates under 3 per 1,000 live births. How did these countries with no better medical facilities, and with certainly no higher standards of life than our own, provide protection and services for their women which consistently produced maternal death rates less than one-half ours? That was the challenge.

Here certainly was an opportunity for the launching of a public health campaign which would win wide support. The Children's Bureau, established in 1912, took leadership in the movement, but with limited funds and no administrative authority accomplished relatively little in its early years beyond the publication of several studies and the distribution of minimum standards. It was not until the passage of the Sheppard-Towner Act in November, 1921, that an effective na-

* Presented at the American Congress on Obstetrics and Gynecology, Cleveland, Ohio, September 13, 1939.

tional movement was inaugurated. This legislation provided several million dollars of federal funds between 1922 and 1929 to those states willing to make necessary supplementary appropriations for maternity and infant welfare activities. The Act called for the establishment in each state of a responsible administrative agency, usually a child hygiene bureau. In this way standards of prenatal care formulated by the Children's Bureau were incorporated in the practice in the various states.

Even before the passage of the Act, many states had created maternity and child hygiene bureaus. At the beginning of 1921, 33 such state agencies were already in existence. By 1929 when the Act expired, maternity and child hygiene bureaus had been created in virtually every state in the Union. According to state reports, in the last 4 years alone more than 4,000,000 infants and preschool children, and about 700,000 expectant mothers were reached by some form of maternity and infancy work. It was thus primarily through federal activity that nation-wide interest was aroused in the welfare of mothers and babies, that large numbers of women received instruction in maternal and child hygiene, that public health nurses were appointed in large numbers to render services in the homes of pregnant women, and that steps were taken to reduce the menace of the inefficient and unclean midwife through registration, supervision, and instruction.

But from the very beginning there was the pressing need for a decisive demonstration of how best to organize a local effort to control the unnecessary maternal and infant tragedies. This object lesson in life conservation was the contribution of the Maternity Center Association of New York. This Association, organized in 1918 by a particularly able and determined group of women, soon became a militant and

effective center of service and propaganda. Frances Perkins was the first executive secretary and Mabel Choate, as president, provided the leadership. From its inception this association included a number of New York obstetricians, leaders in their field, who gave authority and direction to the plans. This is an appropriate time and place to record the unremitting labors of the late Dr. Ralph W. Lobenstine, the first chairman of the Medical Board of the Maternity Center Association, who watched and guided every step in the development of a sound program. This New York association and similar ones which have been organized since in other parts of the country are truly Dr. Lobenstine's monument.

The function of these Maternity Center Associations was first to develop a sound public opinion which would demand correction of the existing evils; second, to organize a local service which would demonstrate that safe maternity care could be made available to large numbers of women at a reasonable cost, and third, that such services could readily be extended to cover sizable areas of the population. The nucleus around which the service was developed was a local public health nursing group operating under close medical supervision in the homes of their clients and in clinics. While a few of the nursing leaders had acquired specialized training, the majority of the rank and file perfected their routine as they worked; for the art of prenatal nursing was still very young. They visited mothers at home and helped prepare them mentally and physically for labor and delivery. The nurses took blood pressure, temperature, and pulse readings, made urinalyses, watched for all the danger signs, listened to the fetal heart, checked on dental care, diet, rest, and the other essentials to healthful living. At the same time, the nurses concerned themselves with such conditions as poor

housing and family maladjustments, which interfered with the mother's peace of mind.

I was associated with this movement in New York City from the beginning, and I prepared with the assistance of the then director, Anne A. Stevens, the first study of the results which were achieved by the Maternity Center Association. The association provided, for the most part, only prenatal nursing care for its clients. The results were distinctly useful and encouraging. The intensive follow-up of the women through urinalysis and medical examination and subsequent advice reduced the number of maternal deaths from albuminuria and convulsions to one-third the usual number. Prenatal care was obviously effective in reducing the toxemias of pregnancy. This effort likewise reduced the number of infant deaths from prematurity by two-thirds and the number of stillbirths by about one-half.

The results were obviously good and were enthusiastically received as a great achievement. But on further analysis distinct limitations were found. Our study showed that deaths of mothers from causes other than toxemia had not been favorably affected. Deaths from the accidents of pregnancy and of labor, and from puerperal hemorrhage remained about the same as in the general population. Apart from prematurity, the hazards that affected babies during the first month of life were pretty much the same as in the population at large. One of the shocking results of our study of this experience was the very high mortality of mothers cared for by the association during pregnancy but delivered in some of the New York City hospitals, the rate being 11 per 1,000, or about twice that prevailing in the general population. Of the hospitalized cases, half of the deaths were due to septicemia. This study reflected the

inadequacy of the care given to women during and after labor in some hospitals in the city and proved, if further proof were necessary, that the program of the Maternity Center Association had been too narrowly conceived. Supervision of pregnancy was obviously of value, but in itself was not sufficient to safeguard the life of the mother and baby. Of equal, or even greater importance, was the preparation and supervision of the confinement and the postpartum care of the mother and child.

In 1922 the Maternity Center Association offered to the mothers under its care in the demonstration area medical and nursing supervision, instruction during pregnancy, help in arranging for delivery, nursing assistance at time of delivery, nursing supervision and instruction during the postpartum period, postpartum medical examination, and help in arranging medical supervision for the baby and further care for the mother when necessary. Each mother was urged to register as early as possible in pregnancy with the doctor or hospital physician who would deliver her. This was clearly a well rounded program intended to cover the entire maternity cycle and to supplement the existing medical and hospital facilities for delivery care. Fortunately a sizable group of women in the Demonstration Area took advantage of this service.

A new study of the results for the years 1922 to 1929¹ which I made in 1930 in collaboration with Hazel Corbin, Director of the Maternity Center Association, showed clearly that the care provided by the association reduced the mortality of mothers to about one-third of that among women in the control group. Deaths from eclampsia were entirely eliminated, those from sepsis greatly reduced, and the remaining few fatalities were, in the judgment of the Medical Board, unpreventable in

character. Stillbirths were 42 per cent lower, and infant deaths in the first month of life were reduced 32 per cent. I studied the records of the Frontier Nursing Service inaugurated by Mary Breckenridge in the difficult areas of the hills of Kentucky. The results were even more striking in terms of maternal lives saved through good nursing and skilled obstetric care as rendered by nurse midwives. On the basis of these demonstrations we were entirely justified in our claims that the lives of 10,000 women could be saved annually; that about 40,000 stillbirths could be prevented, and that some 30,000 infants who died under 1 month of age could be kept alive provided similar services and results were general for the women of the country.

While these maternity demonstrations were being developed in New York and in other large centers of the country, there was also an increasing awareness on the part of the medical profession that the woman in pregnancy and at confinement needed a larger measure of supervision and expert care than she was generally receiving. The profession now realized that the training of the average practitioner, and certainly that of the average midwife who were caring for the great majority of the confinements in this country was woefully inadequate. Special investigations were launched to determine in detail the circumstances under which women died in maternity, and to place more definite responsibility for these fatalities. The first comprehensive investigation was that planned and supervised by the members of the Obstetric Advisory Committee of the Children's Bureau. It covered an area of 15 states and the period was 1927 and 1928.² The facts revealed by this study led inescapably to the conclusion that maternal deaths were due in large part to controllable causes. The recommendations drafted by the Advisory Com-

mittee on Obstetrics advocated that physicians assume leadership in the program for control and that the general public be educated regarding the need for and meaning of adequate maternal care.

Perhaps more dramatic and significant in its nation-wide influence on the medical profession was a study begun in 1930 by the New York Academy of Medicine.³ This investigation covered a 3 year period and was extremely well organized by the leading obstetricians and gynecologists of New York to determine responsibility for each maternal death reported during the period. Every fatality due to a puerperal condition was investigated by personal interview with those connected with the case. The hospital records were studied at first hand. The evidence was carefully analyzed by expert committees, and all cases were assigned specifically to either preventable or non-preventable causes as the evidence indicated.

The investigation showed that two-thirds of all the deaths studied could have been prevented if the care of the woman had been proper in all respects, a finding which tallied remarkably well with that obtained by the Maternity Center Association and other groups in their preventive demonstrations. The study, as you all know, revealed a number of shocking conditions surrounding the care of childbearing women. Prenatal care was too often inadequate and improper. Operative interference during labor was resorted to in too many instances. Often the operation chosen was the wrong one, undertaken inopportunistically, and demanded greater training and skill than the attendant could command. Such was the objective judgment of the most skilled men of the profession on the evidence before them.

Sixty per cent of all the preventable deaths were traceable to some incapacity in the attendant—lack of skill,

lack of judgment, or careless inattention to the demands of the case. Some of the fatalities grew out of the fact that internes had too wide a field of independent activity. The investigation in addition showed that more than one-third of all preventable deaths were due to some failure on the part of the patient herself to take advantage of the facilities which are at hand for safeguarding her in the period of gestation and lying-in.

Hospital standards were inadequate in many instances. Proper facilities for labor and delivery were lacking, isolation was not always carried out promptly. In some proprietary hospitals, the operating room was also used as a delivery room. In some hospitals the resident staff was given too great responsibility. Exacting and difficult obstetrical operations were being performed by the junior members of attending staffs without consultation with their chiefs.

It was clear from this and from other investigations that both medical personnel and facilities were generally inadequate to insure safe maternity. For the national welfare it was necessary that better obstetrical training be given in the medical schools and in hospitals to qualify the rank and file of general practitioners; that specialists be designated only after adequate graduate study; that the nursing personnel and midwives receive more specialized training; that obstetric hospitals be architecturally segregated from the other services, and that in such hospitals operative procedure be more adequately supervised to assure necessary skill in those taking responsibility. Emphasis was placed on the need of full records as the basis of frequent and regular conference by the staff to determine the causes for failure.

But it takes time to set up facilities for the adequate care and supervision of women during pregnancy and in

their confinement in a country as large as ours. In spite of all the undoubted efforts of the medical profession and of the many groups of lay workers, public health nursing organizations and others, there was a long lag before the death rate from puerperal causes responded favorably. Even as late as 1930 the maternal mortality rate in this country was 6.7 per 1,000 live births, or only slightly less than the maximum of the earlier years. But since that year the mortality from puerperal causes has declined, at first slowly and later more rapidly and without interruption. By 1937 maternal deaths had already been reduced to 4.9 per 1,000 live births, a figure 27 per cent below that for 1930. Moreover, there is every reason to believe that when the rate for 1938 becomes available for the country as a whole, a further drop will be evident, almost to the point of 4 per 1,000 live births. Thus far in 1939 the same tendency is in evidence. In New York City and New York State, the figures for 1938 were 3.7 and 3.5 respectively. I am inclined to believe that a decline in the rate of about 10 per cent per annum is now prevailing generally over the country.

On further analysis we find that the decline in the maternal mortality rate reflects an increasing control over each of the major hazards of childbirth. The mortality for puerperal albuminuria and convulsions has dropped no less than 39.5 per cent between 1930 and 1937. For puerperal septicemia the rate per 1,000 live births has declined from 1.50 in 1930 to 0.95 in 1937, or 36.7 per cent. In the corresponding period, deaths from puerperal hemorrhage have been reduced by 14.5 per cent. Even deaths from abortion with septic conditions, which increased between 1930 and 1935, registered a substantially lower figure in 1937 than in 1930. (See Table 1.)

It appears then, from this brief

TABLE 1

NUMBER OF DEATHS PER 1,000 LIVE BIRTHS FROM PUERPERAL CAUSES, UNITED STATES
1930-1937

<i>Cause of Death</i>	1937	1936	1935	1934	1933	1932	1931	1930

survey, that the movement for maternal welfare has finally come into its own. As we have already pointed out, many influences have been at work. This is a good occasion to pay our respects to the public health nursing organizations of the country which have played a major rôle in the development of the campaign to control maternal mortality. Public health nurses have been the instruments for carrying the message into the home, whether the work done was under the auspices of state and local health departments or by local maternity associations. In most areas it was the local visiting nurse association which took upon itself the responsibility for educating mothers in the community regarding approved practices in prenatal care and confinement. We cannot exaggerate the importance of this nation-wide service carried on by 20,000 public health nurses in every state of the Union, and extending down to the smallest geographical subdivision.

A good example of an agency operating through visiting nurses is the

Metropolitan Life Insurance Company, which throughout this period has developed and made available a service to its policy holders to control unnecessary maternal deaths. At the very beginning of its welfare program in 1909, the company emphasized this phase of bedside nursing, and as the service grew to include a larger number of its policy holders, more and more emphasis was put on the care of mothers in pregnancy and postpartum. In some areas, such as Canada, more than half of all the nursing visits were concentrated on the care of the puerperal state. It is, therefore, interesting to observe what has occurred in this group of people, for the most part the wives of wage earners living in congested areas of cities. In 1911, the first year for which data are available, the puerperal mortality rate among the millions of industrial policy holders was 19.8 per 100,000 lives insured. In 1938, the figure had been reduced to 6.2, or a reduction of almost 70 per cent. During this period the birth rate, of course, likewise declined and it is,

therefore, necessary to convert these figures into corresponding maternal mortality rates per 1,000 live births. When this is done, we find that there were 7 maternal deaths per 1,000 in 1911, as compared with 3.5 in 1938. In general the decline among the insured has been very much like that in the general population, perhaps a little more accentuated because of the more intensive efforts concentrated on these women. It must be remembered that these represent a group whose mortality might be expected to be somewhat higher than that of the general population. It is very encouraging, furthermore, to point out that in the last few years the decline has been at its maximum, of the order of 10 per cent per annum. There is no indication as yet of any lessening in the velocity of the improvement.

Another major influence has been the activity of the medical profession in

raising the standards of obstetrical practice on a large scale. The results of the earlier surveys were evidently heeded, and we find in many large and even small centers an improvement of local organization for supervising hospital service, as well as individual practitioners. Fortunately the trend the country over has been toward more and more confinements under medical auspices and more particularly in hospitals. Dr. S. C. Runnels, Secretary of the Hospital Obstetrical Society of Ohio, summarizing this phase of the problem recently⁴ pointed out that the number of births in hospitals reporting to the American Medical Association has increased 46.5 per cent between 1934 and 1938, and, more important, that the increase has been entirely in the larger hospitals. Cases in hospitals handling more than 100 births a month increased 60 per cent; in those handling from 50 to 100 births, cases more than doubled.

GEOGRAPHIC VARIATION IN MATERNAL MORTALITY UNITED STATES, 1935-1937

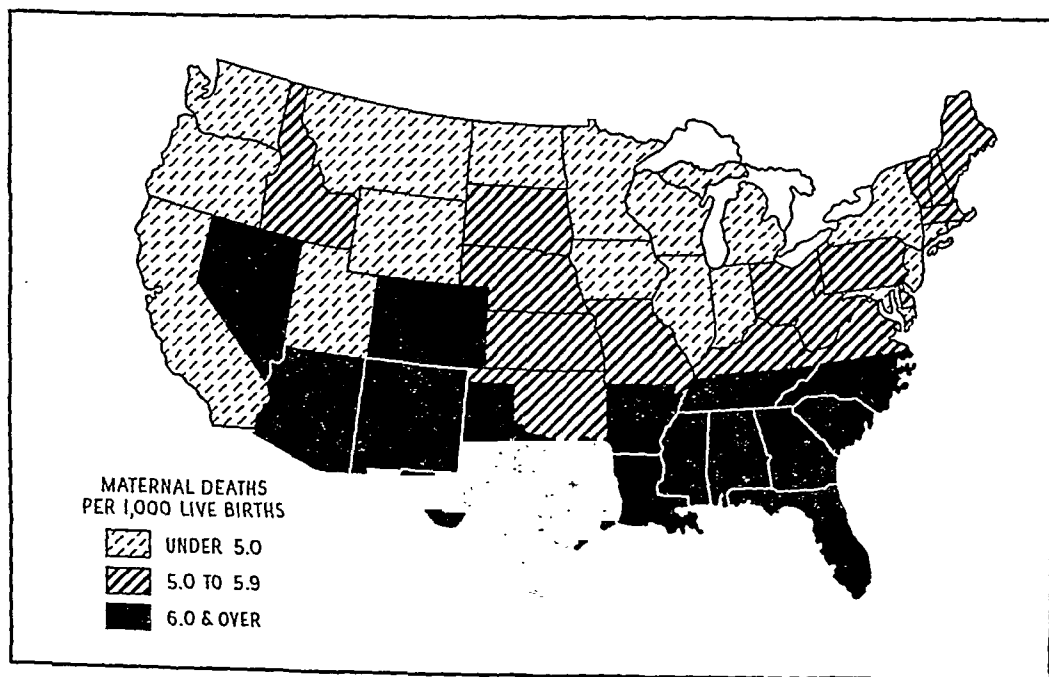

TABLE 2 — Maternal Deaths per 1,000 Live Births, Per cent of Live Births in Hospitals, and Per cent of Live Births Attended by Physician in White and Colored Population, by States, 1937.

* Attended by Physician

† Based on less than 25 live births

On the other hand, confinements in hospitals caring for less than 13 cases a month showed a decrease of 14.4 per cent in this period.

That this factor of increasing care in hospitals is an important one in reducing maternal mortality is indicated by the definite and intimate relationship existing between the extent of hospitalization and maternal mortality. Generally speaking the states having the highest percentage of confinements in hospitals are those with the lowest maternal mortality. I have computed for white women the coefficient of correlation between maternal deaths and the per cent of births in hospitals for the 48 states. The figure is $-.39 \pm .12$ which indicates that the result is statistically significant. The correlation would be even higher were it not for the fact that large numbers of women are rushed to hospitals in serious condition with the hope of being saved. Thus hospitals are charged with deaths of mothers for which they have little or no responsibility.

Great as the improvement of recent years has been, there is still much to be done. The number of maternal deaths in the United States is even now about 10,000 per annum. Our country is still far behind many others in safeguarding maternity. Many women still come under care too late in pregnancy. Puerperal conditions continue to be among the leading causes of death for women in the childbearing ages. Between the ages 20 and 34, puerperal deaths are outranked only by tuberculosis. But the stage is set, as we have seen, for substantial and rapid improvement. It will be helpful in this connection to know where the problem is concentrated, among which groups of people, and in what areas of the country. That should help us to know where and how to concentrate our effort—to use the rifle rather than the shotgun, as has been our custom in the

past to bring about effective results.

States vary enormously in the safety which they afford childbearing women. The maternal mortality rate in 1937 ranged from 2.5 per 1,000 live births in Connecticut to 9.2 in Nevada. Fifteen states recorded rates of 4 or less per 1,000 live births; 10 states, on the other hand, showed puerperal deaths in excess of 6 per 1,000 live births. The highest death rates are registered in the southern parts of the United States and more particularly in the southeast. In most of this large area of the country, where the birth rate is highest, the maternal death rate is still as high as the figure we deplored 25 years ago. This highly unfavorable experience is due, in large measure, to the high proportion of colored women giving birth in these states; for it is among the colored especially that the problem of maternity is still a serious one. For the United States as a whole in 1937, the puerperal mortality rate among the colored was 8.6 per 1,000 live births, or more than twice that for the white. Four states—Arkansas, Florida, Tennessee, and Texas—actually recorded maternal mortality rates among colored women of 10 or more per 1,000 live births. (See Table 2.)

I must not, however, give the false impression that the problem is now limited to a small area of the country or to one particular race. The fact is that needlessly high maternal mortality still exists very widely throughout the country and strikes various groups and races of people. The common factor, I believe, is low economic status, and particularly is this true in areas where good medical and hospital facilities are not available. This is not the time to review the statistical evidence upon which this conclusion is based. It is sufficient to say that the literature is fully convincing on that score. I do not mean to imply that we know all that we should with regard to the

effects of economic status of the family, the occupation of the mother, the type of care at confinement, and a number of other obviously important factors. Our records must be improved to enable us to make an analysis of these items on a national scale. But, generally speaking, we know that our future progress will depend upon the degree to which the newer type of medical, nursing, and hospital facilities is made available to the neglected areas and groups of people.

Personally I feel very confident that the current developments in the public health movement will carry us far and rapidly toward the goal of safeguarding maternity and infancy in our nation. Under the leadership of the federal and state health services and the various national voluntary health organizations, I can see a public more and more enlightened as to their needs and encouraged to demand the creation of the required facilities. The type of organizations and the character of the technics have been thoroughly developed in a large number of centers. These must be made more general, so that every section of the country is covered, the southeast as well as the northeast, in the service of the colored people as well as for those in the more privileged groups. The entry of the federal government into the picture is full of encouragement, for in this way the economic inequalities of the several parts of the country can and will be corrected. But even with facilities available, there will still be the problem of educating expectant mothers to take advantage of the care that is available. Intensive effort must still be made to urge mothers to seek prenatal care early in pregnancy, and to learn how to make the necessary arrangements and adjustments which will carry them through confinement safely. That will always prove to be the last and hardest job to do.

I am confident, however, that under the leadership of the medical, nursing, and public health professions, this will be accomplished. The fact is that it must be done. The time has come when, as a people, we must realize the significance of maternity in national terms. Our country has been in the red on the score of true natural increase of population for nearly 10 years. Maternity must be safeguarded. The fears must be lifted from the lives of women that they may accept the obligation of maternity gladly. We have never realized the full significance of the effect of the current dangers on the mental health of our people. We can, therefore, look to those guiding our educational and mental hygiene movements as our natural allies. There is, furthermore, the good will for the asking of every welfare and spiritual agency in the community, including the churches, women's groups, and others, provided we make it possible for them to help us. Therefore, I say the outlook is extremely promising. If the movement has been slow in developing we can now be perfectly sure that the work can be done efficiently and economically. The time has arrived when we can, with pride, look everywhere to developments which will be commensurate with the intelligence and the rich medical facilities of our people and our need for safeguarding every human life.

Industrial Hygiene— Retrospect and Prospect*

J. J. BLOOMFIELD, F.A.P.H.A.

Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

THIS year marks a quarter century in the history of our Section. Our silver anniversary finds us larger in number, proud of the things accomplished, and enthusiastic about the work yet to be done. We can be gratified by the fact that the accomplishments which have been made in the field of industrial hygiene are the collective contributions of personnel from all professions—physicians, engineers, chemists, statisticians, nurses, and others. We have learned that industrial hygiene is not a monopoly of any one profession, but that all of them working closely together have made progress in the attainment of our common objective.

Of late, we have come to realize that no matter where our work finds us, be it in industrial plant, insurance company, university, or official public health organization, we are primarily interested in promoting health among workers. We have also reached the conclusion that no one agency can ever hope to cope with all the problems in industrial hygiene. Although the responsibility for the health of the industrial worker rests primarily on the shoulders of state and local administrations, it is realized that a plan has to be formulated, which will include all

of the agencies interested in industrial hygiene, so that all phases of the subject will receive attention. In other words, all agencies in a locality, official and unofficial, should be marshalled in the campaign to control and prevent disease among workers.

I think we should all ask ourselves the fundamental question, "As industrial hygienists, what is our responsibility in this field of public health?" Years ago we considered our responsibility the control and prevention of accidents in industry. In the last few years our attention has been focussed on the prevention of occupational diseases. Last year,¹ in discussing the development of industrial hygiene in the United States, I called your attention to the important problem of sickness among the gainfully employed. I believe we must consolidate all the gains we have made in the control of accidents and occupational diseases and never relinquish our vigilance concerning these phases of industrial hygiene. However, we should not be satisfied with the achievements of the past, but should continue to expand our activities; the reduction of lost time due to all types of disability among workers is one such worth while activity.

I believe it most fitting at this, our first quarter century of existence, to look back on the things past, to evaluate our accomplishments, to contem-

* Chairman's address presented before the Industrial Hygiene Section of the American Public Health Association at the Sixth-eighth Annual Meeting in Pittsburgh, Pa., October 17, 1939.

plate what still remains to be done, and to see if we cannot chart a future course based on present indications.

RETROSPECT

LEGISLATION

A year ago I pointed out that there were 21 states providing compensation to workers suffering from occupational diseases. During the past year, 2 states, namely, Maryland and Idaho, enacted legislation providing compensation to workers for occupational diseases. Both of these states enacted so-called "schedule" compensation laws. Arkansas, one of the two states which until now has not had any type of compensation, passed legislation this year providing benefits for injuries due to accidents and occupational diseases. Unfortunately, the law was challenged, so that 2 years must elapse before the people of the state will have an opportunity to decide whether the law should go into effect. This year Ohio amended its schedule compensation law into what is practically a "blanket" coverage occupational disease law, by the simple addition to its schedule of one more item called "any other occupational disease."

We have all known from experience that the cost of prevention of injuries caused by accidents, or by occupational diseases, is but a small fraction of the total compensation cost. Today, it is sound economics to prevent rather than to compensate for occupational diseases. Hence, it is gratifying to note that legislatures are recognizing the need for enacting laws concerning prevention. This year the legislatures of Idaho, Maryland, Utah, Montana, and Minnesota enacted laws requiring the reporting of occupational diseases to the state health department and authorizing the state health department to conduct industrial hygiene activities. The preventive features of the new law

in Maryland are of particular interest, since there is a provision that the State and Baltimore Health Departments, concurrently, receive reports of occupational diseases, study occupational diseases and ways and means for their control and prevention, and make the necessary rules and regulations for such control and prevention. Such rules and regulations shall have the force and effect of law. These health departments also have the duties to investigate industrial health hazards causing, or suspected of, causing occupational diseases, to make recommendations for the control of such conditions, and to enforce regulations regarding occupational diseases. The law also entitles the health department to recommend to the legislature for enactment such measures, including additions to the list of occupational diseases, as their studies and experience may demonstrate to be advisable.

ADMINISTRATION

Unofficial agencies—Not long ago, Dr. McConnell,² in a paper discussing the activities of independent agencies in the field of industrial health, classified them into general groups, such as private foundations and national associations, universities, trade associations, insurance carriers, industrial and mercantile establishments, and labor groups. I will not take the time to review the work of all these independent agencies, since Dr. McConnell has done it so excellently in his discussion. However, I should like to list some of these agencies and to note the contributions they have made in the field of industrial health.

The research work carried on by the Air Hygiene Foundation of America, Incorporated, whose headquarters is here in Pittsburgh, has gone a long way toward the advancement of industrial health through the study of occupational diseases. The Foundation has con-

tributed considerable material to the literature of industrial hygiene by publishing reviews and bibliographies of occupational diseases.

Such agencies as the American College of Surgeons, the National Industrial Conference Board, the National Safety Council, the American Standards Association, the American Society of Heating and Ventilating Engineers, the Illuminating Engineering Society, the National Tuberculosis Association, the Saranac Laboratory for the Study of Tuberculosis, and numerous others are taking a deep interest in the subject and have contributed considerable data. The contributions of the American Medical Association have been augmented and coördinated through the formation of the Council on Industrial Health.

Industry has for some time been very active in the field of industrial health, and of late has contributed much to the preventive phases of this problem. The National Association of Manufacturers recently appointed a committee on healthful working conditions. This committee is especially interested in bringing industrial hygiene programs to the small plants, which are in no position to carry on such a program of their own accord. Among the trade associations, the work of the American Foundrymen's Association is noteworthy. This particular agency has been active in the development of good practice codes⁸ in the foundry industry, and in the collection of data for the purpose of developing information whereby the objectives of the various codes may be achieved.

Nearly all of the insurance companies, especially those who act as compensation carriers, maintain industrial hygiene laboratories for the study of existing industrial health hazards and the means for controlling these hazards. During the last year or two, many labor organizations have increased their efforts

to promote health among their members.

I have only presented a partial list of the various unofficial agencies active in the field of industrial hygiene, but I think the lesson to be gained from all this is that the official agency in any community responsible for the protection of the health of workers cannot overlook the work of these unofficial organizations, and should develop a plan for coördinating all the activities in the community.

Official agencies—A year ago I observed that in the short period elapsing since the passage of the Social Security Act the development of industrial hygiene has been rapid. At that time, a summary of the industrial hygiene units in the various states was presented, along with the number and kind of personnel engaged in this work, and the annual budget for each unit. During the past year, several new states have undertaken industrial hygiene work, among them being Idaho, Colorado, and Utah. In addition, several large cities, such as Los Angeles, are undertaking this type of activity. I have already listed the several states whose legislatures passed laws providing for the establishment of industrial hygiene within the state health department. It is gratifying to note that some of the states actually appropriated funds for the conduct of this work, so that there is less dependence upon federal government subsidy. It should also be noted that many of the industrial hygiene units have strengthened their organizations by acquiring trained personnel and by expanding their activities.

One of the points stressed in my address a year ago was the necessity for a closer coöperation between the industrial hygiene personnel in the central organization and the various local public health units, such as city, county, or district health departments. During the past year we have seen such a

coöperative plan develop and work successfully in several of our states. It has also been possible during the past year to note progress in the plan for integration of industrial hygiene with the other health services in a community, so that public health is brought directly to all the gainfully employed in the state.

In order to illustrate how such an integrated effort can work successfully, I should like to present the activities now going on in Utah. At present, the Division of Industrial Hygiene of the National Institute of Health is conducting a coöperative study with the Utah State Board of Health, concerning the nature and extent of occupational diseases in Utah. The information so obtained will be used as a guide in the enactment of legislation for the compensation of injuries to health resulting from exposure to industrial health hazards and in the support of a permanent program designed to control such hazards. Without going into the details of the study itself, I should like to list the various health services in the State Department of Health coöperating in the investigation. For example, the District Health Officers of the areas in which the studies are being made are taking an active part in assisting the Service physicians in the physical examinations of the various workers. All serological examinations are being made by the State Board of Health laboratories. The Dental Division of the State Board of Health furnishes the services of a dentist for oral hygiene studies. The Division of Epidemiology is collecting information on the prevalence of various diseases in the communities in which the establishments being studied are located. With reference to the environmental investigation, the State Division of Engineering is assisting in the study of the working environment and is also making sanitary surveys in the communities in

which the workers live. Thus, we will have information not only on the exposures of the employees while at work, but also the conditions under which they live. It is evident that by such an integrated program public health is being practised more effectively in Utah, and industrial hygiene takes on its real meaning—that is, health promotion among workers. In all of this work in Utah excellent coöperation has been received from organized labor, industry, the medical profession, and, especially, from the Industrial Commission.

The U. S. Public Health Service has always recognized that there are other agencies in federal and state government that are concerned with industrial hygiene problems. For this reason, it has in its own relations with federal agencies striven for a joint approach to the problem and has urged a similar activity on the part of state agencies. That such arrangements in the promotion of industrial hygiene activities are sound and practicable is amply demonstrated in the official relationships which now exist in several states, and notably in such states as California, Wisconsin, North Carolina, Utah, and Rhode Island. For example, in the State of California the Industrial Accident Commission furnishes the Industrial Hygiene Service of the State Health Department with copies of all occupational diseases reportable by law to the former agency. These are investigated by the health department. In addition, the factory inspectors of the Commission call upon the Industrial Hygiene Service to make technical investigations of potential health hazards in industry. Written copies of the results of such investigations are furnished to the Industrial Accident Commission for action, since it is this latter agency which is charged by law to enforce rules and regulations designed for the protection of the health of workers. Practically identical relationships exist in Wisconsin. In this

state a physical examination program was recently organized by the Industrial Commission in collaboration with the Industrial Hygiene Division of the Wisconsin State Board of Health.⁴ This plan appears to be an excellent approach to medical control of industrial health hazards which, coupled with engineering control, should go a long way in the prevention of industrial diseases.

Last year, I also emphasized the importance of supplementing our present information on occupational diseases and accidents with a knowledge of absenteeism with respect to frequency, duration, and cause in each numerically important occupational group in a working establishment. At that time it was indicated that such data will serve to reveal to the management and the public health worker the type of action which should be taken to obtain the maximum reduction in the amount of time lost from work on account of disability. Although in the short time which has elapsed it is not possible to present any specific statistics, it is gratifying to state that one large industrial concern, employing several hundred thousand workers, has inaugurated a plan of reporting occupational morbidity. In addition, several states have also undertaken this activity in cooperation with industry. To assist in collecting such data, the Division of Industrial Hygiene of the National Institute of Health has developed a simple report card, which can also be used as a punch card for the analysis of the reports, and has prepared a manual indicating how the data should be collected and recorded.

In inaugurating industrial hygiene programs the various states and cities first undertook to define the problem in each locality. This definition was attempted through the medium of the industrial hygiene survey of potential exposures and by an evaluation of pres-

ent health services in industry. Today, practically all of the states engaged in industrial hygiene work have completed these surveys and are now actively engaged in controlling the health hazards revealed by these studies. The Division of Industrial Hygiene of the National Institute of Health is at present completing a summary of the various state surveys and will soon publish information on the exposure of approximately $1\frac{1}{2}$ million workers in 17,000 plants to various materials and conditions of public health significance. Preliminary data show that only one-fourth of the workers in these plants had the services of a full-time safety-director, and that only 15 per cent of the workers were provided with a plant physician, and about one-third had the services of a full-time plant nurse. One interesting finding with reference to present health service facilities in these 17,000 plants deals with sickness records. The survey data show that nearly half (45.4 per cent) of the workers were in plants maintaining sickness records, indicating that some information on the extent of so-called "non-occupational" illnesses in industry is at hand.

With reference to the exposure of these workers to various materials and conditions of public health significance, it was possible to estimate the number of workers which could be expected to be exposed in all United States industry. For example, nearly $1\frac{1}{2}$ million people are exposed to the hazards from carbon monoxide gas and $\frac{3}{4}$ million persons to lead and its compounds. Slightly more than 1 million persons are exposed to the inhalation of silica dust, while the most frequent exposure is to agents capable of causing dermatitis.

Some information was also obtained on the control measures now being employed with reference to some of these exposures. For example, in connection

with silica dust, 93,244 persons were found to be exposed, and of this number 14 per cent of the workers were provided with local exhaust ventilation. Wet methods were frequently employed, and so were respirators. Although the degree of protection afforded by these various measures was not evaluated at the time of the survey, still we have an indication of the extent to which steps have been taken to ameliorate conditions, and from the brief data presented it appears that much needs yet to be done in this field.

Two years ago, the various individuals engaged in industrial hygiene activities in government services banded together to form the National Conference of Governmental Industrial Hygienists.⁵ The objects of the Conference are to promote industrial hygiene in all its aspects and phases, and to co-ordinate such activities in official federal, state, local, and territorial organizations. This organization has been instrumental in encouraging the interchange of experience among industrial hygienists in such official organizations. In April of this year, the second annual Conference was held, of which an entire day was devoted to reports from 11 committees. To give one an idea of the work being undertaken and actively pursued by this Conference, I should like to list the various committees which reported this year and which have been actively continued. One committee is engaged in the study of methods in appraisal of industrial hygiene problems in the localities, while another is concerned with the relationship of industrial hygiene activities to industry, labor, the medical profession, and other agencies. There is a committee on technical standards and this committee has been organized into several sub-committees. A committee on industrial hygiene education also reported, while the committee to study methods of securing effective and uni-

form reporting of occupational diseases and other illnesses among workers was able to contribute substantially to this subject. Other committees are those dealing with administrative development of industrial hygiene in the state through local departments of health, a committee on industrial health codes, one on the study of industrial hygiene legislation, and a committee on industrial hygiene personnel. And, finally, a committee was organized to develop a standard system of reporting industrial hygiene activities.

In connection with some of the well established public health functions, suitable forms for recording progress have been developed and found practicable. No such established technique has been developed for industrial hygiene, since it is only in the last two or three years that our various state health departments have become active in this field. Without going into a discussion of what constitutes a satisfactory report of accomplishments or progress at this time, suffice it to say that after deliberate study some simple forms were developed to be used as a starting point for the recording of activities and achievements. In developing these forms it was kept in mind that a state industrial hygiene program is essentially concerned with application of research and certain educational functions. In considering the work of an industrial hygiene division, experience has shown that services are rendered because of requests, because of a long range program, and as a result of reports of morbidity which may be made to the health agency. The forms to record such information have recently been given a trial and appear to work satisfactorily. In fact, these forms have the advantage of calling to the attention of the industrial hygiene administrator some of the shortcomings of the program.

At this point mention should be

made of a few of the accomplishments in our newly formed industrial hygiene units. In one state, functioning on a limited budget of \$10,000, and with only the services of 1 physician and 1 engineer, it was possible to control silicosis and other dust hazards effectively in the granite, slate, talc, and asbestos industries in that state. All this was made possible by the active participation and coöperation of industry and labor. As a result of these combined efforts more than \$100,000 worth of dust control equipment has been installed in various granite cutting sheds in this state, and approximately \$25,000 has already been spent for the control of the dust hazard in granite quarries. As a result of the efforts of the work of this small unit it may be truthfully said that the dust hazard has been controlled for nearly 4,000 workers in this state. This is, indeed, a worthy achievement.

In another state, several thousand physical examinations of workers in dusty trades brought out many defects in health among the workers, and steps were taken for the correction of these physical defects. In addition, the control of the working environment contributing to some of these ailments was also effected. In still another state many industries were investigated and as a result of some of these studies, approximately 5,000 persons may now be said to be working under more healthful conditions. In one of our New England states routine investigations were made in plants housing several thousand individuals and improvement made in the working environment, so that health hazards were eliminated. Furthermore, studies as a result of a planned program were also undertaken and remedial measures instituted. In the foundry industry in this state approximately \$300,000 were expended for control measures as a result of recommendations made by the industrial

hygiene unit. All told, some 14,000 persons were in these industries, so that working conditions for these people are now greatly improved. This particular industrial hygiene unit also carried on an extensive consultation service on numerous industrial hygiene topics.

So far I have sketched for you two of the features of an industrial hygiene program, namely, that of application of research and educational activities. I have said nothing about the first part of such a program, that is, fundamental research. Those of you who have been following the literature on the subject of industrial hygiene, have probably noticed the tremendous amount of information now being published in the field of industrial hygiene. These contributions come to us from industry, insurance companies, universities and governmental agencies. The industrial hygiene building of the National Institute of Health was recently completed, so that all of the activities in industrial hygiene of the U. S. Public Health Service are now together. It is hoped that with the states carrying more of the burden of the preventive phases of industrial health, the Service will have more time to devote to research.

In closing this brief and incomplete summary of some of our accomplishments, I should like to state that we have gone far in the field of medical control, in toxicology, and in engineering control of health hazards in industry. There was a time when all discussions of engineering control of occupational diseases were always prefaced by the remarks that there is a paucity of data on the subject. Today, we can proudly say that we have accumulated a considerable amount of information in the last four or five years. This body of information is being applied successfully in many of our states, and today we feel confident that there are really very few exposures which are impossible of control.

PROSPECT

Although it has been very gratifying to discuss the various achievements in industrial hygiene in the last year or two, we must not think that we can rest upon our laurels. Industrial hygiene, as a special field in public health, is relatively in its infancy. Although we can truthfully say that the lag between the knowledge of how to control industrial health hazards and the degree of success in applying this knowledge is rapidly diminishing, much still remains to be accomplished.

In discussing prospects in industrial hygiene, no attempt will be made to paint a glowing picture of the future in this field, but to indicate briefly some of the problems confronting us and what may be done to solve them.

One of the primary needs today is a sufficient number of trained personnel. It is important, therefore, that institutions for teaching of industrial medicine and the methods employed in the engineering control of health hazards in industry be organized as quickly as possible. The Division of Industrial Hygiene of the National Institute of Health has attempted to overcome the lack of trained personnel by presenting brief courses in industrial hygiene and by arranging for in-service training in the various state units for the personnel now entering the field. These measures are merely stop-gaps and not very satisfactory, so that serious consideration should be given by some of our schools of public health and medical schools to developing a course in industrial hygiene.

All of the states now engaged in industrial hygiene activities spend approximately $\frac{3}{4}$ million dollars. It is evident that with the numerous problems confronting these various units, this is far too small a sum and that more money will have to be appropriated for this work. In addition, our observations and reports which we re-

ceive from the various states indicate that there is a lack of trained personnel to carry on the various activities. For example, one of the problems which confront most of the states is the reporting of occupational diseases and other illnesses. In some of the states the reporting is now much better than it was. In one state, for example, some 5,000 reports of occupational diseases were sent in to the state health department last year. However, but a small number of these reports were investigated, since no personnel was available for the all-important follow-up work. I believe we should all strive to increase our budgets and our personnel and that the various legislatures in the states be urged to appropriate sufficient funds to carry on this important activity in a manner commensurate with its importance.

Mention has already been made of the active interest on the part of industry in the field of industrial hygiene. After all, corrective measures in industry are accomplished by private effort and private funds. The important task for any industrial hygiene administration is to persuade industry to solve its own health problems. The official agency mainly serves in aiding industry to evaluate its problems, suggests ways and means for their control, develops standards of good practice, furnishes technical guidance, and conducts educational programs. Industry has not been slow in accepting its share of the responsibility and is coöperating with official agencies. Recently, through the American Association of Industrial Physicians and Surgeons, a committee was organized to study present industrial hygiene facilities in representative industrial establishments for the purpose of evaluating these facilities and developing standards which would serve to expand and improve present programs.

The question of good practice codes

has received attention of late among our trade associations and state industrial hygiene units. A good practice code for the elimination of a hazardous condition in an industry should do more than set forth the desirable conditions under which work may be carried on, but should also instruct the management as to how these desirable conditions may be achieved. An example of the latter type of code is the U. S. Public Health Service milk ordinance and code. This particular publication contains a 13 page ordinance while the code itself, which gives the information as to how the desirable items of the ordinance may be complied with, consists of nearly 100 printed pages. The codes of the American Foundrymen's Association are excellent examples of what may be done to aid management to clean house and provide a safe and healthful working environment. More such codes are greatly needed.

I have already mentioned the trend today in industrial hygiene, showing that more and more local health organizations are beginning to participate in this important field of public health and I have also indicated how the industrial hygiene program in a state can be integrated with other health services in a health department, with other governmental agencies, medical organizations, labor, industry, and nonofficial agencies. I would urge all public health administrators to consider seriously this important phase of the program and to do all that is possible to devise a plan which will coördinate the activities of all the agencies interested in, and responsible for, industrial hygiene in their communities.

Our problems in industrial hygiene will be constantly increasing rather than diminishing, in spite of all our efforts in the field. This is largely due to the fact that added responsibilities are given to administrators due to a variety of causes. With increased

mechanization in industries, with the use of old and new chemical compounds in many of our processes, the responsibilities given us by legislation, and those which might be added in case of war, all of these factors, and many more too numerous to mention, will add greatly to the burden of industrial hygienists in the future. I believe that all of us should have our programs so planned as to be able to meet these exigencies as they arise.

So far I have been discussing the prospect of industrial hygiene from the administrative point of view. There are, of course, many technical problems which are also in need of solution. In the field of personal hygiene we are greatly in need of more sensitive methods of diagnosis and we are especially in need of tools which will enable us to detect incipient cases of disease before real damage occurs. In the environmental field we have made great strides in developing more precise sampling instruments and more precise methods of analysis, as evidenced by the papers to be presented here this week. However, as our increased engineering knowledge enables us to control environmental conditions to a point where only small amounts of toxic materials remain in the air, it will be necessary to develop more precise sampling and analytical methods so that we can detect these minute amounts. One could, of course, argue that our present methods enable us to detect the so-called threshold limits, so that we need not worry about finding materials below this toxic limit. However, most of these limits are merely tentative, and increased medical knowledge may show that our standards today may be far too dangerous tomorrow. For that reason we should continually strive to improve our sampling and analytical technics in engineering control of industrial health hazards. This Section has a committee on Chemical

Procedures in Air Analysis and yesterday we heard an excellent report on the work in progress. It is hoped that research can be developed on the subject of chemical procedures in the determination of toxic materials in industry, and that as a result of such research and the work of this committee and others, a handbook on standard methods may be developed.

I have attempted to sketch briefly some of our accomplishments and a few of the problems and needs in industrial hygiene. I think we can be heartened by the actual progress made and the prospects before us. The members of this Section have made important contributions for the past 25 years to the administrative and technical phases of industrial health and I am convinced that we must continue to meet the challenge of new responsibilities, and I am sure that we will do so. Industry is cognizant of the fact that it pays to control and prevent industrial health

hazards. Labor is now sufficiently well informed, organized, and articulate to demand safer and more healthful working conditions. We have at hand the tools and the information necessary for creating healthful working conditions and for improving the health of workers. It seems to me that under such favorable conditions we should all strive for the goal before us so that we can bring positive health to the industrial worker.

Professional Training Courses

DR. C. C. P. ANNING, Medical Officer of Health for Benoni, South Africa, referring to the content of university courses for professional training in public health says, "The public health courses . . . include much study in sanitary details about air pollution and plumbism, leprosy and tapeworm infection, yet no time at all is given to sociology, to economics, to social psychology or social anthropology, subjects which form an essen-

tial background to the work of the health officer today. There is no training given even in the art of health education, though perhaps it is felt that anyone with an ounce of bounce can put health education across.

As Sir Stephen Tallents said the other day, 'There is an idea that publicity is a sloppy kind of business that requires little forethought, little planning, little pains and little organization.'

Sylvatic Plague*

KARL F. MEYER, PH.D., M.D., F.A.P.H.A.

Professor of Bacteriology, Director of the George Williams Hooper Foundation, and Director of Curricula in Public Health, University of California, San Francisco, Calif.

THE Executive Committee has held no meetings. No problems were submitted for consideration. In fact, it is apparent that without further more accurate knowledge relative to the epidemiology of plague infections in rodents, no more significant and effective suppressive measures than those in use can be devised. An informative statement relative to diseases of rodents has been mimeographed, and at least 500 copies distributed throughout the state of California as well as a limited number in other states. As a whole, the pamphlet has been well received and has not aroused the reaction among chambers of commerce which had been predicted. Vacationists and hunters are quite familiar with the inherent dangers of exposure to rodents. Judicious publicity in the form of talks and in the daily press keeps the layman well informed and continuously in touch with the progress of the various findings.

EPIDEMIOLOGICAL OBSERVATIONS DURING 1938 AND THE FIRST HALF OF 1939

Again the Committee on Sylvatic Plague has collected, in coöperation with the State Health Officers and Dr. C. R. Eskey of the U. S. Public Health Service, statistical data concerning the

extent of human and rodent plague. The pertinent data may be summarized as follows:

I. HUMAN PLAGUE

No human cases of plague have been recognized or reported. In this connection it is worth noting that several reports and laboratory observations attest to the beneficial effect of prontosil or sulfapyridine in the treatment of human plague infections. Carman (1938) reported from East Africa the administration of prontosil in 6 cases, 3 of which recovered. Vine (1938) in a small epidemic in the Nilgiris treated 3 cases and all recovered. In the experiments of Schütze (*Lancet*, Feb. 4, 1939, p. 266) sulfapyridine proved to be the most efficacious of the newer preparations in chemotherapy of *Pasteurella pestis* infection of rats and mice.

II. RODENT PLAGUE (ANATOMICAL AND CLINICAL) AND INFECTED FLEAS COLLECTED FROM WILD RODENTS

The data pertinent to the survey activities are summarized in Tables I and II. The committee is indebted to E. T. Ross, California State Department of Public Health, for the summary in Table I and to Dr. C. R. Eskey for the report which is reviewed and condensed in Table II.

* Fourth Report of the Chairman of the Sylvatic Plague Committee of the Western Branch American Public Health Association. Read before the Tenth Annual Meeting in Oakland, Calif., July 23-28, 1939.

In California the collection and autopsy of 10,863 rodents in 301 different areas yielded 6 *C. beecheyi* squirrels with anatomical markings indicative of plague. It is of interest to note that for the first time since the existence of plague has been recognized through the appearance of human cases or the demonstration of fleas infected with *P. pestis*, grossly diseased squirrels were found in two counties. El Dorado County on the shores of Tahoe region, proved to harbor plague through one human infection in 1936 and another in 1937, produced 2 such squirrels.

In 1933 San Bernardino County was suspected of being a sylvatic plague area, but annual surveys yielded only infected fleas until in 1938 when 4 Fisher squirrels with definite plague lesions were found. Again the injection of squirrel organs into guinea pigs in the form of pools was proved valuable. The number of rodents included in a pool varied from 5 to 12 in the 6 collections which proved to be infected

with *P. pestis*. The advantages of examining fleas collected from apparently healthy squirrels is equally attested by the demonstration of infected vectors in 17 collections. Thus the surveys disclosed 16 new areas as sylvatic plague foci. The existence of latent plague in golden mantled squirrels in Plumas County has been established.

In 1939 an old focus in Ventura County showed renewed activity. Three young *Beecheyi* squirrels with enormous splenic tumors, and no buboes or other markings were proved to be the victims of an acute plague septicemia. Infected fleas have recently been found in Contra Costa County.

If one surveys with an open mind the enormous amount of work so faithfully carried out by the survey crews, and evaluates the benefit derived from these efforts, one wonders if the time has not arrived to review and re-orient the procedures. That sylvatic plague exists in California and is widely distributed, is now an established fact.

TABLE I

California Counties in Which Plague Was Demonstrated During 1938

Plague Demonstrated in 30 Specimens as Follows:

County	Individual Rodents	Pools of Rodents	Rodents in Pool	Pools of Fleas	Fleas in Pools	Number of Foci	Totals Collected	
							Rodents	Fleas
El Dorado	2	2	26	3 (new)	937	1,053
Fresno	..	2	12	2	91	3 (new)	5,004	12,730
Plumas	..	1	10	1 (new)	237	163
San Benito	..	1	10	2	394	2 (new)	965	8,429
San Bernardino	4	1	5	6	361	7 (new)	2,301	4,378
Santa Clara	1	75	1 (old)	726	4,758
Santa Cruz	1	1	5	4	136	3 (old)	693	4,226
	7+	6+	42	17+	1,083	20	10,863	35,737

Other Counties Surveyed

Alameda, Contra Costa, Kern, Lassen, Los Angeles, Madera, Mariposa, Monterey, Marin, Merced, Placer, San Mateo, San Luis Obispo, San Joaquin, Stanislaus, San Francisco, Sonoma and Tulare

Rodents collected 16,172
Fleas collected 69,114

* New infections

Furthermore it is equally recognized that it may appear in epidemic proportions any time and anywhere in the state provided certain conditions, as yet inadequately understood, are conducive to an increased distribution of the infective agent. How to prognosticate the occurrence of these epizootics with their inherent dangers to man is a complex problem which requires field investigations and analysis by diverse groups of mammalogists and entomologists.

It has been repeatedly emphasized that sylvatic plague is everlasting and that the available knowledge suggests

continuous vigilance in preventing contact of the rat population with the diseased wild rodents. In California this type of suppressive work has been effectively carried out by the State Department of Agriculture. At least 3,700,000 acres in which sylvatic plague has been demonstrated have been treated with poison grains, carbon bisulphide and miscellaneous materials. The estimated cost of ground squirrel suppression during a year, for all purposes and agencies, is \$614,000. The outlay of WPA funds approximates \$58,500. It is to be hoped that the advantages gained may be maintained by slightly

lessened activities. However, experience has taught that with the present-day knowledge, little permanent effect may be anticipated. Here again, more research is doubtless needed in order to accomplish the desired protection without the expenditure of large sums of money.

The survey activities by the U. S. Public Health Service as shown in Table II have disclosed a number of significant facts:

1. Sylvatic plague exists now in 10 of the 11 states. In 1938 it has conclusively been demonstrated in various epizootics of prairie dogs and squirrels (fleas) in Arizona, New Mexico, and Wyoming. Thus sylvatic plague has crossed the Continental Divide and the possibility of extension in the Rio Grande deserves continuous observation.

2. Extension into new counties has been observed in Idaho, Montana, Oregon, Utah, and Washington. It is significant that in a few instances the presence of sylvatic plague announced itself in the form of epidemics of the

rodents with a notable mortality, and thus attracted the attention of the representatives of the Biological Survey. The splendid coöperation offered by this service to the sylvatic plague studies deserves special comment.

3. New species of rodents such as kangaroo rats (Mexico), cottontail rabbits (Washington), and the pack rats of the desert area of Nevada have been found as hosts of *P. pestis*.

4. The collection and inoculation of guinea pigs with pools of fleas, lice, and ticks has again yielded more information than the examination of the carcasses of rodents shot or trapped. If one excludes from consideration the tissue examinations made on dead or sick rodents collected in actively epidemic areas (New Mexico, Washington, and Wyoming), the benefit derived from these tests appears definitely limited. Without mass inoculation of fleas sylvatic plague surveys cannot be considered modern. Although the majority of health officers accept the demonstration of infected fleas removed from healthy rodents as *de jacie* evi-

TABLE III

Rodents Known to Suffer from Spontaneous Plague

Sciuridae	Washington ground squirrel	<i>Citellus Washingtonii</i> (Washington)
	Richardson's ground squirrel	<i>Citellus Richardsonii</i> (Montana)
	Wyoming ground squirrel	<i>Citellus Richardsonii elegans</i> (Wyoming, Montana)
	Uinta ground squirrel	<i>Citellus armatus</i> (Idaho, Utah, Washington, Wyoming)
	Oregon ground squirrel	<i>Citellus beldingi oregonus</i> (California, Oregon)

	Mohave woodrat	<i>Neotoma fuscipes mahavensis</i> (Nevada)
	Desert woodrat	<i>Neotoma desertorum</i> (Nevada, Utah)
	Kangaroo rat	<i>Dipodomys ordii</i>
Leporidae	Cottontail rabbit	<i>Sylvilegus nuttallii</i>

dence of the existence of sylvatic plague in the area, there is still some hesitancy on the part of others to accept this interpretation. The committee has already expressed its opinion in 1937 and again in 1938 in the sense that the recognition of either infected rodents or fleas constitutes conclusive proof of the presence of sylvatic plague in the respective area and that control measures must be applied to this particular region.

A survey concerning sylvatic plague was undertaken in 1938 in the Province of British Columbia in coöperation with the Provincial Department of Health and the Dominion Department of Pensions and National Health. The survey activities covered examination of *Citellus columbianus* and *Marmota flaviventris avara*. The inoculation of tissues and pools of fleas yielded negative findings for *P. pestis* on guinea pigs. Thus no sylvatic was discovered. Similarly rat collections in Vancouver and New Westminster were made. The total flea index was 0.91. A high percentage, 98 per cent, of *Rattus norvegicus*, was observed. *P. pestis* was not discovered in any of the tissues or flea specimens submitted for examination.

In view of the survey studies made throughout the Western States since 1908 and particularly since 1934, the rodents listed in Table III are known to suffer from spontaneous plague.

III. SCIENTIFIC INVESTIGATIONS

1. *Vector efficiency and plague transmissions*—Dr. C. R. Eskey has continued his studies on the transmission of plague by fleas from wild rodents. He has been able to infect 26 species of wild rodent fleas with plague transmitted by bites of 13 species found on wild rodents. These fleas included nearly all of the common species encountered in the West.

2. The fleas on prairie dogs in

Arizona and New Mexico have been studied by William L. Jellison. Three closely related species—one new one, *Opisocrostitis tuberculatus cynomysus*—have been identified. In several localities the prairie dogs were heavily infected with human fleas.

3. William L. Jellison of the Rocky Mountain Laboratory, U. S. Public Health Service, has studied the possible relationship of flesh-eating birds to the epidemiology of sylvatic plague in Montana. He found that predatory species may serve as accidental hosts of rodent fleas. In particular the burrowing owl (*Scototyto cammularia*) deserves consideration. Certain forms of predatory birds fed plague-infected guinea pig tissues were consistently infectious, while a few species fed plague tissues were non-infective.

4. Under the guidance of Drs. T. I. Storer, M. A. Stewart, and C. M. Wheeler, a field crew of 2 to 3 men appointed by the State Department of Public Health has collected data concerning the activities of rodent species (particularly *Citellus beecheyi*) and the distribution of flea species. Trapping operations were initiated at Bass Lake, Madera County, in order to obtain information which may be of value in the planning of suppressive measures relative to recreational areas. The observations covering one year are being analyzed.

5. Studies on the host-parasite relationship to *P. pestis*, the susceptibility and immunity of Beecheyi and Richardson squirrels, and investigations on the vector-parasite cycle are in progress at the new sylvatic plague laboratory of the George Williams Hooper Foundation, University of California, endowed by the Rosenberg Foundation. Although the investigations are in active progress it is worth noting that in some series only 50 per cent of the squirrels trapped in regions not proved to be plague infected succumbed to intra-

cutaneous injections of from 9-23,000 *P. pestis*.

Types of Tubercle Bacilli in Lesions of Garbage-Fed Swine

WILLIAM H. FELDMAN, D.V.M.

*Division of Experimental Medicine, The Mayo Foundation,
Rochester, Minn.*

THE feeding of garbage to swine is a fairly common practice that is justified in most instances by: (1) being a practical and expedient manner for the disposal of unused food or food that is unsuited for human consumption, and (2) by being an economical source of food for the feeding of swine. It is obvious, of course, that the indiscriminate collection of garbage and feeding it to swine in an uncooked state provides opportunity for the transmission of certain bacterial and parasitic diseases.*

There are available several reports in which human tubercle bacilli have been recovered from the tuberculous lesions of swine that had been fed uncooked garbage. There are, however, comparatively few reports as to the frequency of the different types of tubercle bacilli responsible for lesions of tuberculosis in garbage-fed swine. That data might be secured concerning this problem as it exists in a large metropolitan area, a study was made of material obtained from one of the abattoirs in South St. Paul.

MATERIAL AND METHODS

Only swine that were definitely known to have been fed garbage were included in the study. The identity of such animals was ascertained at the time of purchase by the management of the abattoir and consequently it was possible to slaughter the animals separately from the "regular kill." This procedure facilitated the post-mortem examinations by the federal meat inspectors who collected the specimens subsequently utilized for laboratory examination. Attempts to secure information as to the origin of the garbage fed to the swine were unsuccessful.

The 11 lots of swine were slaughtered over a period of approximately 4 months. No selection of the lots of swine included in the study was exercised. All garbage-fed swine presented for slaughter during the period of the investigation were included in the study.

The 11 lots of swine comprised a total of 264 animals. By the usual careful post-mortem examination 75, or 28.4 per cent, of the carcasses were considered by the meat inspectors to contain gross lesions of tuberculosis. The lesions in practically all instances were classified as "slight" with the disease limited to the lymph nodes of the head and neck or the mesentery. The tissues obtained from the 75 swine

* Many of the problems associated with the feeding of garbage to swine have recently been presented by Germanio. In Canada the feeding of swine with garbage, swill, meat scraps, offal, or vegetable refuse, either raw or cooked, obtained elsewhere than on the premises where fed, is prohibited unless a license has first been obtained from the Veterinary Director General.¹⁴

that were considered at necropsy to be tuberculous may be briefly summarized as follows: mesenteric lymph nodes from 27 swine, submaxillary lymph nodes from 19, cervical lymph nodes from 14, portal lymph nodes from 1 hog. In 14 specimens from 14 swine the anatomic situations from which the lymph nodes were obtained were not designated. In all cases except 2 only one specimen was received from each carcass. In 2 cases both a submaxillary and a mesenteric lymph node were received, but only the mesenteric nodes were utilized.

The character of the lesions presented by the respective lymph nodes was as follows: multiple caseous abscesses 48; caseocalcareus 16; single caseous 6; hyperplasia with minimal necrosis 1. Lymph nodes from 4 cases failed to show definite gross evidence of disease. Most of the lesions were small and many appeared to have been of recent origin. All of the caseocalcareous lesions showed variable degrees of encapsulation and some peripheral fibrosis was noted in many of the lesions that were caseous.

The respective specimens were forwarded to the laboratory in dry borax, each specimen in a separate container. When received, the tissues were immersed in boiling water for 5 to 10 seconds to remove the borax and to reduce the possibility of extraneous contamination. A portion was removed for subsequent histologic study and the most likely portions of the rest of the material were emulsified in sterile sodium chloride solution.

The respective emulsions were used to prepare cultures; both glycerinated and nonglycerinated egg-yolk agar mediums being used.* For the elimination of other than mycobacteria that might be present, those portions of the respective emulsions that were cultured

were treated with 5 per cent oxalic acid as suggested by Corper and Uyei. The amount of emulsion used for culture was 2 cc. After preparing the emulsions as described in detail elsewhere 8 slants of medium—4 glycerinated and 4 nonglycerinated—were inoculated and incubated at 37.5° C. for a period of 10 weeks unless positive results occurred sooner.

Each emulsion prepared from the respective lymph nodes was used also to inoculate two guinea pigs subcutaneously, each animal receiving 1 cc. Unless dying before, the guinea pigs were maintained for 8 weeks, when they were killed for necropsy.

In these instances in which acid-fast bacteria were not obtained in culture before the guinea pigs injected with portions of the same emulsion died or were killed, the spleen of one or of both guinea pigs was cultured for tubercle bacilli, whether or not lesions of tuberculosis were discernible.

After cultures had been obtained either direct from the original material or from the spleens of the guinea pigs, the physical character of the different bacterial strains was noted and the bacillary type of each culture determined by the injection of two additional guinea pigs and two rabbits. The dose used in most instances was 0.01 mg. The guinea pigs were injected subcutaneously and the rabbits intravenously. The period of observation for the guinea pigs was 8 weeks; for the rabbits 90 days.

RESULTS

The results of the investigation are summarized in Table I. As may be noted, tubercle bacilli were demonstrated and cultures eventually secured in 47 of the 75 lesions obtained for study. When the 47 strains were typed to distinguish the bacillary type of the respective cultures, 12, or 25.5 per cent, proved to be of the human type while

* The medium was originally described by Capaldi and more recently by Herrold.

TABLE I

Summary of Results of Study to Determine Types of Tubercle Bacilli in Lesions of Tuberculous Garbage-fed Swine

Lot	Number of Swine	Retained for Tuberculosis	Tubercle Bacilli Demonstrated	Type of Tubercle Bacilli *	
				Human	Avian
1	32	12	8	6	2
2	24	7	5	3	2
3	27	4	3	0	3
4	23	4	4	0	4
5	26	5	1	0	1
6	16	9	5	0	5
7	21	5	1	0	1
8	30	8	7	0	7
9	13	5	5	3	2
10	21	4	2	0	2
11	31	12	6	0	6
Totals	264	75	47	12	35

* Type determined by tests of pathogenicity.

35, or 74.5 per cent, were of the avian type. It seems significant that in no instance were bovine tubercle bacilli demonstrated.

Human tubercle bacilli were isolated from the lesions of only 3 of the 11 lots of swine. The total number of animals in the 3 lots was 69. Twenty-four of the 69 carcasses had been "retained" on account of tuberculosis at the post-mortem examination and tubercle bacilli were subsequently demonstrated in 18. Twelve of the cultures were identified as human tubercle bacilli and 6 as being of avian type.

It is of interest that tubercle bacilli were demonstrated as present in only 47, or 62.7 per cent, of the 75 lesions that were considered as tuberculous by the meat inspectors. The difference in the laboratory findings compared to those of the gross examination may be due to several factors such as: (1) inadequacy of the methods used to demonstrate tubercle bacilli; (2) the bacteria may have been dead or avirulent or too few in number to initiate growth on culture medium or produce lesions of tuberculosis in guinea pigs; and (3) some of the lesions in which tubercle

bacilli were not established may have been due to causes other than tubercle bacilli. Many of the lesions were minimal in extent and some at least were grossly without convincing characteristics of the lesions of typical tuberculosis.

COMMENT

The susceptibility of the hog to each of the three types of the tubercle bacillus makes the incidence of tuberculosis in swine a fairly satisfactory index as to the amount of bovine, human, and avian tuberculosis in a given community. It is recognized, of course, that the possibility for exposure constitutes an important factor. It is conceivably possible by strict hygienic measures to rear swine free of infection with tubercle bacilli, even though the incidence of tuberculosis in human beings, fowl, and cattle may be high. However, the unsanitary practices frequently followed in rearing and feeding swine for the market usually provide opportunities for contact with one or each of the three types of tubercle bacilli, providing tuberculous fowl, cattle, or human beings exist on the

same premises with the swine, or the animals are supplied foodstuffs containing tubercle bacilli.

Although the susceptibility of swine for avian and bovine tubercle bacilli has been adequately established by many competent investigators, the infectiveness of human tubercle bacilli for swine is not as well understood.* A brief review of the available reports on this question would therefore seem appropriate.

Dinwiddie^{6,7} of the Agricultural Experimental Station of Arkansas in 1899 and 1900 contributed two noteworthy reports on the question of the relative virulence for domestic animals of human and bovine type of bacilli and included a comprehensive review of the literature. He mentioned the experiments of Blumberg who succeeded in infecting swine with sputum from tuberculous human beings. Dinwiddie also made reference to Wesener's review made in 1885 in which it was concluded that of the 71 animals used in feeding experiments, guinea pigs and swine were the species most easily infected with infectious material from tuberculous human beings.

Dinwiddie also reported the results of his own studies in which swine were exposed to experimental infection with human and bovine tubercle bacilli. Tuberculosis of the submaxillary and mesenteric lymph nodes followed the ingestion of tuberculous sputum in 2 of 6 animals tested. A more severe tuberculosis followed the intraperitoneal injection of swine with infective sputum or cultures, and Dinwiddie concluded that a progressive and even fatal tuberculosis may develop in swine following the ingestion of sputum containing tubercle bacilli. Although Dinwiddie expressed the opinion that infection

of swine with human tubercle bacilli is insignificant compared to the greater possibility for infection with bovine tubercle bacilli, he mentioned that the experimental evidence did not preclude the possibility of the occasional occurrence in swine of tuberculosis from human sources.

Orth in 1902 was quoted by Salmon as having tested the virulence of human tubercle bacilli for swine. The strain which was used to inoculate 2 swine intraperitoneally and intratracheally was obtained from a case of "phthisis cavernosus" in a human being. The intraperitoneal inoculation failed to induce demonstrable signs of tuberculosis while the animal that had received the infective material intratracheally showed extensive disease in the right lung and in the thymus gland when examined at necropsy 5½ months after inoculation.

Dean and Todd (1902) conducted a series of experiments designed to ascertain whether the virulence of human tubercle bacilli for calves might be increased by passage through other animals including swine. The infectious material used was tuberculous sputum. This was used to inoculate 5 pigs subcutaneously, and in addition 3 pigs received tuberculous sputum by ingestion. Four of the animals inoculated subcutaneously died in 31 to 137 days, while the 5th was killed after 227 days. Severe and widely distributed lesions of tuberculosis were noted in each of the 5 animals. Those receiving the infective material by the mouth developed tuberculous lesions of the head and neck. The authors concluded that in contradiction to Koch's results, human tubercle bacilli are capable of producing in swine a rapidly fatal generalized tuberculosis.*

* The pathogenicity of avian tubercle bacilli for swine is considered in detail in the monograph by Feldman, W. H. *Avian Tuberculosis*. Williams & Wilkins, 1938, 483 pp.

* Dean and Todd gave a brief résumé of Koch's experiments in which 6 pigs were each fed daily for a period of 104 days, 15 cc. of sputum containing tubercle bacilli. In 5 of the animals the results were listed as negative and in 1 animal the

De Schweinitz, Dorset, and Schroeder^{9, 10} studied the comparative virulence for swine of tubercle bacilli obtained from both human and bovine sources. The test animals were injected subcutaneously, 4 strains of tubercle bacilli of human origin and one of bovine origin being used. Of the 8 animals injected, all but one showed generalized tuberculosis when examined at necropsy a few weeks to a few months later. The one exception was without evidence of disease when examined at necropsy approximately 5 months after being inoculated. The authors concluded in part that "certain tubercle bacilli of human origin possess quite as great pathogenic power for hogs as tubercle bacilli of bovine origin." Whether or not the tubercle bacilli of human origin used in the experiments of de Schweinitz, Dorset, and Schroeder were in reality tubercle bacilli of the human type might well be questioned. Three of the cultures used were obtained from the spleens of guinea pigs inoculated, in 2 instances, with tuberculous mesenteric nodes of children, and in the 3rd instance with a tuberculous nodule of the peritoneum of a child. The infective material used to inject 2 of the swine was listed as "human intestine (tuberculous)." In view of the prevalence of the bovine type of extrapulmonary tuberculous infection in children in the era (1904) when the report of de Schweinitz, Dorset, and Schroeder appeared, the bovine character of at least some of the tubercle bacilli that these authors used is not improbable even though the infective material was considered of human origin.

In a report published in 1909, Mohler and Washburn mentioned Bang's ac-

results were listed as "doubtful." Two pigs injected subcutaneously on one occasion with diluted sputum according to Dean and Todd showed only a localized tuberculosis after 100 days and 135 days respectively. When one considers that each swine in the series that Koch exposed to infection by ingestion received a total of more than 1.5 liters of tuberculous sputum, it is difficult to explain the failure of discernible lesions to develop.

count of the appearance of tuberculosis among hogs on a farm where the disease was not thought to exist previously. The infection was said to have resulted from the practice of tuberculous attendants spitting on the hogs' feed and about the premises. Mohler and Washburn also quoted a report of Kueser concerning the loss from tuberculosis of 11 3 months old pigs in a single litter that had presumably become infected from tuberculous sputum. The sputum accumulated during the night from a young woman fatally ill with tuberculosis and was thrown into the yard each morning. The young pigs had the liberty of the yard and it is presumed they came in contact with the infective material as a consequence.

Eastwood and Griffith (1914) mentioned that 2 pigs were fed tubercle bacilli of the human type that had been obtained from another swine and that in both of the animals tuberculosis of the submaxillary and mesenteric lymph node developed. There was also visible a slight dissemination of the disease to the organs.

In the annual report¹⁶ of the Bureau of Animal Industry, U. S. Department of Agriculture, for 1911 there occurs a brief account of tuberculosis occurring in hogs fed garbage from the kitchen of an asylum for the insane. Lesions from 6 animals were obtained for study and tubercle bacilli of the human type were demonstrated from 2, while in 4 hogs bovine tubercle bacilli were present.

The occurrence of tubercle bacilli of the human type in swine has been reported by several other investigators. Cobbett mentioned that the human type of tubercle bacillus had been found in swine in 4 instances. Butler and Marsch observed tuberculous adenitis in 26, or slightly more than 30 per cent, of 86 hogs in Montana that had been fed unsterilized garbage from a hospital in which a number of patients were

affected with tuberculosis. By adequate laboratory tests tubercle bacilli of the human type were demonstrated in several of the lesions. Stein investigated the types of tubercle bacilli responsible for the lesions in lymph nodes removed from 2 garbage-fed swine slaughtered at Denver, Colo. From 1 case avian tubercle bacilli were identified, and from the other case human tubercle bacilli were obtained.

Holth reported 3 cases of tuberculosis in swine due to human tubercle bacilli in Norway, and Pallaske mentioned that 3 cases of tuberculosis in swine due to tubercle bacilli of human type had been observed at the Kaiserlichen Health Office in Germany. Topacio typed 11 strains of tubercle bacilli isolated from tuberculous swine in the Philippine Islands and all were apparently of human origin. Tobel, Schaaf, and Roza reported the occurrence of tubercle bacilli of the human type in swine in the Dutch East Indies; 4 of 5 strains isolated were of human type. Cornell and Griffith investigated the incidence of the different types of tubercle bacilli occurring in the lesions of swine in London. Submaxillary lymph nodes from a total of 103 pigs were studied and tubercle bacilli were demonstrated from 95. Subsequent studies of the 95 strains indicated that 63 were of bovine tubercle bacilli, 31 were of avian tubercle bacilli, and 1 was of human tubercle bacilli.

Recently (1938) Danbolt and Brandt reported on the types of tubercle bacilli in swine in the region of Rogaland, Norway. The lesions from 160 tuberculous swine were investigated and avian tubercle bacilli were found in 80 per cent of the cases. Tubercle bacilli of the human type occurred in 17.5 per cent and bovine tubercle bacilli in 2.5 per cent.

The data that have accumulated concerning the pathogenicity of the human tubercle bacillus for swine indicate that

this microorganism is capable of infecting swine and that infection in most instances is introduced into the body by way of the alimentary tract. That garbage may at times contain tubercle bacilli seems to have been amply demonstrated. The presence of avian tubercle bacilli can in most instances be easily accounted for. Chickens affected with tuberculosis are not uncommonly dressed for food and the offal which frequently contains lesions of tuberculosis is usually disposed of by discarding it with the garbage. Unless such garbage is cooked, it constitutes a fruitful source of infection for other fowl and for swine.

The source of human tubercle bacilli in garbage probably is, in nearly all instances, infectious material from human beings affected with active tuberculosis. All uncooked garbage from tuberculosis sanatoria or from hospitals or private homes where tuberculous patients are cared for must be considered potential sources of tuberculous infection for swine. That apparently healthy food handlers may be sources of tuberculous infections is suggested by the report of Martin, Pessar, and Goldberg. By roentgenologic, sputum, and physical examinations these investigators found active pulmonary tuberculosis in approximately 2 per cent of presumably healthy food handlers in New York City. No doubt a large number of unknown and uncontrolled cases of active pulmonary tuberculosis exist in many large metropolitan areas. Expectorations and droplet infections from infected food handlers and patrons of public eating houses would of course be sufficient to provide possible sources of tuberculosis in swine-fed uncooked garbage. Other sources of tuberculosis of the human type of swine would be tuberculous employees of hog feeding establishments.

Swine affected with human tubercle bacilli are not necessarily a serious

hazard to human health provided the carcasses of such animals are subjected to a proper post-mortem examination by a qualified meat inspection service. Since the lesions in swine due to infection with the human tubercle bacillus are usually slight and localized and limited to one or several lymph nodes with no evidence of recent invasion of the systemic circulation, such carcasses are usually "passed for food" after the affected tissues have been removed. If the disease be severe and extensive the carcass is sterilized or condemned as unsuited for food.

It should be recognized, however, that lesions of tuberculosis in swine due to tubercle bacilli of the human type constitute a possible occupational hazard to slaughter-house employees and to meat inspectors. The latter especially are likely to come in contact with infectious material. Handling of diseased viscera and lymph nodes with the bare hands is a routine procedure and since the objective of the post-mortem examination is to discover evidence of morbid changes, the examination is carefully and thoroughly done. Manipulation of diseased tissues cannot be avoided, and the possibility for cutaneous infections exists.

Aside from the problem created in swine by infection with human tubercle bacilli the fact that such infections occur should be of interest to those concerned with the public health. If the dissemination of human tubercle bacilli is occurring in a community in sufficient numbers to produce tuberculosis in swine it is reasonable to believe that the source of such pathogenic organisms is a potential danger to other human beings. This thought should inspire an increased effort to search out subclinical cases of tuberculosis in order that the proper supervision may be exercised to prevent transmission of the disease to others who may be susceptible.

In this study the lack of certain pertinent data concerning the origin of the respective lots of swine precludes establishing definite proof that the tuberculous infections demonstrated were derived from the garbage that had been fed. The possibility that at least some of the infections were established before the period when the feeding of garbage was begun must be admitted. However, the likelihood of much of the infection being transmitted through the garbage seems a reasonable presumption.

SUMMARY AND CONCLUSIONS

In order to determine the types of tubercle bacilli in the lesions of tuberculosis in swine-fed uncooked garbage, a study was made of material obtained from a large metropolitan area. The total number of garbage-fed hogs examined at post-mortem examination was 264. Lesions of tuberculosis were established by the meat inspectors in 75, or 28.4 per cent. All lesions studied were those involving lymph nodes. By culture procedures and the inoculation of guinea pigs tubercle bacilli were demonstrated in 47. Subcultures were obtained of each of the 47 strains and the bacillary type of the respective strains was determined by tests for pathogenicity. Guinea pigs and rabbits were used. Thirty-five, or 74.5 per cent, of the strains were tubercle bacilli of the avian type, and 12, or 25.5 per cent, were tubercle bacilli of the human type.

The results suggest the following conclusions:

1. The failure in this study to demonstrate bovine tubercle bacilli appears significant and indicates the success achieved in eliminating tuberculosis from cattle.
2. It is probable that the garbage fed contained a considerable amount of offal from tuberculous fowl, indicating that tuberculous chickens are commonly sold for food.
3. It would appear that infective material from human beings affected with active

tuberculosis is not always properly disposed of, and that such material is a potential hazard to human health.

4. The presence in swine of tubercle bacilli of the human type constitutes an additional reason why unselected garbage should not be fed in an uncooked state to swine.

Methods of Poultry Evisceration and Packing and Their Relation to Health

C. E. EDMUNDS, D.V.S.

*Supervising Inspector, Dressed Poultry Inspection, Bureau of
Agricultural Economics, U. S. Dept. of Agriculture,
Chicago, Ill.*

ONE of the most important factors to be considered on the subject of recent methods of poultry evisceration and packing, and their significance to health, is that of post-mortem inspection of poultry at the time of slaughter, or prior to its being processed in a poultry canning plant. The inspection of poultry is not compulsory but is a service conducted under the supervision of the Bureau of Agricultural Economics, U. S. Department of Agriculture, and is available to interested poultry packers upon their voluntary application, and the payment of the cost of rendering the service to them. The importance and advantages of such inspection in the preparation of poultry for market is readily conceivable to the consumer and likewise to the many packers who utilize this service.

Since the time that poultry was produced and marketed as merely a by-product of the farm, there have been many changes. New methods have been employed in the breeding, hatching, raising, feeding, slaughtering, plucking, packaging, processing, storing, and transporting, through the channels of trade to the consumer, of this popular meat food product. These various changes have unquestionably been of great economic importance to the poultry industry and likewise have been an important factor in bringing

to the family table a more palatable, wholesome, and healthful food.

A number of years ago little attention was given to the preparation of poultry for market; it was simply slaughtered at convenient times and marketed regardless of condition and quality. Today, much of the live poultry to be marketed is delivered to a central poultry feeding station where it is carefully graded for condition. Birds showing evidence of disease or sickness are usually destroyed at this time. After this individual handling of the birds, they are placed in wire feeding batteries and kept on a milk feed mash diet for approximately a week. During this time of special care and diet, the fibers of the meat become soft and of finer texture and much improved in flavor, and the birds make considerable gain in weight. As they are constantly watched by the feeders, any birds appearing to be in off-condition are immediately destroyed or isolated from the healthy birds. At the conclusion of the feeding period they are ready for slaughter.

The new methods of slaughter and dressing which are now employed are a great improvement over those which were used when all of the day's kill was immersed in the same tank of scalding water to make feather plucking easy. After slaughter and plucking, the birds are hung on racks in a

cooling room so that the animal heat will leave the carcass as quickly as possible. The following day they are graded into various classes according to weight and quality, packed usually 12 to a box, and stored in a freezing room at temperatures ranging from zero to below. This is the procedure which is generally followed in most of the poultry packing plants of today. As poultry is a seasonal product, it must be packed during the season of plenty and held under refrigeration to be marketed in the season of scarcity or at any time there is a favorable market for it.

Prior to 1928, little if any thought was given to the necessity of inspection of poultry. All poultry, whether fresh dressed, frozen, or prepared into canned products, was marketed and accepted by the consumer without inspection of any kind. About that time the New York City health authorities placed a regulation in their sanitary code prohibiting the sale of eviscerated poultry in that city unless it had been previously inspected and identified as such by an authorized agency which would be acceptable to them. This regulation particularly affected the packers of canned poultry products in that city, and they at once began to investigate the possibilities of federal poultry inspection; but since the Meat Inspection Act did not include poultry, it was not possible for the Bureau of Animal Industry to offer poultry inspection. However, an Act of Congress gave authorization to the Bureau of Agricultural Economics of the U. S. Department of Agriculture to inspect all perishable farm products including inspection and certification of dressed poultry for condition and wholesomeness. This was the beginning of a much needed service which was acceptable to New York City authorities. Interested poultry canners quickly applied for this service which made it

possible for their products to bear the inspection legend of the U. S. Department of Agriculture, which reads as follows: "Inspected and Certified by Bureau of Agricultural Economics, U. S. Department of Agriculture." Since that time, other large cities have passed similar regulations prohibiting the sale of uninspected canned poultry products, the result of which is that practically all prominent packers of canned poultry in this country are preparing their products under federal supervision.

The packing of canned poultry products has developed into an industry of vast proportions and great quantities of poultry are processed yearly to produce a variety of products such as:

- Chicken soup
- Whole and half chicken in gelatine
- Egg noodle and chicken dinner
- Egg noodle and giblets dinner
- Chicken a la king
- Deviled chicken
- Creamed chicken
- Chicken hash
- Boned chicken
- Chicken a la Creole
- Potted chicken
- Chicken stew with vegetables
- Chicken breasts with sauce
- Chicken tamales in sauce
- Chicken liver paté
- Salad chicken
- Chicken pot pie
- Chicken giblets
- Chicken liver spread
- Chicken liver soup for babies
- Sliced turkey with gravy

As I have previously pointed out that practically all prominent packers of canned poultry and poultry products utilize the poultry inspection service of the Bureau of Agricultural Economics, I shall attempt to describe the general procedure which is followed in the preparation of poultry for processing in a government inspected poultry canning plant.

The first requirement of government inspection is that the plant shall be of a construction that will meet satisfactorily all sanitary requirements of the

regulations. This means walls, floors, etc., constructed of impervious materials which can be easily kept clean by washing; properly trapped sewerage drains; ample natural light; sufficient artificial light for early morning or late evening operations; screened windows; proper ventilation; clean dressing rooms, and sanitary lavatories and toilets for all employees.

The equipment used for the inspection and evisceration of poultry consists of two electric motor-driven conveyor tables, one for inspection and the other for evisceration. These tables are similar to those used in the large packing-houses for small animals. They are a series of stainless steel or monel metal pans attached to a chain conveyor revolving over and under the table, and on each revolution on the underside of the table pass through a washing and sterilizing chamber.

After all pin feathers have been removed from the skin and the hair singed from the carcass, the birds are individually placed in the pans of the inspection table, and as they are carried along the line, plant employees open the abdominal and thoracic cavities to permit the federal licensed veterinary inspector to make inspection of all internal organs. Birds showing lesions of disease or otherwise unfit for consumption are condemned at this time. Fit and healthy birds are now ready for complete evisceration.

On leaving the inspection table, the head and feet are removed and the body of the carcass passed to the eviscerating table (which is similar to the inspection table except that it has stationary dressing units on each side, equipped with sprays of continuous running water). Here all entrails are removed, after which each carcass is conveyed to the end of the table to be immediately and thoroughly washed. These birds are now ready for further processing.

The duties of a veterinary dressed poultry inspector are not only to make post-mortem inspection of each and every bird, but also to see that the entire plant is kept in a sanitary condition at all times, that all processing is carried on under sanitary methods, that all ingredients other than poultry which have been included in approved formulae are of fit quality and of proper proportions, and that the finished product is labelled with only such labels as have been officially approved.

While large quantities of poultry are prepared and processed in canning establishments (and I want to commend the management of this great industry for the methods employed and the quality of poultry used in the producing of a convenient, nourishing, healthful, and palatable product), yet far greater quantities of poultry are prepared and consumed in hotels, restaurants, all kinds of eating places, and particularly in our homes. There are few of us who do not enjoy the meal at which poultry is served, whether it be broiled, fried, fricassee, or roast chicken, or a well browned stuffed turkey, goose, or duck.

Recognizing the fact that almost every home is a potential customer for their product, the dressed poultry packers are now preparing poultry for home consumption in a ready-to-cook fashion and there appears to be a steady and continued demand on the part of the consumer to purchase poultry which has been government inspected, fully eviscerated, washed, dried, and cellophane-wrapped and packaged under strict sanitary regulations. There is little doubt that in the not far distant future a great portion of the poultry produced in this country will be packed and marketed as a ready-to-cook product, and why not?

As I have stated previously, poultry is a seasonal product and, therefore, must be stored under refrigeration from

the season of plenty to the season of scarcity. There is, however, no good reason for holding in a refrigerating plant poultry that has not been previously eviscerated, the same as all other meat food products. The cost of storage and transportation is computed on a weight basis and, therefore, this service would be more economical and would lessen very much the possibilities of contamination and flavor of the product.

The consumer must necessarily become acquainted with the advantages of purchasing fully eviscerated and government inspected, ready-to-cook poultry. There can be no question as to its relation to health. In preparing this specially packaged poultry, only birds of top quality are used. They must be entirely free of pin feathers, they must be soft meated, and well fleshed, and some packers use only birds that will meet the specifications of U. S. Grade A.

The inspection of this poultry is conducted in the same manner as that of poultry for canning purposes. After inspection and complete evisceration and thorough washing by hand, each bird is then dried with paper towels and wrapped in cellophane. The actual net weight of the carcass is plainly marked on the package. All of these operations are conducted under rigid sanitary conditions, and the cellophane wrapping and sealing of the package protect the product from further contamination by handling.

It is necessary that this type of poultry be quickly and thoroughly frozen and kept in that condition until it reaches the consumer. Various types of quick-freezing methods are used and temperatures usually range anywhere from 10° to 50° below zero. In the past there has been some consumer prejudice to frozen foods and especially to poultry, but when one considers that all poultry which is packed in abundance

has been frozen prior to being marketed, it is our opinion that the evisceration and inspection of poultry at the time of slaughter would be a distinct advantage to the industry as well as to the well-being and convenience of the consumer because it is packaged in various types of cellophane sanitary wrapping, and some classes of poultry such as broiling and frying chicken and fricassee fowl are dismembered in proper portions for serving at the table.

If the marketing of this type of poultry is to become successful, the purchaser must expect and accept its delivery to him in a hard frozen condition. The defrosting process is easily and quickly accomplished in the home.

Now in comparison, if the consumer is to continue to accept for home consumption defrosted uninspected poultry, the usual procedure of marketing this type of poultry is as follows. The retail merchant receives the greater portion of his poultry in a frozen condition and it is a common practice of the retailer to defrost the poultry entirely, as it then presents a more normal appearance and is more easily drawn. It is possible that in many instances birds are kept in a defrosted condition for several days before they reach the actual consumer. While being held in this condition, chemical action and decomposition take place, and the gases which form from the intestinal contents and food in the crop and gizzard permeate the flesh. This results in a strong flavor in the poultry, and there is also the possibility of the presence of disease as well.

Poultry consumed in the home is as a rule eviscerated by the butcher, who is not educated to detect the lesions of disease, and therefore could not very well pass on its fitness for food, as far as disease is concerned. In many instances, the work of evisceration of poultry in the retail market is done on the same cutting-board or chopping-

block where other meats are cut. There are usually considerable intestinal excreta and other fluids from the carcass smeared over the cutting-board, and if this filth is not immediately and thoroughly cleaned off, the next steak which is sliced off a loin of beef is likely to become contaminated to some extent. This practice indicates the desirability of poultry being delivered to the market fully eviscerated, after have been inspected, the same as other meat products. There are, of course, sanitary meat markets where a special work-bench is provided for the handling of poultry.

As a matter of information concerning the quantity of poultry now being government inspected in the United States, there have been inspected during the period of a year 43,550,124 lbs., of which more than 743,777 lbs. were

condemned as unfit for food. The causes for condemnation were various, such as avian tuberculosis, septicemia, emaciation, decomposition, peritonitis, tumors, leukemia, abscesses, and other conditions, but avian tuberculosis by far exceeds all other causes for rejection of poultry as unfit for food. Poultry which has been condemned by the inspector as not fit for food purposes is denatured usually with crude carbolic acid or denaturing oil, or in many instances incinerated.

In conclusion, it would seem of great importance that the housewife particularly, who is greatly interested in promoting the health and well-being of her family, should insist, when making purchases of either canned poultry products or full eviscerated poultry, that it show identification of having been government inspected.

Typhoid Fever and Vegetable Juices (Carrot)

J. C. GEIGER, M.D., F.A.P.H.A.

*City and County Director of Public Health,
San Francisco, Calif.*

THE importance of adequate supervision and control of food manufacturing and dispensing establishments was demonstrated in a recent investigation by the San Francisco Department of Public Health.

A case of typhoid fever was reported. The important facts are: V. T., age 40, a secretary, became ill. Clinical symptoms suggested typhoid fever, which diagnosis was confirmed in the laboratory. There was no evidence pointing to a source of infection outside of the city of San Francisco. The patient ate at home or at the homes of friends or relatives except for lunches, which were eaten at 4 food shops, but most frequently at one, a food store specializing in the sale of vegetable juices.

A second case of typhoid fever was T. N., age 22, a clerk in a large department store. The onset of symptoms was approximately on the same date as in V. T. Blood and stool cultures were positive for *E. typhosus*. This patient had limited his activities to the city of San Francisco, except for Sunday automobile trips to the country, on which food and water were carried from home. All meals were consumed at home, except lunch, which was taken at the same food store most often patronized by V. T.

DISCUSSION

The usual routine investigation of food handlers and the examination of food products that might have been a source of infection were carried out. Investigation including stool examinations of all known family contacts as well as the food handlers in the restaurants and the food store involved, was made.

The vegetable juices sold by the food store showed a high bacterial count. It was found that pasteurization of these juices had been incompletely carried out, or omitted, in violation of the regulations of the Department of Public Health, effective November 3, 1936.

The worker recently assigned to the direct preparation and handling of the vegetable juices was found to be a typhoid carrier. Stool specimens were positive for *E. typhosa* on 3 successive examinations. All other laboratory examinations were negative.

The typhoid carrier, C. K., age 40, had worked as a domestic in several families and gave a history of having had typhoid fever 34 years previously. She admitted that the vegetable juices had generally not been pasteurized.

LABORATORY STUDIES

A short series of studies in the labo-

ratory made clear the more essential points. A prolonged study is necessary, however, to provide a complete background for control work.

Freshly prepared carrot juice is a slightly acid product, pH 6.5 to 6.7. The bacterial content of fresh juice varies between wide limits, coming from the surface of the carrot and from the steps in processing. A perfect cleansing operation, in the surgical sense, followed by aseptic technic, should result in virtual sterility. Using elaborate precautions, however, a minimum count of 2,800 colonies per cc. was secured. The maximum count was 3,000,000 colonies per cc.

No standards exist with regard to bacterial colony counts as an index of sanitation, and it is questionable whether any satisfactory standard of this sort should or could be practically established. The results when elaborately careful laboratory preparations of juice were tested suggest strongly that the fluctuations in counts in juice from any given establishment would be so wide that differentiation between sanitary and unsanitary preparation on the basis of a colony count would not be proper. Emphasis must be placed on sanitary premises, on thorough cleansing operations at all points, and on personnel.

Pasteurization follows principles which have been firmly established. In no sense does pasteurization sterilize the juice which may, therefore, be expected to spoil. Both raw and pasteurized juices are excellent culture media for bacteria. The heating process, however, by reducing the number of living organisms and injuring others, induces a definite lag in spoilage. This lag may be real and may be helpful, but it should not be emphasized; juice still may spoil so rapidly that it is necessary to guard against a false sense of security. Spoilage is ordinarily indicated by decomposition, leaving a

product wholly unpalatable. This is accompanied by some acidification (pH 4.5 or higher, depending on the juice and the conditions of holding). The acidity of fresh juice is not significantly altered by pasteurization. Pasteurization reduced the colony count materially in all cases but, due to the different flora and to minor variations in the heating process, much irregularity was observed. Reductions in count to 1/50 or 1/100 of the count on raw juice were usual.

The chief value of pasteurization is that it destroys pathogenic organisms and that it does this during the last stage of preparation. Experiments showed that coliform organisms were usually eliminated and always sharply reduced. Freshly isolated *E. typhosa*, liberally inoculated, in no case survived. The typhoid bacillus did not die in raw juice; *i.e.*, the juice itself does not kill this organism. Extended investigation would be needed to demonstrate conclusively that 140° F. for 30 minutes is not adequate and that 142° F. or 143° F. for 30 minutes would be preferable as a lower limit. This conclusion was suggested from the data secured, however, particularly if rapid cooling following pasteurization is practised.

Chlorination as such was not found to be satisfactory. Even with carefully scrubbed hands, with carrots immersed in chlorine, 200 p.p.m., and with the use of completely sterilized apparatus, the bacterial count was appreciable and spoilage was not greatly delayed. Chlorination is, of necessity, introduced at an early stage in a processing in which the later stages introduce the greater risk. The practical proof of the value of chlorine rinse of the washed carrot followed by extraction and pasteurization of the juice would be difficult due to the lack of suitable criteria for the measurement of the potential degree of effectiveness. The

action of chlorine, however, might be worth considering if standards are to be established, not as adequate by itself but as an additional step in the preparation of good juice for pasteurization. The bacteria are ground in and a casual washing process will not be offset by chlorine treatment. Examination of a carefully scraped carrot, rinsed in clean water, would inevitably show that more bacteria had been *removed*. Further investigation might show that, between improved cleansing and chlorine, the former would be preferable; but that, between the best practical cleansing operation without chlorine and with chlorine, the use of chemical aid might be worth while. No laboratory evi-

dence has thus far been adduced to favor the use of chlorine at any stage.

COMMENT

The pertinent facts given above illustrate the necessity for very close, frequent, and careful supervision by health authorities over food establishments preparing and serving foods of any character, but particularly, as in this instance, unheated, or partially heated, extracts and juices from vegetables.

Specific orders of the Department of Public Health as to the pasteurization of such juices were apparently ignored or forgotten, with two cases of typhoid fever as a result.

Medical and Nursing Service

I WISH to voice a resentment to the implication that men and women in public service are any less worthy in education, in capacity, in attention, in interest, in devotion to duty, than those who are in what we call "private life." I resent the imputation that a salary stultifies, that we must receive a fee for every service rendered or else perform it grudgingly or inefficiently or both. This is no more true of the medical and the nursing professions than

it is of those who are by established custom paid for their services in this way. Granted a satisfactory standard of living, the remaining satisfactions are not those derived from monetary income, but from an appreciation of work well done.—Edward S. Godfrey, Jr., M.D., State Commissioner of Health, in address before the 1939 Annual Conference of Health Officers and Public Health Nurses, Saratoga, N. Y.

Outbreak of Staphylococcus Milk Poisoning in Pasteurized Milk

JOHN F. HACKLER, M.D.

Director, Payne County Health Unit, Stillwater, Okla.

A NUMBER of epidemics of staphylococcus toxemia from milk and related foods have been reported.¹⁻⁴ Some strains of *Staphylococcus aureus* secrete soluble exotoxins which give rise to acute attacks of diarrhea. A number of epidemics from this cause have been reported. The organism grows best in foods containing considerable carbohydrate. Cake, custard, eclairs, and milk contaminated by an abscess in a cow's udder have been incriminated.^{5, 6} This report is made not because the condition is new or rare, but because the method of contamination is of particular interest, and because the milk, being pasteurized, was supposedly safe.

On Saturday morning of September 25, 1937, the Oklahoma Agricultural and Mechanical College Infirmary admitted 9 students between 10 o'clock and noon, having the usual symptoms of an acute gastro-intestinal intoxication, with varying degrees of severity — nausea, vomiting (some bloody), cramping, and diarrhea. These 9 persons ate their breakfast at three different places. A hasty check with private physicians of Stillwater revealed 3 cases at one other address—a total of 12 cases within 2 hours' time.

Again shortly after the noon meal, between 1 and 3 o'clock, 5 more cases were admitted to the college infirmary, all from one fraternity house, and 3

cases were reported by a private physician—a total of 8 cases from three houses within 3 hours after lunch.

No more cases were reported until Monday, September 27, (2 days later) when 4 more cases were admitted to the college infirmary and 5 more cases were reported by private physicians. This made a total of 9 cases for the day, from 4 different houses. These cases resembled very closely those of 2 days earlier.

Epidemiological investigation of all cases revealed one fact—all 29 had drunk varying amounts of milk produced by one local pasteurizing plant. Some had drunk milk, some used it on cereals, and one mild case used it only in hot chocolate. Other members of these families and boarding houses who ate at the same table but who did not use milk suffered no ill-effects whatever. In one case the husband used no milk for breakfast but drank milk for lunch from the same bottle from which his wife drank in the morning. He likewise became quite ill within 2 or 3 hours after lunch, as had his wife after breakfast.

The onset in most of the cases was approximately 3 hours after drinking the milk, but varied from 1½ to 7 hours. Other foods tested from places where several persons were ill revealed no toxic bacteria.

Remaining portions of milk were collected from the various places where

cases occurred and samples from the same bottles as those causing illness were tested and found to contain "potentially toxic staphylococci; no hemolysis; active zoning."

All milk causing illness is thought to have been pasteurized on Friday, September 24, 1937. Of the 9 cases occurring on the 27th, 5 are known to have drunk milk purchased from a fruit stand on Sunday afternoon, September 26, and left there the day before. The remaining 4 cases had delayed opening their milk over the week-end for various reasons.

Records of all pasteurizations from September 23 to 29 were examined. These showed that the pasteurization had been carried out properly. The phosphatase test revealed adequate pasteurization of all samples tested, including some of those which actually caused illness and from which staphylococci were cultured. These facts led us to believe that contamination occurred after pasteurization, for that process would have killed the organisms even though it might not have destroyed the soluble toxins.

Inspection of the pasteurizing plant revealed that equipment was in good condition but that it was not at all adequate in so far as safe and clean milk production is concerned. Cleaning and sterilizing equipment were found inadequate and bottling and capping were being done by hand.

Five employees of the plant were examined and 3 of these were found to have positive nose or throat cultures for "potentially toxic staphylococci." One of these persons had pustules on his face and body.

Cultures on raw milk samples from 6 producers for the plant revealed "potentially toxic staphylococci" in 4 of the 6 supplies; therefore work needs to be done on herds of producers as well as in the plant.^{1, 7}

The actual method of contamination

of the pasteurized milk must of course be more or less a matter of supposition, but it seems quite likely that it occurred in bottling and capping, either by contamination from hands, or by sneezing or coughing across a group of bottles.

SUMMARY AND CONCLUSIONS

1. The week-end outbreak consisted of a total of 29 cases from 11 different residences. All but 3 or 4 of the cases were able to leave the infirmary or care of their physicians the following day. These 3 or 4 remained in the hospital from 2 to 4 days, the reason being the extreme weakness following severe nausea, cramping, bloody vomiting, and bloody diarrhea.

2. "Potentially toxic staphylococci" were isolated from samples of milk causing illness and upon which the phosphatase test revealed adequate pasteurization; therefore contamination occurred after pasteurization.

3. "Potentially toxic staphylococci" were isolated from the nose or throat of 3 of the 5 employees of the plant, one of whom had numerous pustules on his face and body.

4. Contamination presumably occurred during the process of bottling and capping, which were done by hand.

5. Equipment at the plant, though in good condition was quite inadequate.

6. The plant in question sold its milk as "Grade A Milk," yet was not violating any of the provisions of the city ordinance in effect at that time. The U. S. Public Health Service Standard Milk Ordinance adopted a short time previously and to be put into effect the following January 1, 1938, contains provisions which make the combination of circumstances responsible for this outbreak quite improbable.

NOTE: I wish to express my appreciation to all those who rendered valuable assistance in stopping this outbreak, reporting cases, and locating the source. In particular I should like to mention among these Dr. W. C. Thompson, Director of the Student Health Service of the Oklahoma A. & M. College; Dr. M. R. Beyer, Epidemiologist, and W. J. Wyatt, Milk Specialist, of the Oklahoma Health Department; C. R. Millard, Sanitarian of the Payne County Health Unit; C. P. Peck, City Milk Inspector of Stillwater, Oklahoma, and the Laboratory of the Oklahoma Health Department.

Health Department Personnel

THE funds for the courses given to our new personnel have all come from the federal government and it is proper that this should be the source. We have no assurance that the person so trained and educated will remain in the employment of New York State or one of its component municipalities. I am opposed to stipulating any such obligation on the part of the recipients or of the state. Not only is there some doubt in my mind as to the legality of such a stipulation, but it seems a most unwise requirement. To hold a person to a job against his will, against his best interests, can only lead to discontent and a disturbance of morale which may be more costly than the expense of education and training. He should be

free and not a bondsman. On the other hand, this state and its municipalities should be free to seek personnel wherever the best qualified can be found, whether in this state or another, whether trained under our allotment or that made to another state. Parochialism has no more place in the government service, especially the public health service, than it has in commerce and industry. If the public really wants a comparable efficiency, it must grant government a comparable freedom in the selection of those who are to serve it.—Edward S. Godfrey, Jr., M.D., State Commissioner of Health, in address before the 1939 Annual Conference of Health Officers and Public Health Nurses, Saratoga, N. Y.

A Comparison of MacConkey's Broth and Standard Lactose Broth as Media for Detection of Coliform Organisms in Water

M. H. McCRADY, F.A.P.H.A.

*Chief of Laboratories, Quebec Ministry of Health,
Montreal, Que., Canada*

SINCE the first year of the 20th century the name of Alfred MacConkey has been closely linked with the development, in England and many other parts of the British Empire, of bacteriological methods of water analysis. It was in 1901 that MacConkey and Hill, following earlier research by the former on the use of bile salts for the differentiation of certain groups of bacteria, published a paper entitled, "Bile Salt Broth. A Simple Test for Faecal Contamination."¹ Their suggestion of the use of bile salts in sugar broth for facilitating the search for coliform organisms in water met with immediate favor, and was soon adopted by the great majority of British bacteriologists. To this day bile salts have remained in British practice an indispensable ingredient of the primary medium employed for detection of the presence of coliform organisms in water, sewage, milk, and a variety of other materials.

The original formula of MacConkey broth, however, is not exactly that which is in use today. The earlier bacteriologists, recognizing the fact that many enteric disease organisms

ferment glucose but not lactose, quite naturally concluded that the fermentation of glucose offered the best primary indication of the presence in a water of organisms associated with dangerous pollution. The same predilection for glucose in enrichment media is evident in the formulae for glucose broth employed at that time by American bacteriologists, but before long it was realized that the glucose fermenting group includes a vast number of organisms which do not compare with the lactose fermenters as pollution indicators, and gradually the glucose of MacConkey broth was displaced by lactose. Similarly, on this side of the Atlantic, the glucose broth employed as primary medium was superseded by lactose bile.

This substitution of lactose for glucose constitutes the only important modification that the original MacConkey broth formula has suffered. It is interesting to compare, for example, this original formula with that used today by the Metropolitan Water Board of London.

One other, but minor modification has been rather generally accepted. Following the suggestion of Savage,²

Original MacConkey

Sodium taurocholate	5 gm.
Glucose	5 "
Peptone	10 "
Water	1,000 cc.
Litmus	to give distinct color

Metropolitan Water Board

Sodium taurocholate	5 gm.
Lactose	10 "
Peptone	20 "
Water	900 cc.
Litmus	100 cc. 0.5% solution

neutral red is often substituted for the litmus of the formula, not only because neutral red is a more satisfactory indicator of acid fermentation but also because many coliform organisms produce, in a glucose or lactose medium containing it, a fluorescence that furnishes additional evidence of their presence. The formula recommended in the revised edition (1939) of *Report No. 71*, published by the Ministry of Health,³ which constitutes, for all practical purposes, the British equivalent of the bacteriological section of *Standard Methods of Water Analysis*,⁴ includes this usual modification.

MacConkey broth is employed in fermentation-tubes as a primary enrichment broth, just as is standard lactose broth in the United States and Canada. It must be noted, however, that, unlike standard lactose broth, the ingredients of which are so chosen as to favor the multiplication of the greatest possible number of varieties of coliform organisms, MacConkey's broth, because of its bile salt content, is rather a *selective* medium: the purpose of the bile salt is to inhibit non-coliform organisms, and to favor the multiplication of the so-called fecal type of coliforms (indol positive, methyl red positive, Voges-Proskauer negative, citrate negative). Because of this selectivity, it appears that the multiplication of some coliform types may likewise be inhibited, particularly that of certain

slow lactose fermenting aerogenes organisms.

Nevertheless, partly because coliform organisms of the "fecal" type constitute a large proportion of the coliform flora of Britain's waters compared with that encountered in the waters of some other countries, and partly because English bacteriologists have consequently stressed the importance of a search for the more typical *Escherichia coli* of the coliform group, MacConkey broth has easily held its place in British laboratory practice. Apparently, in Britain, gas in MacConkey broth nearly always indicates the presence of coliforms; *Report No. 71* of the Ministry of Health³ contains, for example, this statement:

It is true that the bile salt has a slight inhibitory effect on the growth of the coliform organisms themselves, but this disadvantage is more than outweighed by the practically complete elimination of false positive reactions. With very few exceptions it may be taken that the production of acid and gas in MacConkey medium inoculated with water indicates the presence of coliform bacilli. Since the conclusive proof of this can be brought only by further tests, a reaction of this sort is generally referred to as a "presumptive positive coliform reaction." The presumption is, *in this country*, however, very high. In other countries, where the water flora is different, false positive reactions in this medium may not infrequently be encountered.

MacConkey broth has never been very generally employed in America. Although the principle of the use of bile ingredients in media has often been proposed here, whole bile (oxgall) instead of bile salt has usually been specified. The chief reason for this preference for whole bile has been an uncertainty regarding the composition of the commercially available "bile salt." There exist, apparently, no generally accepted specifications for the manufacture of this ingredient. English directions for the preparation of MacConkey broth usually designate a par-

ticular supply house or supply houses as the source of the bile salt to be used. Since no control is exercised to insure uniformity of composition of the bile salt sold by different firms, variation in the characteristics of media prepared with different brands of bile salt is to be expected. Even some 15 years ago Sir Alexander Houston, in his *Nineteenth Annual Report to the Metropolitan Water Board* (1925), voiced this complaint:

In pre-war days there were two simple tests of real value: (a) the number of bacteria growing at 37° C. in an agar lactose bile-salt medium, and (b) the gaseous fermentation at 37° C. of liquid lactose bile-salt cultures. The chief reason why these two tests were of such value was the selective character (in favour of *B. coli*) of the bile-salt (introduced by MacConkey). Since the war all the samples of bile-salt that have been tried in the Metropolitan Water Board Laboratories have proved most disappointing in this selective sense, and this, the writer thinks, is common experience. In the old days the presumptive evidence afforded by, at all events, test (b) was so valuable that confirmatory tests seemed almost unnecessary. Now test (a) is almost valueless and implicit reliance cannot be placed on test (b).

Similar complaints have been expressed by other English laboratory workers; and the author has noted marked variations in the characteristics of media prepared with the "bile-salts" furnished by different American firms.

At present, the bile salt usually employed in Britain is designated as "Commercial Sodium Taurocholate" which is supplied by commercial chemists under the name of "sodium tauroglyco-cholate."⁵ The Metropolitan Water Board Laboratories, however, purchase Merck's brand, sufficient material of any one particular batch being prepared by the manufacturer to suffice for a year in order to obtain standard results over that period.⁶

It is obvious that the lack of more or less rigid specifications for the production of the bile salt to be used in

MacConkey's medium constitutes an unsatisfactory situation. British laboratory workers are fully aware of this fact, however, and it is probable that before long they will adopt specifications to insure uniformity of composition of this important ingredient.

EXPERIMENTAL

Occasional inquiries, by American water bacteriologists, regarding the comparative utility of MacConkey broth and standard lactose broth for examination of waters on this continent have led the Committee on Standard Methods to undertake a study of these media. The following four laboratories, two engaged in the control of city purification plants and two state or provincial laboratories, exercising control of waters from a variety of sources, agreed to collaborate in the work.

City of New York—Mt. Prospect Laboratories
F. E. Hale and H. F. Muer

City of Toronto—Centre Island Laboratories
N. J. Howard and R. E. Thompson

State of Maryland—Dept. of Health Laboratories

C. A. Perry and A. A. Hajna

Province of Quebec—Ministry of Health Laboratories

M. H. McCrady and J. Archambault

The New York City samples consisted of raw and treated surface waters; those of Toronto were largely raw, slow sand filtered and drifting sand filtered waters together with a few chlorinated (finished) waters; the Maryland samples included various raw, coagulated, filtered and finished surface waters; whereas the Quebec samples were from springs, wells, lakes, streams and filtration plants, with well (surface and deep) and spring samples predominating.

The routine procedure adopted for this study was as follows:

1. Plant 5 portions of 10 cc. each and 5 portions of 1 cc. each of the sample in standard lactose broth and similar amounts in MacConkey broth.

2. Incubate at 37° C. for 48 hrs.

3. As soon as gas appears in any tube, confirm completely according to *Standard Methods of Water Analysis* (EMB plate, secondary lactose, agar slant, Gram-stained preparations, etc.)

4. As soon as gas appears in a lactose broth tube, in addition to the complete confirmation specified in (3), transfer 1 loopful of the culture to brilliant green bile; incubate the latter at 37° C. for 48 hrs.; and as soon as gas appears in the tube, confirm completely as in (3) above.

These procedures permit comparison of 5 methods of examination:

a. Standard Method with complete confirmation via lactose broth

b. Standard Method with complete confirmation via brilliant green bile

c. Standard Method with confirmation (production of gas only) by brilliant green bile

d. MacConkey broth presumptive test (production of gas only)

e. MacConkey broth method with complete confirmation

The brilliant green bile procedure was included because of the widespread interest in the favorable results secured by this means of confirmation in the course of a previous coöperative study.⁷

The brilliant green bile (2 per cent) and eosin-methylene-blue (both in dehydrated form), the lactose, peptone, and neutral red employed were furnished through the courtesy of Difco Laboratories, Detroit, Mich. "Sodium Taurocholate" was purchased from Baird and Tatlock, London, England (one of the firms suggested as furnishers of this ingredient by Dr. W. M. Scott, of the Ministry of Health, who also informed the author that "Bacto" products such as peptone, agar, lactose, and neutral red would be regarded there as suitable for the preparation of the media listed in *Report No. 71*).

The MacConkey broth used was made according to the formula and directions of *Report No. 71*, given below; double strength broth, in 10 cc. quantities, was employed for the inoculation of 10 cc. portions of sample,

single strength broth for smaller portions.

Commercial sodium taurocholate	5 gm.
Lactose	10 "
Peptone	20 "
Sodium chloride	5 "
Distilled water	1,000 ml.

Directions for preparation: "Steam for 2 hours and transfer to the ice-chest overnight. Filter in the morning through Chardin paper while still cold. Adjust the reaction to pH 7.4, using phenol red as the indicator. Add about 10 ml. of 1 per cent aqueous solution of neutral red and sterilize in the autoclave at 10 lb. for 15 minutes, or in the steamer for 30 minutes on 3 successive days. The finished medium should be clear and should have a claret red color, free from yellow or magenta."

The use of eosin-methylene-blue agar, instead of MacConkey agar, for plating-out from fermentation tubes, constituted a departure from British practice, but since there seemed to be no reason for believing that E.M.B. agar was inferior to the other, and since most workers here are much more familiar with the former than with the latter medium, the departure appeared to be justified.

It may be noted, in this connection, that Atkinson and Wood,⁸ working with Australian waters, succeeded in completely confirming 296 of 614 presumptives with the aid of E.M.B. agar, and only 277 by using MacConkey agar, despite an unusual practice of fishing mixed growths on MacConkey agar to fermentation tubes and again plating on MacConkey agar. It must be admitted, however, that absolutely identical results may not be secured from the use of MacConkey agar and that of E.M.B. agar.

RESULTS

The results obtained by means of the 5 different methods employed are shown in Table I.

It will be observed that, in the aggregate, the number of coliform isolations was about the same whether Mac-

TABLE I

No. of Samples Producing Gas in One or Both Primary Media		MacConkey Broth Primary Tubes			Lactose Broth Primary Tubes			
		Presump- tives Gas +	Coliform Isolations		Presump- tives Gas +	Coliform Isolations	Br. Green Confirmation	
			No.	Per cent			Gas	Coliform Isolations
New York City	96	217	131	60	367	132 (12)	141	115 (6)
Toronto	30	134	82	61	137	92 (8)	127	98 (2)
Maryland	22	94	92	98	124	92 (1)	87	86 (1)
Quebec	73	406	326	80	442	327 (34)	359	335 (8)
		851	631	74	1,070	643 (55)	714	634 (17)

* Figures in parentheses indicate the number of tubes showing gas from which no coliforms were isolated, but from the corresponding lactose broth primary of which, coliforms were isolated by the other method. Thus, the indication (6), at the end of the first line of the table, signifies that 6 of the 141 gas positive brilliant green confirmatory tubes failed to yield coliform upon attempted isolation, but coliforms were isolated directly from the corresponding 6 lactose broth primary tubes.

Conkey broth, lactose broth, or lactose broth followed by secondary brilliant green bile was employed. Toronto's coliform isolations by means of these 3 media, however, numbered 82, 92, and 98 respectively, the use of MacConkey broth resulting in a loss of 16 per cent of the number of coliform isolations secured through the use of lactose broth followed by transfer of gas positives to brilliant green bile. Quebec's results are somewhat similar, although here the loss due to the use of MacConkey broth was only about 3 per cent. New York and Maryland, on the other hand, isolated the same number of coliforms from MacConkey broth and lactose broth, the use of brilliant green bile secondary resulting in a loss of 11 per cent and 7 per cent, respectively, of the isolations obtained directly from the other two media.

A comparison of the number of MacConkey presumptives with the number of coliforms isolated from them shows very clearly that in at least 3 of the 4 laboratories gas in MacConkey broth cannot be relied upon as an indication of the presence of coliform organisms detectable by the routine complete confirmation procedure; for from a total of 851 MacConkey presumptives only 631, or 74 per cent, were shown to

contain coliforms. Apparently the coliform flora of the waters examined by 3 of the laboratories differs considerably from that of British waters.

On the other hand, although, as already indicated, about as many coliform isolations were secured from the MacConkey presumptives as from the lactose broth presumptives, the former numbered only 851 whereas there were 1,070 of the latter. In other words, 219, or nearly 20 per cent, fewer presumptives had to be confirmed when MacConkey broth was employed.

It is interesting to compare this experience with that encountered in an earlier study⁷ of the relative utility of fuchsin broth and lactose broth primary media. The data requisite for such a comparison are shown in Table II. The results obtained from the use of confirmatory brilliant green bile are included.

Section A of Table II shows the results of examination of 890 water samples (1936-1937 series) by means of 3 procedures: fuchsin broth primary with complete confirmation; lactose broth primary with complete confirmation; and lactose broth primary followed by brilliant green bile secondary, with complete confirmation of the latter. In Section B are

TABLE II

A. Results from Examination of 890 Water Samples (1936-1937 Series)

		Presumptives		Coliform Isolations		
		No.	Per cent of LBP Presumptives	No.	Per cent of Positive Presumptives	Per cent of LBP + SMC Isolations
Fuchsin Broth	(+ SMC)	2,903	69.1	2,048	70.5	97.06
LBP	(+ SMC)	4,204	100.0	2,110	50.2	100.00
LBP + BG	(+ SMC)	2,384	56.7	2,079	87.2	98.53

B. Results from Examination of 221 Water Samples (1938-1939 Series)

MacConkey Broth	(+ SMC)	851	79.5	631	74.1	98.13
LBP	(+ SMC)	1,070	100.0	643	60.1	100.00
LBP + BG	(+ SMC)	714	66.7	634	88.8	98.60

SMC = Standard Methods Complete Confirmation Procedure (Agar plate, 2nd Lactose, Agar slant, Gram stain, etc.)

LBP = Lactose Broth Primary

BG = Brilliant Green Bile employed for confirmation of Lactose Broth Primary

given the results of examination of the present series of samples by using the same 3 procedures except that MacConkey broth has been substituted for fuchsin broth.

It will be observed that, when fuchsin broth was employed, the number of presumptives to be confirmed was only 69.1 per cent of the number of lactose broth presumptives, although the number of coliform isolations obtained from these fuchsin broth presumptives was 97.06 per cent of the number obtained from the lactose broth presumptives. The corresponding proportions, when MacConkey broth was employed in the later series of samples, were 79.5 and 98.13 per cent. Evidently greater economy of effort, with respect to the proportional number of presumptives to be confirmed, resulted from the use of fuchsin broth in the first series of examinations, than with MacConkey broth in the second series, despite the fact that coliform organisms were isolated with greater facility, at least from lactose broth presumptives, in the latter series (probably because of the larger proportion of typical coliforms, derived from raw and unfinished waters, contained in the second group of samples).

It will also be noticed that the percentages of fuchsin broth and MacConkey broth presumptives that yielded coliform isolations did not differ greatly (70.5 and 74.1), and that the ratios of recoveries from brilliant green bile secondary to those from lactose broth directly were almost identical for the two series (98.53 and 98.60 per cent).

It appears, therefore, that from the figures for the aggregate results secured from these 2 series of examinations, fuchsin broth yielded results practically as satisfactory as those obtained from the use of MacConkey broth. Both media, compared with lactose broth, were of some value in reducing the number of presumptives to be confirmed, although they permitted about as many coliform isolations as did the standard medium. Whether they would prove to be as satisfactory for the examination of finished waters is a question; because of the few coliform organisms contained in finished waters, only the results from a very large number of samples of such waters can determine definitely the effect of the inhibiting agents employed in these media. In any event, presumptives in either fuchsin or MacConkey broth must be confirmed, for when used for examination

TABLE III

Number of MacConkey Presumptives, Secondary Brilliant Green Bile Gas Positives and Coliform Isolations from Lactose Broth

	MacConkey Presumptives (Gas +)	Secondary Brilliant Green Bile (Gas +)	Coliform Isolations from Lactose Broth by Complete Confirmation of Lactose Broth or Brilliant Green Bile Gas Positives
New York	217	141	142
Toronto	134	127	100
Maryland	94	87	93
Quebec	406	359	361
	<hr/> 851	<hr/> 714	<hr/> 696

of American waters, they have not proved generally satisfactorily indications of the presence of coliform organisms.

On the other hand, it is evident from Table III that the presence of gas in brilliant green bile, following transfer from a lactose broth tube in which gas has been produced, indicates fairly accurately the presence of coliform organisms except in the Toronto laboratory where, of 127 brilliant green bile gas positive tubes, only 100 were shown (by confirmation directly from the primary lactose broth or indirectly from the brilliant green bile) to represent lactose broth primary tubes containing coliform organisms. It is probable, however, that a more intensive search would have shown the presence of gas in brilliant green bile to be a somewhat more reliable indication of the presence of coliforms in these Toronto waters than that furnished by these figures, for a varying proportion of coliform organisms usually escape the routine complete confirmation procedure.

The results secured from this comparison of MacConkey broth and lactose broth are somewhat similar to those reported by Atkinson and Wood⁸ in Australia. Working with untreated waters from various sources, they planted 5 portions of each of 3 dilutions of 34 different samples into the 2 media, confirming completely in accordance with American methods (ex-

cept in the use of MacConkey agar instead of E.M.B. or Endo agar) all tubes in which gas was produced. The results were as follows:

MacConkey Broth		Lactose Broth	
Presumptives	Con- firmed	Presumptives	Con- firmed
216	174	305	247

With both media, 81 per cent of the presumptives were successfully confirmed. But lactose broth yielded 42 per cent more coliforms than did MacConkey broth; and in 27 of the 34 samples examined, the coliform count resulting from the use of lactose broth was the greater of the two. The authors conclude: "Thus the British Standard Method using MacConkey broth without confirmation is not suitable for the examination of the type of water tested here, on account of the inclusion of false positives and the lack of sensitivity of the medium to the coliform group"; and they state that the method adopted for bacteriological analysis of Victorian drinking water is practically that given by the American Public Health Association (1933).

CONCLUSIONS

A limited study of the relative utility of MacConkey broth and lactose broth as primary media and of brilliant green bile as a confirmatory medium was undertaken by 4 different laboratories. The results may be summarized as follows:

1. The MacConkey presumptive (presence of gas within 48 hrs.) did not prove to be, in general, a satisfactory indication of the presence of coliform organisms. False presumptives (or at least presumptives from which such organisms were not isolated by means of the usual complete confirmation procedure) constituted 2, 20, 39, and 40 per cent of all MacConkey presumptives encountered by the Maryland, Quebec, Toronto, and New York laboratories respectively.

2. Complete confirmation of MacConkey presumptives yielded about as many coliform isolations as did like confirmation of the larger number of lactose broth presumptives, or of brilliant green bile confirmatory gas positives. The economy in number of presumptives to be confirmed obtained through the use of MacConkey broth, however, did not appear to surpass that which was secured in a previous study, through the use of fuchsin broth. The effect of the inhibiting agents employed in these two media upon coliform organisms that may be contained in finished waters has yet to be determined.

3. On the whole, the procedure employing lactose broth and confirmation (gas only) in secondary brilliant green bile appeared to yield more satisfactory results than the other procedures. In the Toronto laboratory, a

number of false positives were encountered in brilliant green bile as well as in MacConkey broth; but there also the procedure employing brilliant green bile, whether or not followed by complete confirmation, proved to be as satisfactory, or more satisfactory than that in which MacConkey broth was used.

OUR SIXTY-EIGHTH ANNUAL MEETING

THE 68th Annual Meeting of our Association was held in Pittsburgh, Pa., that center of industry which is one of the wonders of the world. It is the first time that we have ever met in that great city, and it has been 42 years since we have met in Pennsylvania. Having been in Pittsburgh once, we fear that we will not be satisfied anywhere else. Registration went well over 2,400.

We had some foreboding about attendance owing to the European war. This led to a number of cancellations especially from our constituent and sister country, Canada; but things have turned out better in regard to attendance from that country than we dared to hope since at least 19 representatives met with us.

Canada:

Robert D. Defries, M.D., D.P.H., Toronto, Ont.

Aime Cousineau, C.E., Montreal, Que.

Gordon J. Miller, D.D.S., Toronto, Ont.

Alexander L. McKay, M.B., D.P.H., Toronto, Ont.

Malcolm R. Bow, M.D., Edmonton, Alberta

Ethel Crydeman, Toronto, Ont.

Elise H. Hickey, Toronto, Ont.

John T. Marshall, Victoria, B. C.

R. G. Peat, Hamilton, Ont.

J. T. Phair, M.B., D.P.H., Toronto, Ont.

Elisabeth L. Smellie, R.N., Ottawa, Ont.

Harry S. Thomson, D.M.D., Toronto, Ont.

Alice Ahern, R.N., Ottawa, Ont.

M. S. Loughheed, Winnipeg, Man.

Ella Grant, Nurse, Toronto, Ont.

John J. Heagerty, M.D., D.P.H., Ottawa, Ont.

Gordon P. Jackson, M.B., D.P.H., Toronto, Ont.

Norman MacL. Harris, M.B., Ottawa, Ont.

Donald T. Fraser, M.B., D.P.H., Toronto, Ont.

From another constituent country, Mexico, two representatives:

Angel de la Garza Brito, M.D., C.P.H.

Alberto P. Leon, M.D., M.P.H.

From Cuba five honored us:

Dr. Gaspar Agramonte, Cuban Navy, Havana
Dr. Moises Chappotin, Cuban Army, Havana
Raoul Cowley, Marianao, Cuba
Dr. Alberto Ricio, Cuban Epidemiologist, Havana
Dr. Charles Finlay

We were happy to have Dr. Agramonte, a nephew of Dr. Aristides Agramonte who was on the famous commission with Walter Reed; also Dr. Charles Finlay, son of Dr. Carlos Finlay who made experiments in regard to yellow fever and who furnished Walter Reed the eggs from which he reared his mosquitoes and got his final proof.

We had a number of engagements from our honorary members in England, but all of these had to be cancelled. However, we were fortunate in having from Finland, a county health officer, Dr. Niilo Erkki Leppo, and his wife. From Puerto Rico, Dr. Oscar Costa-Mandry; Japan, Dr. Takemune Soda, Assistant Professor, Faculty of Medicine, Taihoku University, Formosa, Japan; Hawaii, Mr. Robert Lam, Honolulu Health Department, and Thomas O. Frazier, Honolulu Health Department; Alaska, Marcia S. Hays, M.D., Juneau; Virgin Islands, Dr. Norman R. Sloan. There were a number of most interesting trips for which transportation was furnished by the Local Committee.

The scientific exhibits were somewhat limited owing to the lack of space. Without being invidious, we want to mention that among the best exhibits were that from Kips Bay-Yorkville Health Center of New York City, most cleverly constructed, showing the value of a preventive diet, and the Pittsburgh Industrial Health exhibit. The commercial exhibit was excellent in every respect.

The scientific program was unusually rich, so much so that one could not but wish for at least a dozen bodies to attend as many meetings simultaneously.

Needless to say the principal features were the meetings on Tuesday and Thursday evenings. At the first on Tuesday, we were graciously welcomed by Mayor Cornelius D. Scully, the Health Officer, Dr. I. Hope Alexander, and the president of the local medical association as well as other local organizations. We will not comment on the president's address as that will appear in December. Among the features was the Delta Omega lecture which initiated a series which it is to be hoped will be continued, followed by the presentation of the Sedgwick Memorial Medal. This was followed by a reception to President and Mrs. Abel Wolman and to President-elect Dr. and Mrs. E. S. Godfrey, followed by dancing, altogether a most enjoyable occasion. The banquet on Thursday night was all that could be asked for. The presentation of forty year membership certificates to Dr. Norman McLeod Harris and Mr. John Watson Alvord was made, and the Health Conservation Contest awards were announced, followed by dancing on the Urban roof which again gave great pleasure.

As usual there were a number of advance meetings of related or affiliated organizations besides the Sixth Health Education Institute, all of which were well attended. Of special interest was the meeting of the Pennsylvania Public Health Association with the Tri-State Food and Health Officials. Following a joint banquet, a very large gathering was addressed by Dr. Henry F. Vaughan and the Honorable Fiorella H. LaGuardia, Mayor of New York City.

Too much cannot be said of the courtesies of the Local Committee. Everything was done for the comfort and entertainment of everyone. A special feature,

new in our experience, was the lovely flowers furnished by the Women's Entertainment Committee, under the chairmanship of Mrs. David B. Ludwig, for all occasions and changes of floral decorations for all public meetings.

DENTAL FLUOROSIS AND DENTAL CARIES

FOR some 8 or 9 years past the presence of fluorine in water supplies has been attracting much attention, chiefly as a danger and as the cause of endemic dental fluorosis, or mottled enamel, which has been reported in some 300 communities in 23 states of the Union.

According to Dean,¹ this condition was first described by J. M. Eager² in a report from Naples under the name "Denti di Chiaie (Chiaie teeth)," so called from Dr. Stephano Chiaie, who first observed the condition in Italy, where it was ascribed to volcanic fumes in the air or dissolved in drinking water. Italian immigrants not infrequently consulted doctors in this country for the condition, which was "unlike any other dental disease."

Apparently nothing was done until 1916, when Black and McKay^{3, 4} published a series of articles on the subject, Black describing it as "An Endemic Developmental Imperfection of the Teeth, Heretofore Unknown in the Literature of Dentistry." From that time until about 1932, the condition does not seem to have attracted much general attention. However, Black observed at that time some apparent relation between mottled enamel and dental caries. Other observations along this line were not abundant, but intensive work has been going on for 5 or 6 years, notably in the National Institute of Health and in some western states.⁵

The condition has been proved to be due to the use of water carrying toxic amounts of fluorides during the period of dental calcification. However, evidence has accumulated which indicates that a certain amount of fluorine in the water exercises some inhibitive action against caries, or, at least, that there is an inverse relationship between endemic dental fluorosis and dental caries. Many factors are involved but the careful plan followed in the study discussed here seems to have eliminated as many as possible of these.⁶

The four cities of Macomb, Quincy, Galesburg, and Monmouth, located near together in the flat country of North Central Illinois, were selected for comparison, and the examinations were limited to white children 12, 13, and 14 years old. The population in these four towns is very similar and they have approximately the same percentage of native white inhabitants—88–97. The location insures comparatively equal sunlight intensity.

In Galesburg and Monmouth the water supply contains from 1.7 to 1.8 parts per million of fluorides, whereas that of Quincy and Macomb has only 0.2 parts per million. Of 319 children in Galesburg and 148 in Monmouth, the number of carious permanent teeth per 100 children was 201 and 205 respectively, whereas of 112 children in Macomb and 306 in Quincy, the carious teeth were 401 and 633 respectively. There was twice as much dental caries in Macomb and more than three times as much in Quincy, where the water was practically free from fluorides, as at Galesburg or Monmouth. About 35 per cent of children examined in Galesburg and Monmouth were free from caries, while in Macomb and Quincy only 14 and 4 per cent respectively were free.

Another test was observation of interproximal, or smooth surface, caries for which the four superior anterior teeth of children who had used the city water supplies continuously throughout their lives were selected. In Galesburg and Monmouth, 2,718 surfaces examined showed an average of 0.59 carious lesions per 100 surfaces, whereas of 2,814 surfaces of children in Quincy and Macomb, there were 8.9 carious lesions per 100 surfaces, or 16 times as much.

An unusual feature of this investigation concerns the presence of *Lactobacillus acidophilus* which is believed by many to be a dependable index of the dental caries activity. Such examinations were made only at Quincy and Galesburg, where caries in permanent teeth amounted to 636 per 100 children in Quincy, 3.4 times the amount found in Galesburg, 189 per 100. The percentage of all acidophilus counts of 30,000 or over is also 3.4 times as high in Quincy as in Galesburg, possibly a coincidence, but an interesting finding in this general study.

This report, which does not pretend to be final, holds that from the epidemiological standpoint the difference in the water supplies must be considered the cause of the differences in the dental condition of the children examined. This points to the possibility of at least partial control of dental caries through the public water supplies. All studies of dental caries should be accompanied by complete chemical analyses of the domestic waters used, especially with regard to the comparatively rare elements.

THE TOXICITY OF SELENIUM

IN a recent article¹ attention was called to the problem of selenium poisoning, the danger from which seems to be increasing through the use of spraying, irrigation, and certain industrial practices. While we know little of selenium poisoning in human beings, the deleterious effects on livestock and poultry have been proved.

The question has been under study at the National Institute of Health for some time. Their latest report² is of great interest as showing the relation between the composition of the diet and the danger of poisoning. In all of their experiments a prominent characteristic of selenium poisoning has been in evidence; namely, the great variation in individual as well as in species susceptibility. Many experiments have been made in trying to find the cause of this. It now seems certain that as far as rats go the toxicity of selenium taken in food is largely determined by dietary factors. A quantity of selenium which proves highly toxic and damaging to the tissues when given in a diet low in protein and high in carbohydrate is only slightly or not at all harmful when fed in another diet high in protein and low in carbohydrate. In other words, all the available evidence indicates that the toxicity of naturally occurring food selenium is determined to a great extent not so much by the level of intake of selenium, as by the ratio between protein and selenium in the diet. While 10 parts per million of selenium, a ratio of 1 per cent protein in the diet to about 30 micrograms of

selenium per 100 grams of diet, is of very low, if any, toxicity, a ratio of 1 per cent protein to 100 micrograms selenium per 100 grams of diet under the same conditions is dangerously toxic. A diet low in protein and high in fat shows some protective action against selenium poisoning, probably due to the protein sparing action of the high fat content.

Is it possible that these findings may help to explain the lack of cases of poisoning from selenium in human beings?

BOOKS AND REPORTS

Fundamental Principles of Bacteriology with Laboratory Exercises—By A. J. Salle. New York: McGraw-Hill, 1939. 679 pp. Price, \$4.00.

The author states that this book has been designed for those beginning the study of bacteriology and particularly those who intend to specialize in it. It is a "textbook on fundamentals." It differs from others in that it is written as a combination textbook and laboratory manual, the experimental portion being woven into the manuscript under the proper chapters. "The textbook material goes hand in hand with systematically arranged laboratory procedures." The experimental material has been designed to meet the fundamental requirements of students not only in bacteriology but in "the various divisions of agriculture, forestry, home economics, sanitary engineering, physical education, hygiene, public health, etc.," and this is expected to be covered in a one semester course.

It can be seen from what the author says that his outlook is ambitious. To a large extent he has succeeded in his objective and has produced a useful book, especially as a reference. We fear that much of the material is heavy for an elementary course while in other respects it is not complete enough for the specialist. It is presupposed that the student will have a wide knowledge of inorganic and organic chemistry and there is much greater emphasis on chemistry than is found in other textbooks. While all knowledge is useful and one hesitates to criticise on this ground, it must be pointed out that the

book is crowded throughout with difficult chemical formulae, many in graphic form. It is a question of proportion. Under protein decomposition, 8 solid pages are given to chemical formulae, under classification of enzymes 13 pages, under biological strains 5 pages. There are 8 pages given to the preparation of stains and solutions and 10 pages to formulae and directions for making culture media.

The book is well written and clear. It can be recommended for reference but we doubt if it is well adapted for courses as usually given in any schools, medical, agricultural, or others, hence its adoption would necessarily lead to reorganization of instruction.

We like particularly the first two paragraphs of the Preface quoted from John R. Wilbur, which states what a preface should be as against what it usually is. The illustrations are abundant and the make-up is good.

MAZÛCK P. RAVENEL

An Introduction to Modern Statistical Methods—By Paul R. Rider. New York: Wiley, 1939. 220 pp. Price, \$2.75.

There are two ways of advancing the knowledge of a subject: (1) by gathering additional data about it, and (2) through a better understanding of the facts which are at hand.

The book under review is intended to help in the second way. It is written for whoever wants to use numerical data, without regard to what these data represent. It may be of help to health workers who feel they would like to have an advanced knowledge

of statistical methods, but it is hardly the book for those who want more information concerning the steps commonly employed. It says nothing of the need of a clear understanding of the limitations which should be placed upon numerical data, of the need of scrupulous accuracy in the collection of the facts which are to be used statistically, of the danger of drawing misleading inferences from a too limited supply and of the risk of attaching too much importance to statistical statements simply because they are statistical. Such matters are not within the scope of this volume. They belong to the kindergarten training of those who aspire to use such methods as are described here.

For those who have some knowledge of statistical methods already and want to improve and extend it in accordance with the best present-day practice, this book will be found to be a useful and authoritative guide.

GEORGE A. SOPER

Health Officers' Manual—By J. G. Geiger. Philadelphia: Saunders, 1939. 148 pp. Price, \$1.50.

Helpful quiz compends have often grown out of the necessities of administrative organizations. The manual from Dr. Geiger's hand seems to be no exception. For new employees entering a city health department without any vocational experience or training or familiarity with functions or duties to be performed, his little book will show him his way about.

As would be expected from its authorship and the city of origin the form of organization presented reflects the characteristics of the dual rôle of the San Francisco Department of Health under which hospital and other medical services for the sick are included as they are in Philadelphia and a few other cities in the United States. This does not illustrate approved health

department practice. Nor is it usually accepted that the issuance of food supplies to undernourished children should be a regular function of the health department.

Among the excellent and convenient features of this manual are the educational charts illustrating the natural history of communicable diseases. Also, one notes with satisfaction that births are expected to be reported within twenty-four hours, a much desired improvement over current city health practice in the United States.

This is not a book of general value for physicians or for graduates in public health, but is a convenient summary of the services of one of our best health-administered cities which lay groups of teachers and social or welfare workers on the west coast will find useful.

HAVEN EMERSON

The Clinical and Experimental Use of Sulfanilamide, Sulfapyridine, and Allied Compounds—By Perrin H. Long, M.D., and Eleanor A. Bliss, Sc.D. New York: Macmillan, 1939. 319 pp. Price, \$3.50.

The prominence which sulfanilamide and its allied compounds has rather suddenly attained during the past six years and the promise of their value in therapeutics in the future renders the intelligent clinical use of these compounds a matter of prime importance. The authors, as prominent workers in this field, have reviewed the investigations in this newest development in chemotherapeutics, and have outlined their own experiences. In eight chapters, they have covered the historical aspects of the subject; the chemotherapy of experimental bacterial infections; the experimental toxicity and comparative pharmacology of the several derivatives; the mode of action of the drugs; their clinical use; and finally the clinical toxic manifestations.

The historical development of the

subject is well handled and forms an interesting chapter, which should serve as a basis for an important addition to the general history of medicine. The chapters dealing with the experimental use of the drugs, dealing with many controversial subjects, are unavoidably concerned with many differences of opinion. The sections on the clinical use of the several derivatives cover most of the indications, and should be of material benefit to those not cognizant of the more outstanding papers in this field, although adding little to what has already been written. In these chapters, a well-timed definition of the several derivatives is given to clarify the confusion created by the multiplicity of trademark names attached to the various compounds. Wisely, too, is included a rather complete description of the use of the drugs in gonococcal infections with adequate discussion of the altered difficulties in the evaluation of criteria of cure of gonorrhea in the adult, with implications of the sociological importance.

The dangers involved in the use of these drugs are outlined in the section on clinical toxicity, which states very clearly the author's opinions of the significance of the various toxic manifestations, which will clarify this important phase of the subject to those unacquainted with it. Knowledge of the significance of the toxic manifestations is important not only in preventing the serious reactions which sometimes occur, but also in being able to proceed with what may be very important therapy in face of some of the drug symptoms, which are now known not to be contraindications. The importance of using these very potent, but potentially dangerous, compounds only under strict medical supervision is intimated in the chapter on clinical toxicity.

Throughout, the authors have upheld rather strictly their own interpre-

tations of both the experimental and clinical use of the compounds, even on those subjects which, at the time of writing, were quite controversial, and their criticisms of opposing viewpoints seem, at times, unwarrantedly and needlessly violent. As must be expected in a monograph written so early on a new and rapidly developing subject, much is unsettled, and conclusions cannot be too definite. Likewise, even in the short space of time elapsing between the writing and the publication of the book, many important contributions have been made, particularly in regard to sulfapyridine, but at this time the book appears to add a definite contribution to the general intelligent use of these important compounds. An extensive bibliography is included and the book is well indexed with both authors and subjects.

HENRY L. BARNETT

You're the Doctor—By Victor Heiser, M.D. New York: Norton, 1939. 300 pp. Price, \$2.50.

This is a book on personal hygiene based on the experiences of the author. The dominant note is that health depends more largely on correct eating than on any other single factor. Indeed, the author calls it the pivot about which everything else revolves. He explains that his own personal health is so good for a man of his age that he constantly has to explain what he has done to bring it about. This is a very weak argument as has been proved many thousand times. All of us can remember Fletcher and his fads, yet the world did not adopt his ideas about much chewing.

Each chapter has a name which takes the fancy and excites curiosity. "Where'er I Roam" is a survey of the different foods which the author has eaten in practically every part of the world. Perhaps the best chapter is the last, "A Merry Heart Doeth Good Like

a Medicine." There are many anecdotes collected from practically every part of the world. The advice given is generally sound. The book is interestingly written and will probably appeal to the public. It is being pushed on the reputation of the author's first book, *An American Doctor's Odyssey*, and the jacket gives some of the ordinary blurb which unfortunately disfigures so many books.

Some of the statements lack exactness. For example, the story of Pasteur's discovery regarding chicken cholera on page 55. Anyone reading this is entitled to believe that the author is speaking of the vibrio of Asiatic cholera and not the entirely different germ of chicken cholera. The lay public for whom he is writing will not recognize the difference and is entitled to a correct statement. The book is well printed and put together.

MAZYCK P. RAVENEL

Community Health Organization

—*Ira V. Hiscock, Editor (3rd ed.)*. New York: Commonwealth Fund, 1939. 318 pp. Price, \$2.50.

Hiscock has again given us a thoroughly revised and up to the minute edition of this valuable book. It is a work which all who toil in the field of public health have learned to welcome because it so gently and effectively broadens the vision, points out the challenges and opportunities of the coming decade, and establishes an active discontent with any *status quo* or *laissez faireism*.

This volume follows in general outline the editions of 1927 and 1932 and has its basis in the continuing work of the Committee on Administrative Practice of the American Public Health Association. It leaves the distinct impression that a community health organization which might be considered fairly good as of today or yesterday cannot rest on any laurels, for there is

much to be done, new work to be undertaken, with the goal well ahead, out of any immediate reach, if not perhaps even out of sight.

The reader sees clearly that quality of public health service is as important as quantity, in all the accepted usual range of community health work, such as venereal disease, tuberculosis, and general communicable disease control; school hygiene, the laboratory, and public health nursing. He lays down the book knowing full well that there must be a bold official approach to a more adequate provision for medical care. The editor makes it plain that in this and all health fields success will be most striking where there is a better knit and more active teamwork among many community agencies that heretofore have merely been on speaking terms with each other.

Recreation, housing, hospital planning, real industrial hygiene, all find their place in this helpful and stimulating new edition. Numerous type-specimen communities are there to beckon us on. No doubt there will be health officer readers who will water at the mouth over the suggestion of a month's vacation for health department staff members, and at some of the upper salary ranges as given at the chapter ends—perhaps enough to go out and work hard for some of these obvious desiderata.

HUNTINGTON WILLIAMS

Social Psychology of Adolescence

—*By E. DeAlton Partridge*. New York: Prentice-Hall, 1938. 361 pp. Price, \$2.75.

The author introduces his subject with the premise that, "since every agency dealing with young people approaches them in some kind of social setting, the significance of this social setting must be recognized if we are to understand the behavior of young people." He concludes that, "if one

accepts the point of view of social psychology, then the use of groups in treating behavior difficulties is of utmost importance. Since behavior arises out of the relationships surrounding the individual, the changing of behavior depends on a change in these relationships."

Between his premise and his conclusion the author surveys what he considers the more significant phases of sociology and psychology as they relate to young people in modern society. To be most fruitful, he says, the study of the adolescent must be the study of human beings growing up; the consideration of the process by which each individual becomes a social being.

Social psychology is by no means a new avenue of approach to the problems of youth. This book differs from many of its predecessors in the dynamic qualities of the organismic, or Gestalt, point of view from which it is written and in its practical suggestions for utilizing present, everyday social contacts and aspirations as means of working out the solutions to the problems of the normal adolescent as well as those of the "problem child" and the delinquent.

The book is addressed "to those who are working with young people." To those who have done considerable reading or have had wide experience in this field much of the material may appear elementary in nature. To all, however, the book will bring a freshness and vitality which make the reading of it a pleasure, and a positive, constructive approach which should be an inspiration to even the most experienced worker.

FREDERICK W. BROWN

Your City—By E. L. Thorndike.
New York: Harcourt, Brace, 1939.
204 pp. Price, \$2.00.

This book attempts to give a rating to the larger cities (some 310 of them) in the United States, on the basis of

what is called "goodness," and suggests that any city may be appraised by applying the same standards described.

Appraisal is not a new thing and has been applied quite extensively in the last few years to public health activities and facilities. When one is measuring the extent of services or the facilities available, the appraisal may not be overdifficult, but when an attempt is made to evaluate the quality rather than, or in addition to, the quantity, one is confronted with some real difficulties. In attempting to appraise not simply one feature of a city, but all features of any importance, the task becomes stupendous. Who is to determine just what is to be included and what excluded, and what relative weight is to be given to each item in determining the total score or comparative ranking? Thorndike has attempted an appraisal of "goodness" on the basis of 37 items.

While there are a number of characteristics that we would expect to find in any "good" city just as in any good person, it is quite questionable whether the number of automobiles or radios in use, or the number of beauty parlors, or many other items, can be taken as criteria by which to measure a city as to its wealth, progress, or desirability as a place in which to live. The author recognizes this.

The study may be interesting for those who wish to apply not all the 37 criteria, but the "Ten-Item City Yard Stick" (page 153) to their own city.

The book contains a great deal of valuable advice to those who would improve their city, and this advice rather than the more intricate variable and coefficients will be most likely to impress city administrators.

JAMES WALLACE

Social Welfare Laws of the Forty-Eight States—By Wendell Huston,

Compiler. Seattle: Wendell Huston Co., 1937. Loose leaf binding, 1,397 pp. Price, \$12.50.

This third edition, loose-leaf volume, brings up to date of time of publication the main social legislation, containing a vast amount of material well organized into a comprehensive volume. To public relief laws have been added labor laws. Following details of the Federal Social Security Act (with skeleton index), are given the laws of each state preceded by a useful index. While legislation relating to public health in the states is incomplete, the relative completeness of other phases of social legislation and the plan of arrangement make this volume a useful reference, especially for the administrator.

IRA V. HISCOCK

Un pays qui s'abandonne devant un danger qui grandit: l'alcool—By Dr. Jacques Parisot and Dr. Gabriel Richard. Nancy-Paris-Strasbourg: Berger-Levrault, 1939. 39 pp.

This is a study of the effects of alcohol from the social aspect, and concerns France primarily. The World War led to measures which greatly diminished the amount of alcohol consumed as a beverage. In less than 3 years after the Armistice the restrictive laws began to be attacked with the result that a greatly increased consumption of alcohol is now in evidence. The authors bemoan the fact that France leads in the annual per capita consumption—160 liters against 97 for Italy, 88 for Spain, 44 for Switzerland, and much less for other countries.

The factors chiefly responsible are: (1) excessive number of dramshops, (2) too much leisure, due to the 40 hour work-week, (3) privileges granted to distillers of brandy for private use, (4) use of particularly toxic drinks similar to, and the substitutes for, absinthe.

As remedial measures the authors

support the program of The Academy of Medicine which has been sent to successive administrations for 30 years: (1) modification or abolition of the privileges granted to private brandy distillers, (2) limitation of the number of dramshops, (3) increasing the tax on alcoholic drinks and suppression of those made with aniseed, or a reduction of their toxicity, (4) establishment of recreation centers in which only non-alcoholic beverages, fruit juices, and fruits in every form are served.

Ways and means are discussed. Some of the problems are common to all countries, some peculiar to France.

The arguments are well presented from a scientific standpoint, and the language is clear.

MAZÛCK P. RAVENEL

An Industrial Department of Health—By Northwestern University Medical School, Department of Industrial Medicine. Bull No. 9. Chicago: Northwestern University, 1939. 56 pp. Price, \$2.00.

This *Bulletin* attempts to put into brief manual form the opinions of many authors as to what constitutes adequate medical service in industry. It is carefully prepared, purposely brief but comprehensive.

Some 38.78 per cent of the entire population of the United States depends for a livelihood on a job in some industrial establishment (1930 Census). While sickness does not usually have a direct relation to occupation, it has tremendous economic results in decreased efficiency of workmen as well as otherwise. Management and labor are agreed that the maintenance of good health is of first importance. The medical and hygienic aspects are supreme but require the services of those in several specialties. Some 80 to 90 per cent of industrial groups are served by doctors in ordinary private

practice and the situation demands more or less special training so that recent graduates in medicine must serve a further apprenticeship of some kind. As a general rule physicians serving industry on a part-time basis is best. Outside of especially hazardous industries where the necessity of frequent examinations and check-ups is obvious, it is desirable that all employees be given a physical examination at least once every 3 years. A routine Wassermann is recognized as a valuable public health procedure but is not a prerequisite for employment. The bases for employment rejection are carefully outlined.

There is an occupational health hazard of some degree in almost every manufacturing process and the medical department must designate all conditions which adversely affect the health of workers. Most occupational health hazards are well known and easily recognized, also solvable by ordinary intelligence. General hazards are usually of major importance although specific hazards may be no less important for certain individual employees. Close coöperation with the state department of health is essential. Treatment is ordinarily a function of the individual or the community. Among all types of sickness disability, none requires more experience and knowledge than the differential diagnosis of an occupational disease, and it is imperative that medical service shall be competent in this field.

The significance of socialized medicine and insurance schemes which are rapidly extending over the country is given close comment. Attention is called to official governmental reports suggesting that some 40,000,000, or nearly one-third of the population, are receiving inadequate medical service.

Shop committees upon which labor is represented are necessary. The closeness of workmen to given local

problems and their intimate knowledge of men, machines, and danger points make for a high degree of effectiveness.

The reviewer finds few advocacies and statements which he would not endorse as outlined.

EMERY R. HAYHURST

When Social Work Was Young—
By Edward T. Devine. New York: Macmillan, 1939. 163 pp. Price, \$1.75.

This book records personal recollections of activities and conditions associated with the development of social work during the past 40 years, but especially between 1890 and 1910, including brief descriptions of the contribution of leaders in the movement. A chapter on prevention of tuberculosis, describing the significant rôle played by the Charity Organization Society in the advancement of educational and preventive measures and in the establishment of organizations will be of particular interest to public health workers.

IRA V. HISCOCK

Guiding Principles for Studies on the Nutrition of Populations—
By Dr. E. J. Bigwood. New York: Columbia University Press, 1939. 281 pp. Price, \$1.50.

The League of Nations Technical Commission on Nutrition has again sponsored a useful and enlightening publication. A complete and well outlined presentation of the points that should be stressed in conducting nutrition surveys of populations is given in this monograph. Nutritionists and dietary specialists will find this booklet of value in surveys of any size since the methods are applicable not only to groups of a few persons but to whole nations as well. A complete nutrition survey of any group of persons calls for an investigation of their food consumption. This purpose is adequately served in Part I in which are discussed

the types, methods and scope of surveys; the investigating staff; classification of foodstuffs; physiological value of the diet; economics; and statistical considerations.

Part II deals with how the state of nutrition should be studied in relation to diet. This section includes discussion of somatometric, clinical, and physiological tests and gives examples of the various types of surveys in a number of countries.

The author presupposes no advanced knowledge on the part of the reader and discusses nutritive principles, tests, and statistics with such clarity that both the student and the experienced worker will benefit.

An appendix contains numerous examples of record forms and tables used in the leading countries where dietary surveys have been made. The bibliography is efficiently up-to-date.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Finding Venereal Infections—Eminently sound and practical is this 15 year old V. D. case finding program which is recounted in matter-of-fact detail without fanfare. In at least one state, then, this essential work has gone on unobtrusively, year after year, even though some recently inaugurated epidemiologic projects have been reported with all the innocent enthusiasm of a Columbus bumping into a new world.

CASSELMAN, A. J., and CADWALLADER, A. Venereal Disease Contact-Tracing in Camden, New Jersey. *Ven. Dis. Inform.* 20, 7:185 (July), 1939.

British Attitudes on Social Medicine—To the question, "would a general medical service benefit the nation?" most (British) general practitioners would say "yes," says this ex-secretary of the B. M. A. who also says "yes." At the present time a complete medical service is quite out of reach of the great majority, and charity is not the solution of the problem. "Yes" says a medical officer of health. "Yes" said the discussants.

COX, A., and SCOTT, J. A. Would a General Medical Service Benefit the Nation? *J. Roy. Inst.* 2, 9:537 (Sept.), 1939.

For the Prevention of Shoulder Chips—Gold is sometimes found in unusual places. Here in an unlikely spot the health worker, whatever his job may be, will find some pure gold. True, the discussions are concerned with the water works and John Q. Public, but substitute whatever project may be your particular niche and you'll find the words of wisdom equally applicable.

CRIST, M. L. Public Relations. *J. Am. Water Works Assn.* 31, 8:1308 (Aug.), 1939.

Selling Health in a Skeptical Market—It is foolish to assume that healthy people generally are interested in abstract health. To be effective our efforts to influence health behavior must be individualized in terms of specific personal or group needs and aspirations. To recognize the limitations of our educational procedures may cause a better selection of methods, wisely concludes this author who must have come from Missouri.

DERRYBERRY, M. How to Influence Health Behavior of Adults. *Health Officer* 4, 3-4:114 (July-Aug.), 1939.

Primary Tuberculosis Is Protective—Evidence is presented to show that tuberculin reactors are less likely to develop tuberculosis when later exposed to infection than are those who are tuberculin negative.

FLAHIFF, E. W. The Occurrence of Tuberculosis in Persons Who Failed to React to Tuberculin, and in Persons with Positive Tuberculin Reactions. *Am. J. Hyg.* 30, 2:69 (Sept.), 1939.

Cement Dust's Bark Worse Than Bite—Compared to other dusty industries the hazard in cement manufacture is trivial. The incidences of tuberculosis and other chronic infections of the lungs were found to be less than those in the general population. Evidently prolonged inhalation of cement dust has no unfavorable influence upon tuberculosis.

GARDNER, L. U., *et al.* Survey in Seventeen Cement Plants of Atmospheric Dusts and their Effects Upon the Lungs of Twenty-two Hundred Employees. *J. Indust. Hyg. & Toxicol.* 21, 7:279 (Sept.), 1939.

Where Syphilis Will Soon Be Running Out of Disguises—Can you imagine any public health periodical being genuinely entertaining as well as informative? This review of recent statements should give rise to several broad grins—which is some kind of a record.

HARPER, C. A. Wisconsin's Health. State Board of Health Bull. 6, 15:3 (July-Sept.), 1939.

Eating Habits in the Orient—Observing the course of nutritional deficiency diseases around the world, this author has a wide background of unique and dramatic experiences with which to illustrate the universal damage done by defective diets.

HEISER, V. G. The Influence of Nutrition on the Diseases of Middle and Old Age. Sci. Month. 49, 4:304 (Oct.), 1939.

Curing TB. Individually and Socially—Collapse therapy for the tuberculous is not only an invaluable therapeutic measure, but it has a wide public health significance as well. Just as it offers the patient his best chance, so it offers the community its best protection. Hence health officials have an immediate interest in the wide extension of this measure.

HRUBY, A. J. Collapse Therapy of Tuberculosis. Am. Rev. Tuberc. 40, 3:255 (Sept.), 1939.

Effective Water Purification—From this excellent symposium on safety of public water supplies, one gathers that the number of outbreaks of water-borne disease are not due to inherent weaknesses in purification methods but in the failure to utilize standard procedures. A number of extremely practical questions are raised, and assured by a succession of authorities in this field.

NORCOM, G. D., *et al.* Symposium on Water Quality. J. Am. Water Works Assn. 31, 9:1475 (Sept.), 1939.

Who Was Sick and Why—How the National Health Survey was carried out and who did it, is explained in this paper which introduces a series of special reports, to be issued in the near future, on illness and medical care in relation to age, economic status, and employment; frequency of accidents in the home, in employment and on the highway; and adequacy of maternity services, status of housing, etc.

PERROTT, G. St. J., *et al.* The National Health Survey. 54, 37:1663 (Sept. 15), 1939.

Our Great Microbiologist—An appreciation of a distinguished American medical scientist by a French colleague, equally distinguished, constitutes a valued supplement to all that has been written about the man we all have long revered.

RAMON, G. WILLIAM HALLOCK PARK. J. Immunol. 37, 3:179 (Sept.), 1939.

Minimum, Adequate, Optimal Standards—We are reminded by this paper of the vulnerability of easy assumptions. Here in an institution where boys on an "adequate" diet, including the sacred quart of milk, together with fair amounts of basis foods, and these boys were found to be mostly within "normal" weight ranges. But when bananas were given as supplementary feeding to half the boys they made consistently better growth and development by every measure of physical status. Most significant differences were in blood ascorbic acid.

ROBERTS, L. J., *et al.* The Supplementary Value of the Banana in Institution Diets. J. Pediat. 15, 1:25 (July), 1939.

Measuring Diphtheria Prophylaxis Values—What is the best statistical method of checking efficiency of active immunization against diphtheria? What are the severity and clinical typology of diphtheria which occur in immunized children? For answers read this Chicago study which comments on un-

critical, but common, statistical assumptions.

SECKEL, H. P. G. Prevention of Diphtheria. *Am. J. Dis. Child.* 58, 3:512 (Sept.), 1939.

Teamwork—If the health officer will tell the teacher exactly what he would like to have his public believe and support, the school teacher ought to be able to work out the educative processes that will start school children on the road to believing and doing. How the two may work together is the subject of a provocative discussion.

SHEPARD, W. P. Sharpening the Focus in Health Education. *J. Health & Phys. Ed.* 10, 7:378 (Sept.), 1939.

Health Services for Tomorrow—Health articles are sometimes found far from their usual home in the scientific press these days. In this consumer's publication you may read a paper forcefully presenting the most telling arguments for a complete national health service. Let's forget the humanitarian reasons, urges the author, and turn our minds to the Nation's sickness bill of 10 billions. The capital value of preventable deaths, he says, is 6 billions.

SIGERIST, H. E. The People's Health. *Consumers' Union Reports* 4, 9:17 (Sept.), 1939.

Cancer Statistics — Reviewing British cancer statistics the author finds that the increasing crude death rates disappear (in women) when allowance is made for increasing age of the population. But the increase in males which defies age group correction, when considered by sites of the disease, suggests that the incidence of cancer of some organs may actually be increasing.

Here are some promising lines of approach.

SMALLMAN, A. B. The Cancer Problem. *J. Roy. Inst.* 2, 9:555 (Sept.), 1939.

Diver's Diseases — Apparently nature intended man to keep out of the water, else she would have provided him with selfclosing nostrils and ears, and fixed him up with a better temperature-control apparatus. This being the case, you had better respect the limitations of your physical equipment. What you can do to protect yourself is considered briefly.

TAYLOR, H. M. Otitis and Sinusitis in the Swimmer. *J.A.M.A.* 113, 10:891 (Sept. 2), 1939.

Wholesale Tuberculosis Examinations—British experience in mass X-raying by means of minicam photographs of the image on a fluorescent screen indicates that the method is both practical and inexpensive. A hundred and more cases per hour at an expense of about one cent each is reported.

THOMAS, A. R. Mass Radiography. *Pub. Health* 52, 12:1939 (Sept.), 1939.

Cutting the Toll of Congenital Syphilis—If, as the author says, "Every syphilitic baby is a failure of maternal education," and each year 60,000 syphilitic babies are born in addition to 25,000 stillbirths, then maternal education appears to be enjoying plenty of failures. As there are at least a million potential mothers infected with syphilis it would seem that health officers and educators have a job ready-made for them.

VONDERLEHR, R. A. Maternal Education, the Root of the Congenital Syphilis Problem. *Health Officer* 4, 3-4:118 (July-Aug.), 1939.

ASSOCIATION NEWS

OFFICERS, 1939-1940

President, EDWARD S. GODFREY, JR., M.D., Albany, N. Y.

President-elect, W. S. LEATHERS, M.D., Nashville, Tenn.

First Vice-President, ELISABETH L. SMELLIE, R.N., Ottawa, Ont., Canada

Second Vice-President, DOMINGO F. RAMOS, M.D., D.Sc., Havana, Cuba

Third Vice-President, WILTON L. HALVERSON, M.D., Pasadena, Calif.

Treasurer, LOUIS I. DUBLIN, PH.D., New York, N. Y.

Executive Secretary, REGINALD M. ATWATER, M.D., DR.P.H., New York, N. Y.

Chairman of Executive Board, ABEL WOLMAN, DR.ENG., Baltimore, Md.

The Annual Meeting in 1940 will be held in
Detroit, Mich.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Wendell C. Anderson, M.D., M.S.P.H., Bolte Bldg., Huntingburg, Ind., Director, District 2, State Board of Health

Millard B. Bethel, M.D., 160 S. Union St., Concord, N. C., Cabarrus County Health Officer

James C. Brabham, M.D., Box 13, Lexington, S. C., Lexington County Health Officer

Howard W. Hassell, M.D., 318 DeKalb St., Bridgeport, Pa., District Medical Health Officer, State Dept. of Health

Arthur W. Hopper, M.D., 356 Locust St., Washington, Pa., Washington and Green County Health Officer

Frank A. Moore, M.D., 701 College St., Trenton, Tenn., Gibson County Health Officer

Clifford C. Shoro, 61 Russell Road, Stop 5 Western Ave., Albany, N. Y., Administrative Finance Officer, State Dept. of Health

Eugene L. Speranza, 634 Fillmore Place, West New York, N. J., Assistant Health Director, City Health Dept.

A. H. Stewart, M.D., State Dept. of Health, Harrisburg, Pa., Deputy Secretary of Health

Laboratory Section

Salvador G. Aguilar, M.D., la C.P. Su Salvador, El Salvador, C.A., Head of Laboratories, Public Health Service

Charles P. Carpenter, Ph.D., 216 Laboratory of Public Health and Preventive Medicine, 34th and Locust Sts., Philadelphia, Pa., Assistant Professor of Public Health and Preventive Medicine, Univ. of Pennsylvania Medical School

Robert P. Gaines, Ph.G., M.A., 641 Broadway, Bayonne, N. J., Public Analyst

George F. Hadley, Ph.B., 1021 Ridge Ave., N.S., Pittsburgh, Pa., Analyst, City Health Dept.

Charles W. Rees, Ph.D., 8613 Cedar St., Silver Spring, Md., Senior Protozoölogist, National Institute of Health

Jorge E. Zepeda, M.S., Calle "La Fuente," Tegucigalpa, D. C., Honduras, C. A., Laboratory Worker, Direccion Gral. de Sanidad

Vital Statistics Section

Ralph C. Fletcher, M.A., 519 Smithfield St., Pittsburgh, Pa., Director, Bureau of Social Research, Federation of Social Agencies of Pittsburgh and Allegheny County

Marta Fraenkel M.D., 465 West 23rd St., New York, N. Y., Research Worker, Welfare Council of New York City

Jane Ward, A.B., 625 Goode St., Montgomery, Ala., Statistician, State Board of Health

Public Health Engineering Section

Paul E. Bishop, B.S., 6311 S. E. Clinton St., Portland, Ore., Sanitarian, City Health Bureau

Kenneth C. Chew, A.B., Route 1, Las Cruces, N. M., Sanitarian, District 4 Health Dept.

Gilbert H. Dunstan, M.S., Box 1996, University, Ala., Assistant Professor of Mechanics, Univ. of Alabama

George Feldman, B.A., 37 Fayette St., New Haven, Conn., General Inspector, City Health Dept.

Herbert H. Hasson, B.S., 58 Bowen St., Battle Creek, Mich., Project Engineer, W. K. Kellogg Foundation

Harold S. Hopler, B.S., Cheriton Point, Montoursville, R. D., Pa., Sanitarian, State Dept. of Health

Industrial Hygiene Section

Franklin J. Halpin, M.D., Surgeon, U.S.P.H.S., 2400 16th St., N.W., Washington, D. C., Medical Director, U. S. Compensation Commission

John Safford Wiley, M.S.E., State Board of Health, Indianapolis, Ind., Assistant Engineer, Bureau of Industrial Hygiene

Food and Nutrition Section

Lawrence L. Little, M.S., 3320 N.W. 13th St., Oklahoma City, Okla., Laboratory Technologist, Sterling Milk Products Co.

Ethel Austin Martin, National Dairy Council, 111 N. Canal St., Chicago, Ill., Director of Nutrition Service

Child Hygiene Section

Charles E. Presnell, D.D.S., M.S.P.H., State Health Dept., Jefferson City, Mo., Assistant State Dentist

Earl H. Ridgeway, O.D., 140 W. State St., Trenton, N. J., Optometric Consultant, State Colony, New Lisbon, N. J.

Public Health Education Section

Elizabeth H. Bohnenberger, State Board of Health, Jacksonville, Fla., Director, Bureau of Health Education

Margaret C. Donaldson, A.B., 581 Chestnut St., Meadville, Pa., Executive Secretary, Crawford County Tuberculosis Society

John E. Farrell, A.B., 106 Francis St., Providence, R. I., Executive Secretary, Providence Medical Assn.

Ira E. Foutz, 311 S. Juniper St., Room 507, Philadelphia, Pa., Assistant Executive and Publicity Secretary, Pennsylvania Tuberculosis Society

Jean Henderson, P. O. Box 210, Jacksonville, Fla., Public Relations Consultant, State Board of Health

Milton Rose, M.D., Laboratory of Hygiene, University of Pennsylvania, Philadelphia, Pa., Visiting Lecturer in Public Health, Univ. of Penna. Medical School

Harold W. Slocum, A.B., 348 College St., Burlington, Vt., Executive Secretary, Vermont Tuberculosis Assn.

Public Health Nursing Section

Gertrude Aufranc, R.N., M.A., County Court House, Mexico, Mo., Orthopedic Field Nurse, State Service for Crippled Children

Milada C. A. Botten, 1100 Donaldson Bldg., Minneapolis, Minn., Executive Secretary and Registrar, Minneapolis Nurses Assn.

Winifred Devlin, B.S., R.N., Michigan Dept. of Health, State Bldg., Lansing, Mich., Regional Supervisor

Frances A. Harris, R.N., 367 N. 21st Ave., Phoenix, Ariz., Public Health Nurse, State Board of Health

Lois L. Owen, Dept. of Public Instruction, Harrisburg, Pa., School Nursing Adviser

Rosemary Phillips, R.N., B.S., 7521 Byron Place, Clayton, Mo., Director of Nurses, St. Louis County Health Dept.

Epidemiology Section

Vlado A. Getting, M.D., M.P.H., 11 Perkins Square, Jamaica Plain, Mass., Technical Director, Mosquito Survey, State Dept. of Public Health

George H. Hodel, M.D., 1853 Park Drive, Los Angeles, Calif., Social Hygiene Physician, Los Angeles County Health Dept.

James H. Lade, M.D., State Office Bldg., Albany, N. Y., Medical Consultant in Syphilis Control, State Dept. of Health

Elroy F. McIntyre, M.D., C.P.H., State Capitol Bldg., Santa Fe, N. M., State Venereal Disease Control Officer, State Dept. of Health

Edwin Peterson, M.D., Bureau of Medicine and Surgery, Navy Dept., Washington,

D. C., Assistant, Dept. of Preventive Medicine
Nephi H. Savage, M.D., The Eaton, Apt. 204, Cheyenne, Wyo., Director, Division of Epidemiology, State Dept. of Public Health
Leonid S. Snegireff, M.D., M.P.H., 49 Maple Ave., Trenton, N. J., Medical Supervisor, Preventable Disease Control, State Dept. of Health

Unaffiliated

George A. Bunch, D.D.S., 925 Main St., Columbia, S. C., Director, Division of Oral Hygiene, State Board of Health
Charles Dubois, M.S., City Hall, Albuquerque, N. M., City Sanitary Inspector
Eleanor L. Hearon, M.A., 4200 E. 9th Ave., Denver, Colo., Director, Medical Social Service, Colorado General Hospital

DECEASED MEMBERS

A. H. Flickwir, M.D., Fort Worth, Tex., Elected Member 1921, Elected Fellow 1923.
McLeod Gillies, M.D., Charleston, W. Va., Elected Member 1935.
Charles C. Hopkins, C.E., Rochester, N. Y., Elected Member 1926.

Edward Vincent Murphy, M.D., Newport, R. I., Elected Member 1926.
Joseph C. Palmer, M.D., Syracuse, N. Y., Elected Member 1936.
Walter S. Stevens, M.D., Oklahoma City, Okla., Elected Member 1937.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, identifying clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y.

POSITIONS AVAILABLE

The Civil Service Commission makes announcement of examinations for the following positions:

Senior Medical Officer, \$4,600 a year
 Medical Officer, \$3,800 a year
 Associate Medical Officer, \$3,200 a year

Some of these examinations are for openings in the U. S. Public Health Service in the fields of venereal disease control and industrial hygiene.

Closing dates for receipt of application are as follows:

- (a) November 13, 1939, if received from states other than those named in (b) below

- (b) November 16, 1939, if received from the following states: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, Wyoming
- (c) March 11, 1940, if received from points in Alaska south of the Arctic Circle.

Necessary application forms may be obtained from the Secretary, Board of U. S. Civil Service Examiners, at any first class post office, or from the U. S. Civil Service Commission, Washington, D. C.

POSITIONS WANTED

Physician, M.D., Vanderbilt University; Dr.P.H., Johns Hopkins; experienced as epidemiologist, health officer and professor of preventive medicine, seeks position as administrator or epidemiologist. A397

Physician, M.D., Johns Hopkins; M.S.P.H., University of Michigan; experienced in school and city health work; for the past year director of county health department, seeks position as health director of city school system or in health service of a college or university. Will also consider position as epidemiologist or health officer in urban health department. A354

Physician, M.D., Syracuse University; postgraduate studies in bacteriology and immunology, will consider position as health officer or epidemiologist. Has served as director of county health unit, director of industrial hygiene and medical statistics and venereal disease field survey officer. A305

Physician, 32, married, M.D. 1936; postgraduate course in v.d. control, experienced as district health officer and in organizing and publicizing syphilis con-

trol campaign; now employed in charge venereal disease clinics in metropolitan health department; seeks v.d. control post with emphasis on organizational, investigative-survey or administration. M437

Young man, bacteriologist, M.S., Cornell; Ph.D., Rutgers; experienced in bacteriology, water supply, sewage, dairy and general public health laboratory work, extensive research in bacteriology and sanitary chemistry, high federal and state civil service ranking as bacteriologist, now employed as bacteriologist in eastern hospital; seeks responsible position in laboratory work or teaching of bacteriology, dairy industry or sanitary chemistry. L439

Experienced teacher in biochemistry and bacteriology; Ph.D., Iowa; now laboratory director in midwestern state; will consider teaching, executive or administrative position. L440

Physician, M.D., Loyola; 4 years' practice of industrial hygiene and surgery; former deputy state health officer; experienced in hospital administration, seeks position. M441

Positions Open

LABORATORY TECHNICIAN—County bacteriological laboratory; should be primarily trained as biochemist but familiar with routine clinical laboratory examinations; \$1,500-\$1,800, increasing; East. 110-PH, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH PHYSICIAN—Young man or woman physician, excellently trained internal medicine, for student health staff, exclusive junior college for women; appointment for one year, subject to renewal. 111-PH, Medical Bureau, Palmolive Building, Chicago.

COUNTY HEALTH OFFICER—Southern rural district; native southerner, or physician thoroughly familiar with the problems of the South preferred. 112-PH, Medical Bureau, Palmolive Building, Chicago.

RESIDENT SCHOOL PHYSICIAN—Recent graduate eligible; unmarried physician, American-born and trained required; school for boys; \$100, maintenance. 113-PH, Medical Bureau, Palmolive Building, Chicago.

CLINIC SUPERVISOR—Graduate nurse qualified to teach principles of public health nursing service to students in patients' homes; outpatient

department, large Texas hospital; \$125. 114-PH, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH NURSE—Graduate nurse, under 34, with 2 years' college training required; duties largely general duty in infirmary of large school for girls; \$100, meals. 115-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—Graduate nurse with postgraduate training public health for school health service; coeducational college, Michigan. 116-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH SUPERVISOR—Department of Health, midwestern state; considerable public health experience in addition to formal training required; beginning stipend vicinity \$2,100 (including travel allowance); increase within 6 months. 116A-PH, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH SUPERVISOR—Municipal public health nursing association; must be capable directing fairly large staff in heavy bedside nursing program; New England city of 50,000. 117-PH, Medical Bureau, Palmolive Building, Chicago.

Situations Wanted

BACTERIOLOGIST—Master's degree, eastern university; 8 years bacteriologist and instructor bacteriology, large municipal hospital; for further information please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—Graduate of fairly large training school; B.S. in nursing, University of Washington; certified public health nurse; 8 years, city and county health work; 2 years, director of nurses, child welfare organization; most recent appointment, consultant nurse in midwestern state department of health; for further information, please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

BACTERIOLOGIST—A.B., eastern school; M.S. and Ph.D. (Pathology and Bacteriology), University of Minnesota; several years' interesting research prior to graduate work; especially interested further research or teaching appointment; for additional information please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH PHYSICIAN—B.S., M.D., University of Minnesota; fellowship Public Health, Harvard University, with special attention to occupational diseases and industrial hygiene; 3 years, state department of health; for further details, please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

PUBLIC HEALTH DENTISTRY COURSE AT NEW YORK UNIVERSITY

A COURSE in public-health dentistry designed to meet the needs of dentists, dental teachers, dental hygienists, nurses, social workers and others who are interested in the scope and functions of social dentistry is being offered at New York University this fall as part of the program of the Division of General Education, according to Dean Ned H. Dearborn. Conducted by Dr. Alfred John Asgis, of the University's College of Dentistry, the course was to have begun September 26, to continue for 15 weeks.

CHILD STUDY ASSOCIATION INSTITUTE

A TWO-DAY INSTITUTE of the Child Study Association of America will be held at the Hotel Roosevelt, New York, N. Y., November 17 and 18, on "Controversial Areas in Today's Thinking About Children." There will be a preliminary session on November 16, for discussion of some of the problems of leadership, held at the headquarters of the Child Study Association, 221 West 57th Street, New York, N. Y.

Among the subjects scheduled for discussion are: "Habit Training as a Factor in Personality Development," "Psychotherapy in Childhood," "Intelligence Testing Today," "Radio Programs for Children—Recent Trends," and "Education at the Crossroads."

NEW YORK STATE INDUSTRIAL BULLETIN

THE State Department of Labor has resumed publication of its monthly, *The Industrial Bulletin*, with

the September issue. Because of the reduction by the 1939 Legislature of the Department's budget for 1939-1940 it has been necessary for the Department to curtail its expenditures for printing, and the July and August issues of *The Industrial Bulletin* were omitted and the number of pages for each issue for the remainder of the year materially reduced. In so far as has been possible, data from the reports which would have appeared in the July and August issues have been consolidated and are appearing in the September issue.

REVISED CARDIAC CLINIC DIRECTORY

A REVISED, up-to-the-minute directory of the city's affiliated cardiac clinics is just off the press and ready for general distribution, it was announced by the New York Tuberculosis and Health Association. The directory, compiled by the Heart Committee of the Association, covers the entire city, lists all cardiac clinics affiliated with the New York Heart Association, notes the clinic chiefs and social workers connected with each hospital, and quotes the hours the various clinics are at the public's disposal. For the first time, it carries a list of employment services and rehabilitation bureaus available to those suffering from heart disease.

The directory is for the use of social workers, public health nurses and teachers, and copies may be obtained free of charge at the offices of the New York Tuberculosis and Health Association, 386 Fourth Avenue, New York, N. Y.

FALLS IN HOME OUTNUMBER MOTOR ACCIDENTS

FALLS in the home caused the deaths of more persons in Iowa during the first 11 months of 1938 than did motor vehicle accidents, according to the State Department of Health. For this period, 462 deaths from falls were reported, as compared with 416 motor vehicle deaths.

The greatest toll of lives claimed by injuries from falls was in the age group of 65 years and older. In this group, 405 deaths were recorded, while motor vehicle accidents accounted for 106 deaths in this group, and 188 deaths of persons between the ages of 25 and 64.

Between 25 and 64 years, 42 deaths from falls were reported.

There were 10 deaths of children under 5 years of age, 3 in the age group of 5-14 years, and 2 between 15 and 24 years.

Polished floors, icy porches and front steps, loose rugs, and toys on the floor were given as causes of falls. Several children died from injuries sustained when they fell out of high chairs. Falling out of chairs, out of bed, and tripping were among the causes of death of persons in the oldest age group. The most unusual death was that of a woman who walked out of the house in her sleep and fell into a well. She was rescued but died of injuries from the fall.—*J.A.M.A.*, Sept. 30, 1939, p. 1338.

PERSONALS

Central States

DR. HARRY E. KLEPINGER, of Lafayette, Ind., has been appointed Health Commissioner of Tippecanoe County, succeeding the late DR. FRANK M. BIDDLE, of Battle Ground.

DR. WILLIAM M. MOIR, of Indianapolis, Ind., has been appointed Health Officer of Washington County and Bristol, Va., succeeding DR.

EARLE C. GATES, who will attend Johns Hopkins University for the coming year.

DR. AUGUST C. ORR, who has been Director of the Child Hygiene Division of the North Dakota State Department of Health, has been appointed Director of the Sixth District of the Michigan State Department of Health, with headquarters in Newberry.

RAGNAR T. WESTMAN, M.D., DR.P.H.,† of Minneapolis, Minn., has been appointed Director of Health in Kansas City, Kans., succeeding WILLIAM F. LUNSFORD, M.D., M.P.H.,† who died recently.

Eastern States

DR. WALTER G. ALEXANDER, of Orange, N. J., has been appointed a member of the New Jersey State Board of Health, Trenton.

LEONA BAUMGARTNER, M.D., PH.D.,† is leaving her position as Director of Public Health Training in the central office of the Department of Health, New York, N. Y., to become District Health Officer in the Kips Bay Health Center District, New York, N. Y., on November 15. Dr. Baumgartner will also be attached to Dr. Wilson G. Smillie's* Department of Public Health and Preventive Medicine of the Cornell University Medical College, New York, N. Y.

ROBERT P. FISCHELIS, PHAR.D.,† of Trenton, N. J., Executive Secretary and Chief Chemist of the Board of Pharmacy of the State of New Jersey, has been appointed a member of the New Jersey State Board of Health. The appointment comes at a time when a new State Food, Drug, and Cosmetic Act goes into effect in New Jersey, and the legislature has amended the State Health Act to add a pharmacist to the Board. Dr. Fischelis is the first pharmacist to hold this appointment, which is for

a 4 year term under the amended Act.

DR. ABRAHAM FLEXNER has resigned as Director of the Institute for Advanced Study, at Princeton, N. J., due to ill health. He will be succeeded by DR. FRANK AYDELOTTE, President of Swarthmore College, Swarthmore, Pa.

FREDERICK P. LEE, M.D.,* of Paterson, has been appointed a member of the State Board of Health, Trenton, N. J.

MORTON L. LEVIN, M.D., DR.P.H.,† of New York, N. Y., has been appointed Assistant Director on the Cancer Advisory Committee for the new New York State Division of Cancer Control, Albany, N. Y.

DR. CHARLES F. McCARTY, of Brooklyn, N. Y., recently Medical Director of the City Department of Welfare, has been appointed Associate Director of Medical Activities of the Medical Society of the County of Kings.

GEORGE ALBERT SOPER, PH.D.,* of Brookhaven, N. Y., Consulting Engineer, has been appointed a Consultant in the U. S. Housing Authority. He will actively supervise that phase of USHA housing management concerned with collection and disposal of waste in the public housing projects; and will serve as consultant in public sanitation to local housing authorities in establishing methods of ground maintenance as a joint enterprise of managers of public housing projects and tenants.

Southern States

DR. ALBERT L. BALL, of Gallatin, Tenn., has been appointed Health Officer of Bradley County, to succeed WILLIAM V. SANFORD, M.D.,† of Cleveland, resigned.

DR. JAMES C. BRABHAM,† of Johnsonville, S. C., has been appointed Health Officer of Lexington County.

This county was formerly joined with Calhoun County in a health unit under the direction of FRANKLIN L. GEIGER, M.D.,† of St. Matthews, who remains in Calhoun County.

GEORGE F. BROCKMAN, M.D.,† of Louisville, Ky., has been appointed Health Officer of Muhlenberg County, to succeed DR. NEALE M. ATKINS.

DR. PHILIP R. CRONLUND, of Washington, D. C., has been named Health Officer of Lee County, to succeed DR. JAMES M. SUTER, of Jonesville, who will attend Johns Hopkins University for the coming year.

DR. WILLIAM A. DODSON, JR., of Fayette, Ala., has been named Health Officer of Winston County, succeeding DR. PAUL H. HILBERT, of Double Springs, resigned.

DR. THOMAS S. ENGLAR, of Baltimore, Md., has been appointed Health Officer of Albemarle County and Charlottesville, Va., succeeding ROBERT D. HOLLOWELL, M.D.,† who has gone to Shelby County, Tenn.

DR. CLAIR A. HENDERSON, of Dawson, Ga., has resigned as Health Officer of Terrell County, to become Assistant Health Commissioner of Savannah.

DR. JAMES ROBERT HENDON has been named to succeed GRADIE R. ROWN-TREE, M.D., C.P.H.,† as Director of Activities in Venereal Disease Control of Louisville, Ky. Dr. Hendon has been Acting Director of this Division.

DR. PAUL H. HILBERT, of Double Springs, Ala., has resigned as Health Officer of Winston County, to join the Health Department in Cincinnati, Ohio.

ROBERT D. HOLLOWELL, M.D.,† Health Officer of Charlottesville and Albemarle County, Va., has been appointed Health Officer of Shelby County, Tenn.

ARCHIE B. HOOTON, M.D.,† of Upper Marlboro, Md., has been made

Health Officer of Allendale and Hampton Counties, S. C., taking over part of the work of Dr. LOUIS T. CLAYTOR, who has been in charge of these counties as well as Barnwell and Bamberg Counties. Dr. Claytor will remain as Health Officer of the latter two counties.

DR. JAMES A. LOVELESS, recently of Chattanooga, has been appointed District Health Officer of Rhea-Meigs County, Tenn., succeeding EDWIN N. HALLER, M.D.,† of Decatur.

DR. GEORGE E. MADDISON, of Monroeville, Ala., formerly Health Officer of Monroe County, has been appointed Health Officer of Henry County, succeeding Dr. CARL T. MARTIN, of Abbeville, who resigned to enter private practice.

DR. MARVIN E. McRAE, of Richmond, Va., has been appointed Health Officer of Pittsylvania County, Va., succeeding Dr. EUGENE B. SHEPHERD, of Chatham, resigned.

GRADIE R. ROWNTREE, M.D., C.P.H.,† who has served as Acting Director of Health of Louisville, Ky., in the absence of HUGH R. LEAVELL, M.D.,† during the past year, has now been appointed Assistant to Dr. Leavell.

DR. PRICE SEWELL, JR., formerly of Jackson, has been appointed Director of a new health unit in Owen County, Ky.

Western States

DR. FLOYD W. BAUGH, of Burlington, Wash., has been appointed Health Officer of Skagit County.

DR. LEROY L. FATHERREE has been ap-

pointed full-time Health Officer of Little Rock, Ark., to succeed the late THOMAS M. FLY, M.D.†

DR. JOHN T. HERRON, of Little Rock, Ark., has been assigned as Health Director of the district composed of Ashley, Desha, and Chicot Counties.

THOMAS D. MENSER, M.D.,† of La Junta, Colo., acting head of the Otero County Health Department, has been appointed Director of the new city-county public health unit in El Paso County, with headquarters in Colorado Springs, Colo.

DR. WILLIAM E. STEELE, of Longview, Wash., has been appointed Chief Medical Adviser to the Washington State Department of Labor and Industries, a position he held several years ago.

DEATHS

A. W. FLICKWIR, M.D.,* Health Officer of Fort Worth, Tex., died July 26, 1939. Dr. Flickwir, who became a member in 1921 and a Fellow in 1923, was a member of the Health Officers Section Council and a member of the Governing Council of the American Public Health Association at the time of his death.

HARVEY CUSHING, M.D., distinguished brain surgeon and educator, died in New Haven, Conn., October 7, at the age of 70.

JOHN W. McINTOSH, D.P.H., M.B.,† Senior Medical Health Officer of Vancouver, B. C., Canada, died recently.

Health for Three-Thirds of the Nation*

EDWARD S. GODFREY, JR., M.D., F.A.P.H.A.

*President, American Public Health Association; State Commissioner
of Health, Albany, N. Y.*

THE choice of my subject this evening has been motivated primarily by the stress given at the National Health Conference of 1938 to the plight of that one-third of our nation which is attempting to exist on an average family income too small to provide the food, clothing, shelter, and medical care needed for the maintenance of health. It is motivated further by the tendency of later public discussion of medical care to center about this lowest economic group and the marginal group just above. It is motivated by this tendency to confuse the health service which was designed to serve the public as a whole, with other services designed to benefit only certain economic and occupational groups; by the tendency to confuse public health medicine with relief medicine, including under this term the various types of sickness insurance that have been proposed.

It is, of course, one of the teachings of public health administration that the

health department should apply its efforts where the need is greatest and most immediate and where the returns are greatest in life saving and sickness saving. It does not follow, however, that legislation for health should be addressed to segments of the population, classified according to income or occupation. Certainly, there is a grave danger to both the quality and the quantity of the services for the health of the entire people, when public health work is associated administratively with agencies dealing exclusively with low income groups of the population. Public health is something which should grow. Agencies for relief are something that should disappear.

The effects of immediate medical relief are tangible; of prevention, intangible. The former has a strong emotional appeal. The latter is rarely well appreciated, even by those whom it benefits most. The former commonly has first call on the taxpayer and the contributor to philanthropy. Its demands for medical care run into hundreds of millions of dollars annually. The public costs and the private costs of

* Presidential Address presented before the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 17, 1939.

medical relief are many, many times greater than the funds spent by taxpayers and philanthropy for preventive health services.

The public has become used to spending—not only in recent years—on this scale for medical relief. Hence it is that in any competition for appropriations, prevention nearly always gives way to relief. The comparatively little more money needed to convert relief medicine into public health medicine is not obtained unless there is continuous and insistent pressure for it.

Medical relief, with rare exceptions, looks not to what lay back of the immediate difficulty, nor to what lies ahead for the individual or the family concerned, but deals solely with the immediate problem of the care of a sick or injured individual. This is as true of private practice as of public or quasi-public practice. Concentration of attention on the cost of medical care and relief from its burden is likely—to use a phrase of President Roosevelt's—merely to stimulate further “bailing of the boat, rather than calking of the seams.”

The only safeguard that would seem to insure continuance of a dynamic public health movement, and to insure that any governmental expansion of medical services has the improvement of public health as its primary objective, is to place the administration of any such expansion squarely upon the shoulders of departments of health—national, state, city, and county. When this is done, these health departments must of course, be given the necessary increase in moral and material support that will enable them to deliver public health medicine and not merely relief medicine. Given this, they should be held responsible for results and must not evade that responsibility.

Health authorities should have increasing opportunity as soon as possible to acquire experience in the delivery of

medical care. When given the opportunity, it should be developed along public health lines, bringing all the necessary available forces of the health department into play. By this I mean, not only giving the best possible in diagnosis and treatment, but also in looking for the causes of disease or accident and in correcting them if possible; in looking for further opportunities for preventive services in the home and among the family. It is this kind of medicine that I mean when I speak of public health medicine.

Let it be recognized clearly, however, that there remain many immediate services in the field of prevention that should be supplied. There are many imperfections of organization in the national, state, and local health services for their present duties and functions that can and should be corrected. Perhaps we might better examine some of these before calling attention to the imperfections elsewhere.

In the national government, the division and dispersion of health functions among the Public Health Service, the Children's Bureau, the Bureau of the Census, and the Food and Drug Administration are so well known to state health administrators that I shall not comment. They are all agencies with which state health departments have to deal. The recent transfer of the Public Health Service to the Social Security Administration did nothing to simplify this confusion nor to coordinate these functions.

The proposals of the Wagner bill (S. 1620) did nothing to correct them. In fact, its proposal to place the administration of any federal aid for medical care, and hospital and health center construction under the Social Security Board only added to the complexities. The proposal to have the Department of Labor administer federal aid for industrial hygiene, if adopted, would cap a climax of chaos. It remains to be

seen whether groups with special interest in one or another special phase of public health are sufficiently broad in their concepts and clear in their desire for health for everyone to aid in producing an inclusive national health program under a single authority at the national level.

At the state level, we find such a variety of divided authorities dealing with health matters that it is difficult to devise a classification. In one state, the health department is not even responsible for the collection of vital statistics. In certain states, there are separate agencies for crippled children. Food, drug, and cosmetic control finds a place in fewer than half the state health departments; school medical inspection is supervised by the state education department in a number of states; industrial hygiene is a function of labor departments in 2 of the 25 states that make any provision for this important work. With few exceptions, even the services provided by states for the control of tuberculosis are not concentrated in the state health department, and too often any state program adjusted to the importance of this disease is altogether lacking.

To bring these deficiencies of health organization, public and private, down to the local level would merely add to the picture of confusion and emphasize further the deficiencies of functional services. Some voluntary organizations, for instance, interested in particular phases of public health, are performing duties properly belonging to the local health department. Too often they continue to perform these functions while doing little or nothing to build the health department up to a point where it is capable of administering the function effectively. The fault, no doubt, lies as often with the health department as with the agency.

Let me make it clear that this criticism does not refer to the philan-

thropic organization that provides for a demonstration that operates through a government agency, which serves notice that it will get out at a certain time and, when that time arrives, gets out. Such agencies are looking to the up-building of useful governmental functions, *by government*. They are not designed as mere palliatives for social ulcers, which an immature political government may be incapable of recognizing or treating, until it has been shown how to do it.

Nor does it refer to those agencies which aid and promote the proper development of public health authorities by building up public opinion for their support and organizing the interest of citizens for effective action through education. As permanent auxiliaries, they are probably of even greater importance than the "demonstrating" agency.

Perhaps it will be thought that I unduly emphasize the importance of proper organization. I think not. Sound organization means economy and efficiency. Lack of it means waste and inefficiency—waste and inefficiency, not only in expenditure, but in the competition to obtain funds. It means waste and inefficiency in overhead, in duplicating and overlapping services, waste in the effort to fill the gaps between doubtful borders.

The deficiencies of existing public health services are not things we health officers want to hide from the public. We want the public to know them and to correct them. We need better, more specially educated personnel, more facilities and better organization. Though the triumphs of public health have been many, reiteration of them is likely to lead to the impression that the job has been done. There are those who believe that public health work should be limited to sanitation of the environment, and to the control of communicable diseases through immunization of the susceptibles and restriction

of the infected. They profess to see a sharp distinction between curative and preventive medicine, between functions which may properly be operated by health departments and those which belong either to another department of government or are the exclusive reserve of private medical practice and medical philanthropy. Events tend constantly to disprove the accuracy of their vision. Experimental effort disproves the accuracy of their prophesies.

It has always been thus. Not one single advance in public health has failed to encounter opposition. The reporting of communicable diseases, from typhoid fever through tuberculosis, to syphilis and gonorrhea, was opposed by many doctors; the purification of public water supplies, by taxpayers and private water companies; the installation of sewers and sewage treatment works, by taxpayers and industries of the offending communities; milk control by milk producers and dealers, as well as a deluded minority of their customers; free laboratory service, by established private laboratories; school medical examinations, by school trustees, physicians, parents, and school superintendents; the establishment of well-baby, orthopedic, tuberculosis, venereal disease, and children's clinics, the employment of public health nurses, and the establishment of county health departments, by interested minorities of the medical profession. All have had to meet and overcome, not merely inertia, but active opposition.

Of course, always there has been support for these measures by progressive, socially minded doctors. Not many advances would have been possible without them. Often they have assumed *leadership* in the struggle. This is not a grudging admission. It is a declaration by one who has good cause to know what this kind of medical man has contributed to every

advance. It is the intransigent conservative who usually obstructs. Always these opposition groups are abetted by a group of short-sighted taxpayers unwilling to spend an immediate dime to save an ultimate dollar.

We who are in public health do not believe we have been led to a consideration of the spread and the quality of medical care by any desire to increase our prestige, our influence, or importance. Consideration of this problem has been forced upon us by the evidences of neglect, of non-treatment, mistreatment and maltreatment, that have been thrust upon us in the course of our daily work. As medical men and women, as nurses, medical social workers, we see daily the results of poverty, ignorance, fear, pride, and what seem to be the shortcomings in our existing system, or lack of system, of medical care. We see the cases of tuberculosis that have reached an advanced stage before recognition or at least before receiving efficient care; cancers that have metastasized before receiving a competent medical examination.

We see the results of that pride which has prevented self-respecting individuals from asking for medical care which they cannot pay for, until dire necessity forces them to ask. We have seen cases of recognized tuberculosis refuse sanatorium treatment because their inherent dignity refused to submit to the dime searching investigation demanded by short sighted officials who wrongly think that the voting public demands this parsimony even in matters of life and death.

It is difficult to reconcile the opposition of so many physicians to free syphilis clinics with the spirit of the Hippocratic oath and the first section of the Code of Medical Ethics, which declares in essence that the care of the patient is the primary consideration; that the compensation of the physician

is subordinate. Why must an unfortunate's scanty resources be exhausted on a few inadequate weeks of private treatment, before he becomes eligible for a free clinic, if such exists; why is the treatment of so many patients terminated when their funds are gone, without even a suggestion that they go to a clinic.

Why does a profession, which presumably has made some study of human psychology, fail so largely to appreciate the real mental distress of most persons in admitting economic defeat, which is implied in asking for free medical care under our present system; and why, if it be recognized, is a profession which is essentially humanitarian, so inconsiderate? Why is there such insistence on the "fee-for-service" method of payment? A rational explanation of the opposition to free medical care by the government is in part due to the quality of the physicians and the services that have so often been rendered in the past under the "poor doctor" contract system. In greater part, however, it lies in the exploitation by both government and philanthropy of (1) the desire of the true physician to improve his knowledge by wider experience even at great self-sacrifice; (2) his ambition to achieve a justified prestige among, not only the public, but his fellows of the profession; (3) the profession's effort to adhere to a custom, consonant perhaps with the days when medicine was more largely pastoral, but which is utterly inconsistent with the scientific and technical advances of the past quarter century.

The "personal relationship" argument has been overplayed. The kindly physician "with a heart of gold" who "grannied" the children but practised the medicine of his student days, is no substitute for the doctor who uses the knowledge and instruments of modern science. I want no "pastoral" medicine in mine, until the scientific resources

of diagnosis and treatment have been exhausted.

We public health people see many instances where the fee-for-service system of payment has interfered with the rendering of a complete health service. The interference is not merely the payment for the primary call, but the inhibition imposed on the physician against offering or suggesting services for other obvious needs of the individual or his family. Such an offer with a fee in sight, may be interpreted as seeking business; an offer without expectation of fee, as chiseling, cutting prices, and unfair competition. It is doubtful that any amount of public health education can overcome the economic and psychological barriers imposed by this "fee-for-service" system, and its alternative of "pauper" care. There must be something better.

For my own part I want to reiterate my resentment of the imputation, implied or explicit, that a salary stultifies, that a fee must be received or expected for every service rendered or it will be rendered grudgingly, inefficiently, or both; that men and women in public service are any less worthy in education, in capacity, in interest, in devotion to duty, than those who are in what we call "private life." I resent the imputation that no medical health officer ever worked overtime, exercised any independent judgment, or is anything more than a robot motivated by a monthly salary check.

In a recent address a prominent exponent of "organized" medicine asked the rhetorical questions whether we wanted England's, Hitler's, Stalin's, or New Zealand's medicine, or American medicine; whether we wanted socialized, state, or democratic medicine. Since the questions were obviously rhetorical, the expected answer was equally obvious that we wanted American, democratic medicine. Just what American, democratic medicine would be was not

explained. It may be well to raise that question. Possibly it might mean democratically administered state or socialized medicine, and it might include elements contained in or drawn from the systems of the various countries mentioned, or others.

In spite of the propagandist questions and implied answers of opponents of change typified above, we may well ask ourselves seriously what is American democratic medicine, and how may it or should it develop to be something truly American, truly democratic, and truly medicine in the best sense of the word. My answer is that it must be public health medicine, which means that it is preventive as well as curative medicine; that it is medicine delivered without distinction as to race, creed, occupation, or income; that it is for no less than three-thirds of the people.

It is typical of American government that it proceeds through legislation in response to a public demand. When mistakes are made in legislation they are rectified when they become apparent to a sufficient body of the voting public. This applies whether the error be inherent in the legislation or whether it fail to provide sufficient safeguards against administrative abuse or inadequate fiscal support. Important legislation involving large social or economic change is always accompanied by public hearings where expert testimony and the views of those interested in the probable effects of such legislation, whether they be thought good or bad, may be heard. If the subject be controversial there is further debate by the legislative body itself before a final vote is taken. All this is part of what we call "the democratic process."

Anything, therefore, which becomes law after being duly considered and enacted in this fashion by an American legislative body, provided it is constitutional and legal, *is* American and *is* democratic. "Name calling" cannot

make it otherwise. It seems necessary to labor this point because so many seem to have such strange and erroneous impressions as to what is democratic and what is American. They do not think of, or do not know, of the many things in our government, our laws, jurisprudence, customs, and culture which derive from foreign sources. Until a generation ago the education of the American physician was hardly considered really complete until he had studied in Europe. The things we have brought from abroad we have adapted to our ways and we usually improved them. There is no reason why we should not in our own way, adapt, develop, and improve any form for the social reorganization of medicine that may be suggested by the results of the experience of other countries.

One thing we appear to need badly is American experience acquired through experiments, experiments that bring the health departments definitely into the picture. I doubt the health department need be concerned with experiments in medical indemnity insurance, since the common requirement that the first calls be made at the patient's own expense—*i.e.*, are not indemnifiable—tends to defeat the public health objective of prompt early diagnosis and care. It seems doubtful that such plans will ever reach the border-line income group on a *voluntary* basis, or will ever obtain popular confidence and support for a *compulsory* basis.

It seems entirely proper, however, for health departments to take a greater interest in the work of hospitals and groups giving medical care on a prepayment basis. Coöperation with the latter, should be predicated on the physicians employed being qualified for the services they are to render and ethical in the true and best sense of that term. I would say they should conform to the principles of ethics of the American Medical Association if

the fourth and fifth features, which make contract practice unethical, were more reasonably interpreted than they have been at times in the recent past. These are the features relating to reasonable competition in the community and "free choice of physician." That the patient's choice may not be a good choice has been abundantly demonstrated not only by the pecuniary success of blatant quacks, but by the experience of many communities paying for welfare cases on the fee-for-service basis. How could it possibly be otherwise when the patient has so little information on which to make a choice and receives so little help in making it.

"Reasonable" competition is a matter of opinion. It would seem that if this question is applied to the competition provided by a group of physicians organized under a prepayment plan, that decision should rest on the adequacy of compensation paid to the physicians in the group and of the facilities provided for their use. The quality of the service rendered would appear to be a proper basis for the group's competition with the profession as a whole, just as it is supposed to be between those in private practice.

There is greater need that state health departments interest themselves more keenly in the medical services rendered in connection with recognized fields of public health. The more extensive operation of government owned and operated tuberculosis hospitals under health departments would help bring all the forces of both groups into closer relationships and be mutually stimulating. The clinics for venereal diseases operated by local governments or with government aid have improved so materially in recent years that there is every encouragement for further expansion until the current needs are met competently and decently.

The improvement has been not only in the quality of treatment given but

in better surroundings, more sessions and personnel, thereby permitting more time per patient. Both patients and doctors are better satisfied; there are fewer delinquencies; less effort is needed for the follow-up. Under the direction of the health department, generalized public health nurses are available for the necessary field services, are in closer touch with the clinic's problems, and come to a better appreciation of the venereal diseases as a public health problem. This is a development along the line of what I have termed public health medicine.

The services rendered in many health department clinics compare favorably with those operated by voluntary hospitals. As compared with general practitioner service, it is highly probable that better histories are taken, more sources of infection and contacts are examined and treated, more general physical examinations made, and better and more continuous treatment given.

Time will not permit of anything more than mention of how free public laboratory service has increased the use of laboratory aids to diagnosis; how well-baby and children's clinics have improved the examination of such children when brought to private practitioners; how prenatal clinics have increased the use of pelvimetry and taking of blood pressure; likewise, how orthopedic clinics have led to earlier recognition of and consultations for crippled children.

But in every advance that has been made in these services that lie outside the traditional field of environment and contagious disease, health departments have had to step with extreme care lest they violate or seem to violate or be charged with violating some assumed privilege or prerogative of the medical profession. While many conscientious physicians oppose the so-called "encroachments" of public health into clinical medicine, many of them are not

aware of the existing shortcomings of private practice in protecting the public interest, and some of them refuse to recognize the validity of any evidence that runs contrary to their opinions.

The present opposition of so-called "organized medicine," or of its spokesmen, to the expansion of public health service rests on grounds that are hardly tenable. These grounds of opposition are stated in a sort of *obiter dictum* purporting to explain the second principle of Chapter IV of the Code of Medical Ethics. This chapter relates to the Duties of the Physician to the Public, and the principle covers the subject of Public Health. I quote:

The profession has resisted the efforts of some public health officials and employees to extend their work into the direct practice of medicine among individuals. Opposition to such practice is based on the already often repeated principle that medical relations are among the most personal and confidential of all human relations. They cannot be created in any satisfactory form between an official department or institution and an individual.¹

These views rest fundamentally upon an inadequate concept of what the field of public health does and should comprise. The reasons given for opposing expansion are inadequate. The evidence obtained from experience demonstrates that satisfactory personal relationships have been maintained between physician and patient in many government medical services. The objections cited will not suffice to dam the current of public opinion which is becoming impatient with delay, and demands expansion to meet the obvious needs.

It is an American custom to leave matters to private initiative and performance until the public becomes convinced that a public agency can do it better or more adequately. Our fire departments evolved from the volunteer companies whose actions today evoke amusement. There are still volunteer fire companies, and fire insurance com-

panies have developed their "protectives." The major functions of our police departments were formerly performed by private police or agencies selling their services to the private buyer. There still are private detective agencies.

Our vast system of public education has developed from the church, private and "pauper" schools established in Colonial days. In the second quarter of the last century—one hundred years ago—the struggle to secure free public education was second only to the question of slavery in the controversies of the northern states. Free public schools have won everywhere. But there are still private schools for those who wish to use them. The objective was not to abolish non-public schools, but to make certain that for every child there was an available school which he could attend without injury to his sensibilities. The arguments used in the controversy over the free school system are almost counterparts of those used today in the discussion of the expansion of government participation in medical care. It was argued that free public schools would halt improvement—ruin the existing private schools—and, above all, pauperize the people. Though some private schools went out of existence, many became part of the public school system. The system did not halt progress and it did not pauperize the people.

CONCLUSION

I fear that I have offered little in the way of constructive criticism, except possibly by way of implication and suggestion. If so, it is because I do not know all the answers. I have read, I have sought advice, I have searched my own experience. Some things seem clear, others hazy.

Although the *Minority Report* of the Committee on the Cost of Medical Care and the attitude of the official *Journal*

of the American Medical Association make it seem improbable, something might be gained by a conference which would review the findings of that committee, the national health survey, and the survey conducted under the American Medical Association and its subsidiaries. It is doubtful, however, in view of the incomplete and distorted information the *Journal* has published, and the reliance so many of the medical profession have placed on it as a source of information on both the technical and sociological aspects of medicine, that any important change of attitude can be expected from such a conference. Nevertheless, I offer the suggestion in the hope that there may be constructive guidance in an American, democratic spirit in the effort to legislate for a national health program. Persecution and prosecution will not answer our purpose.

Most of us medical men who practise the specialty of public health have been in private practice. We know the ways of practice as it is actually practised. We know its trials and diffi-

culties. We recognize its accomplishments. We want no cheap medical care. We are for adequate compensation for qualified practitioners, not mere "soup-bone security" nor a mere "living" wage, but a compensation compatible with the education and culture required of a doctor, and bearing a direct relationship to the responsibilities that are involved in his daily work. We believe in compensation for doctors working in hospitals, clinics, and dispensaries, and for those giving free services in their offices and in patients' homes. We are for, not only high standards of medical education, but high standards of medical care and advancement of those standards in accordance with the discoveries of medical science. We are for a system of medical practice and a system of public health administration and public medical service that will achieve our hope and our goal of the best possible health for three-thirds of our people.

*Chief, Division of State Coöperation, Food and Drug Administration,
U. S. Department of Agriculture, Washington, D. C.*

IF we were to adhere strictly to the title of this paper it might be concluded after a careful scrutiny of the Federal Food, Drug, and Cosmetic Act that its provision are few so far as public health—in terms of preventive medicine—is concerned. While the Act does not parallel that type of legislation common in state laws and in municipal ordinances which demands that market milk and cream shall be pasteurized and produced only by tested herds found to be free from disease, it does, however, embrace provisions which affect the public health and which are bound to afford our citizens an increased measure of protection. In a paper presented to this Association 12 years ago, the present speaker discussed the public health feature of the Act of 1906. Briefly, the conclusions, after 20 years' enforcement of that statute, were to the effect that essentially the only public health features were those which forbade the introduction of poisonous or toxic substances in foods in such amount as would render the food injurious to health, and the general provisions against the interstate shipment of food contaminated with filth, as well as food which was the product of a diseased animal. The drug sections of

that Act related essentially to misbranding and were practically ineffective so far as public health protection is concerned. The Act of 1938 has made a definite step forward in the field of foods, drugs, and cosmetics which promises a definite measure of protection from the standpoint of public health.

Taking up first of all the food section of the Act (402(a)(1)), we find that a food is now adulterated if it bears or contains any poisonous or deleterious substance which may render it injurious to health. Under the Act of 1906, this was not true, for, to cite one instance, under that Act the interstate shipment of mussels, fatal to humans at certain times of the year, if not misbranded could not be prohibited. Our only action under that law was in the case of foods to which man had added a poisonous or deleterious ingredient. Furthermore, a section of the present Act reiterates this prohibition of naturally dangerous food, and in addition directs the establishment of a safety limit or tolerance in the case of foods which cannot be produced or manufactured without the addition of some toxic material. An example here, of course, is illustrated by those fruits and vegetables which, to insure a crop at all, must be sprayed with some material such as arsenate of lead. Perhaps a more striking feature

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 17, 1939.

with respect to protection is that section of the new law which authorizes the Secretary of Agriculture to establish a system of control by the issuance of permits. The condition under which this licensing system may be established is represented by a food establishment where there is the possibility of contamination with microorganisms and the safety of the food emanating from such establishment cannot be adequately determined by objective examination. In other words, if a food establishment is so conducted that there is the possibility of contamination of the product with microorganisms and the resultant product likely to cause sickness before examinations can be completed, then, and then only, is the Secretary of Agriculture authorized to forbid such shipment from such establishment until the issuance of an official permit. Less drastic perhaps is the clause which declares food to be adulterated if it is produced, manufactured, or handled in an establishment in a manner whereby it may become contaminated by filth. Still another new provision rules out containers for food which by their composition may contaminate the contents. The misbranding section which applies to food requires among other things that in the case of a food composed of two or more ingredients and for which no standard of identity has been established the label shall disclose the common or usual name of each ingredient, except a collective declaration for spice, flavoring, and color. This provision of the law rigidly enforced should afford a valuable guide to those unfortunate consumers who are allergic to specific items in the dietary.

Since nowadays the public is educated along scientific lines by feature articles in the press as well as by radio, the term "vitamin" has become a household word and claims for special diets are widely heralded—so much so

that Congress has ruled that foods for special dietary purposes or those bearing vitamin claims shall be adequately labeled to inform the purchaser as to their value for the uses claimed, and the Secretary is authorized to prescribe regulations to this effect.

Incidentally, only harmless and certified coal-tar colors may be used, where their use is not otherwise illegal, in foods, and a system of certification for all such dyes has been established. Already lists of dyes suitable for use in foods as well as dyes suitable for drugs and cosmetics have been published. Artificial colors, artificial flavors, and permitted chemical preservatives are required to be so declared on the label.

When we come to the section of the Act which relates to drugs and therapeutic devices, we find here the one outstanding provision so far as public health and protection are concerned. I refer to Section 505, known as the New Drug Section. The Senate of the 75th Congress passed a resolution, No. 194, requesting information as to the cause of deaths attributed to the so-called Elixir of Sulfanilamide, and the report of the Secretary of Agriculture is incorporated in what is known as Senate Report No. 124. At the time this report was made, in November, 1937, 93 deaths traceable to the so-called Elixir of Sulfanilamide were reported by the Secretary of Agriculture, and, as history shows, this number was finally increased. Sulfanilamide itself had been acclaimed by members of the medical profession as a marvelous therapeutic agent in many severe manifestations of an infectious order. Much has been written of the therapy of this drug, as the pages of the *Journal of the American Medical Association* attest, coupled, however, with the editorial comment that caution should be exercised in its administration and that such administration should take place

only through competent physicians.

A firm of manufacturing chemists, having a request for this relatively insoluble drug in a liquid form discovered through their chemist that diethylene glycol was a solvent. The firm thereupon manufactured quantities of this so-called Elixir, really a solution, in diethylene glycol, of sulfanilamide, and put it on the market largely through physicians, although drug stores supplied consumers by over-the-counter sales with it. Early in October, 1937, the Food and Drug Administration received reports of deaths attributed to the administration of this drug in liquid form. Immediately investigators were dispatched to the scene of death, as well as direct to the manufacturing firm, and our inspectors found that this firm had actually put this drug on the market without experiments to determine its safety, in spite of the fact that prior to that time medical literature had emphasized the possibility of toxic symptoms of this glycol. The firm simply tested the product for flavor! While there were some sales of this drug over the counter to purchasers, most of them were through physicians direct, or on prescriptions.

Obviously, this statement should not be interpreted in any sense as a criticism of the medical profession on the ground of carelessness, since the practising physician, with the multitude of drugs which are placed on the market at his disposal, is wholly incapable of determining for himself the safety of products put out by firms which enjoy a reputation for dependability. Rather is the criticism to be placed upon failure of the public to protect itself through adequate legislation. Fortunately, this defect has been remedied, so far as is practicable, for when the Federal Food, Drug, and Cosmetic Act was passed in June, 1938, it not only contained a specific section relating to new drugs but designated this as

emergency legislation, effective at the time the signature was placed on the bill; this date was June 25, 1938.

To show how Congress has safeguarded the manufacture and shipment of new drugs, the law requires that in the case of a new drug, first an application must be filed with the Secretary of Agriculture, and it must contain full reports of all of the investigations which have been conducted to show the safety of such drug, there must be included a list of all of the components, the actual composition of the drug and the control exercised in the manufacturing, processing, and packing, and in addition samples of the drug and the complete labeling must be submitted. After sixty days an application is effective unless notice to the contrary issues. If the information is deemed insufficient and tests inadequate, the Secretary shall refuse the permit, or he may even revoke it after the permit becomes effective if subsequent tests show that the original tests were inadequate, or if the application contained false statements.

New drugs used solely for investigational purposes by experts who by training and experience are so qualified are exempted. By regulation, a drug is deemed to be new if any element of its composition is new, whether menstruum, excipient, carrier, coating, or other component, or a combination of two or more substances none of which is a new drug, or variation in the proportion of a substance even though that substance is not a new drug. Where the use of a drug, not in itself a new drug, for treating other symptoms than those for which the drug has been used is deemed a new drug, also a drug is "new" if the dosage, or method or duration of administration or application or other condition of use suggested in the labeling is changed, even though such drug is otherwise not a new drug. To show the significance of this sec-

tion, the Food and Drug Administration has to date on file more than 1,700 applications for new drugs.

Another important section of this new law is the one which relates to dangerous drugs, and which declares that a drug is deemed misbranded if it is dangerous to health when used in the dosage, or with the frequency or duration prescribed, recommended, or suggested, in the labeling. While the Act does not specify drugs which are dangerous, under this section the Food and Drug Administration, after the passage of the Act of 1938, issued specific notices to the effect that the department would regard cinchophen, neocinchophen, aminopyrine, sulfanilamide, and related substances, as coming within the ban of this section. These drugs have been designated as dangerous within the meaning of the Act because of the reports in the medical literature as to the untoward effect of their administration. There are others for which no similar notice has been or will issue. The responsibility in each case must rest upon the manufacturer.

Aminopyrine, as the medical profession knows, is capable of producing fatal agranulocytosis and this has been known for a number of years. Cinchophen and its derivative, neocinchophen, are definitely associated with acute atrophy of the liver. Sulfanilamide, with its known possible damaging effect on the blood cells, is definitely placed in the dangerous class. In fact, the Council on Pharmacy and Chemistry of the American Medical Association has warned against the indiscriminate use of this drug.

Another drug, which was the subject of publicity under the Act of 1906, is dinitrophenol, the reducing agent so often attended with tragic results. We have available reports of practically 100 cataracts as a result of the use of this drug. This also appears responsible for cases of agranulocytosis. As long ago

as 1933, the Council on Pharmacy and Chemistry, in the *Journal of the American Medical Association*, July 15, 1933, said "There are limitations to and possible dangers from the use of the drug clinically. It should be used only under strictly controlled conditions." In the same issue of that *Journal* is the following editorial comment: "Certainly for the present, at least, such investigations should be largely limited to controlled studies in hospitals by physicians competent in evaluating the effects of the drug, and with laboratory facilities capable of accurately determining blood, body tissue and other changes." It is worthy to note that at least one state has declared the sale of dinitrophenol as a drug under any condition to constitute a felony.

We may also take note that now the narcotic or hypnotic drugs which may be habit-forming are required not only to be named on the label but the text of the Act itself requires the notice "Warning—May be habit forming." Furthermore, products composed of two or more ingredients are required to show the name of each active ingredient, here again making it possible for those who elect self-medication to avoid those drugs to which there is a known idiosyncrasy. Last but not least the old joker with respect to therapeutic claims has been eliminated; no longer does the government have to show, frequently by expensive and time-consuming testimony, that the label of a worthless preparation is both false and fraudulent.

The cosmetic section is a new departure and the one significant clause in this part of the law is that which relates to dangerous cosmetics. Through the inevitable publicity which attended the passage of the new Act, the public became well acquainted with the tragedies laid at the door of paraphenylenediamine eyelash and eyebrow dyes. No longer may a cosmetic move

in interstate commerce which contains any ingredient which is dangerous when used according to the directions on the label, or when used in the customary or usual manner. Seizures were immediately effected of such dangerous cosmetics a few days after this section of the Act became effective in June, 1938. Some of the preparations which were indicted as causing tragedies are no longer obtainable. It is interesting in this connection to call attention to the fact that in the program for certification of coal-tar dyes, no coal-tar dye will be certified for use in the orbital area, or if a dye has been certified and is contained in a cosmetic, for example, recommended for use in the orbital area it will by regulation be

deemed to be an uncertified dye and its use prohibited.

In conclusion, it should be stated that this paper covers by no means all of the provisions which may have a bearing, perhaps indirectly, on public health and welfare, but merely recites the outstanding features from the public health standpoint of this Act of 1938. It is perhaps unfortunate that, with all the deaths and other tragedies attributed to drugs and to cosmetics, it took Congress 5 years to pass this Act, but fortunately it is passed, and even in its imperfect condition represents a substantial measure of protection to health for which the consumer of foods and the user of drugs and cosmetics should be devoutly thankful.

Aspects of Governmental Policy on Stream Pollution Abatement*

HERMAN G. BAITY, Sc.D., F.A.P.H.A.

*Professor of Sanitary Engineering, Division of Public Health,
University of North Carolina, Chapel Hill, N. C.*

ALL persons and agencies interested in the stream conservation problem are mutually agreed that there exists in this country a pollution situation that is most undesirable and uneconomic; that such conditions are so widespread as to constitute a major national concern; and that such remedial and preventive measures should be taken as to protect the public health, preserve public decency, conserve the wild life resources, and promote the use of natural waters for wholesome recreational purposes. It is ironical and unfortunate that some of these agencies, whose interests and objectives are common, should differ so widely and fight so bitterly over ways and means of accomplishing desirable ends. The greatest contribution that can be made to the cause would be the encouragement of a dispassionate consideration of the opposing points of view and a reconciliation of differences. During the recent session of Congress there have been evidences that feelings are running so high as to develop bitter prejudices, cause misrepresentations of facts, and encourage the widespread release of misleading propaganda. The proper legislative solution of this vexing problem, which requires the ultimate in vision and perspective,

should take place in an atmosphere that is clear and calm.

Before considering the opposing points of view or attempting to weigh existing differences, it would be well, perhaps, to reflect briefly upon the fundamental uses of streams and the general nature of the pollution problem.

THE NECESSARY USES OF STREAMS

The uses to which streams and other natural bodies of water are put are many and various, serving in as many ways the needs of our individual and national life. Due to geographical and topographical conditions, the river basin becomes a kind of closed community so far as water uses are concerned. The stream becomes the source for domestic and industrial water supply, irrigation and hydroelectric power developments; it serves the needs of recreational facilities; it provides the habitat for fish, shellfish, and water fowl; it furnishes the medium for water transportation; and provides the vehicle for the carrying away and ultimate disposal of the liquid wastes originating from our community life and industrial processes.

The use of a natural water course for the reception and disposal of liquid wastes is as necessary and legitimate as its use for any other purpose, subject to definite limitations. If such use renders the river unfit as the source of present or potential public water supplies,

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 18, 1939.

offends the senses, endangers health, inhibits the growth of wild life, prevents its use for recreation, or obstructs navigation, the development of the drainage area will, as a result, be hindered or even stopped, and all people and properties within the area will suffer. But in emphasizing this danger one must not overlook the possible economic consequences which would result if overzealous demands for a pristine degree of stream cleanliness required a degree of sewage and waste treatment that would be prohibitory to municipal and private enterprise.

The proper balance of stream uses is different for every stream, and for each, depending upon conditions, there is one combination which is most logical and economical. Such a policy does not mean that our water courses need become or remain open sewers. In every case public decency and economy demand a degree of cleanliness sufficient to avoid nuisance conditions, provide recreational facilities, support useful aquatic life, protect the public health, and preserve the natural beauties of water. The solution of the problem lies in true conservation, which implies the maximum possible judicious uses of the many properties of streams, such uses to be evaluated from a consideration of the broad demands of the public welfare. It does not lie in any simple statutory device which attempts to regulate water quality upon the basis of a single water use.

POLLUTION ABATEMENT A PECULIAR PROBLEM

A complicating factor in dealing with stream pollution is the fact that the municipal or private agency making an outlay of money for pollution abatement is not the one which benefits directly from the expenditure. It is the down-stream riparian owners and users of water who suffer from the pollution, or who reap the benefits of its abate-

ment. In an age of exploitation of natural resources this peculiar fact has, quite understandably, caused both public and private polluters of water to dump their wastes in the easiest and least expensive manner, leaving the unpleasant consequences to the users of water on the streams below. In the past they have too often ignored the public interest and the welfare of succeeding generations and have shunned the responsibility of providing pollution relief.

But the days of pioneer exploitation and the advancing frontier are gone. The growth of densely populated and highly industrialized areas has tremendously increased liquid pollution, while the rainfall has remained practically constant, and normal stream flow has actually diminished under the influences of modern land use. The resulting condition is not limited in its effects to esthetics, recreation, or public health; the economic consequences are being felt. Many industries requiring water of high quality for modern processes of manufacture are already suffering great losses by reason of its defilement by their own wastes, or those of sister industries.

It is high time that serious cognizance be taken of the condition and value of the nations streams, and plans laid for the sanitary redemption of some, and for the continued protection of others—plans not only for the present, but for the decades and centuries which are ahead.

EXTENT OF THE POLLUTION PROBLEM

The Third Report of the Special Advisory Committee on Water Pollution of the National Resources Committee, presented to Congress by President Roosevelt on February 15, 1939, contains the most accurate available data regarding the present status of the pollution problem. It estimates that 73,174,000 people of the United States

were served by public sewerage systems as of August, 1938, which represents 56 per cent of the 129,818,000 estimated population of the country at that time. This sewered population discharges daily approximately $5\frac{3}{4}$ billion gallons of liquid wastes, practically all of which finds its way, treated or untreated, into streams, lakes, and tidal estuaries. This enormous flow represents, however, less than $\frac{1}{2}$ per cent of the average daily flow of the streams of the country. The sewage from about 19,000,000 persons is subjected to primary treatment of sedimentation, while an additional 20,700,000 persons are tributary to secondary treatment plants. This total population of 39,700,000 served by some type of treatment works represents about 54 per cent of the sewered population, or approximately 31 per cent of the country's total population. In terms of volume, roughly $2\frac{1}{2}$ billion gallons of sewage are discharged daily in an untreated condition into water courses, while about $3\frac{1}{4}$ billion gallons per day receive treatment prior to discharge. However, it should be borne in mind that these statistics do not paint a true picture of the sewage pollution problem. The Special Advisory Committee is careful to point out that it is not essential that all sewage receive complete treatment and that, under certain conditions, no treatment may be necessary or desirable.

In the field of mining wastes, the committee estimates that annually about 2,700,000 tons of sulphuric acid entered streams as drainage from bituminous coal mines prior to the recent widespread campaign of sealing abandoned workings. From anthracite mining large quantities of culm and acid drainage also find their way into the water courses of this district. The oil fields are estimated to produce daily about 10 million barrels of brine, a considerable part of which drains into streams. In some sections of the country hy-

draulic mining operations continue to contribute materially to the silting of stream channels.

A great variety and volume of liquid wastes are discharged from industrial plants into the streams of the country. No reliable estimates are available as to their amounts, or their specific characteristics and effects, but the committee rated them in descending order of importance as follows: food products, paper and pulp, textiles, petroleum products, and metallurgical products. These wastes are harmful to the receiving streams in a number of ways. They may contain substances causing disease, they may impart obnoxious tastes, odors, and colors, which are revulsive to the senses, render the water unsuitable for industrial purposes, corrode structures, prevent recreational use of the stream, and inhibit the development of fish and other forms of wild life.

COST OF POLLUTION ABATEMENT

The Special Committee estimates that the further cost of treatment works to bring about a reasonable abatement of water pollution would involve an expenditure of approximately \$1,000,000,000 for municipal sewage treatment, about \$52,000,000 for the control of coal mine drainage, not less than \$100,000,000 for the treatment of oil field brine, and approximately \$900,000,000 for the treatment of industrial wastes for which practicable processes have been developed. The annual operating and maintenance costs for the new sewage treatment plants would amount to at least \$15,000,000, while the fixed and operating charges for the treatment of mining, oil field, and industrial wastes would probably exceed \$225,000,000 per year. These estimates of the committee for installation and operation assume that optimum use would be made of the natural purification capacities of streams and that, in many situations, much waste would be discharged untreated or

with only minor treatment. The complete treatment of all wastes is estimated to cost several times more than the programs outlined above. Such a degree of treatment is considered unattainable and, even though it were possible, a program of this extent is not considered necessary.

FEDERAL LEGISLATION

During the past 5 years various bills dealing with the problem of stream pollution have been introduced into Congress. These bills fall generally into two types, representing two opposing schools of thought with respect to regulation, and may be briefly summarized as follows:

The first measure dealing with pollution control was introduced into the 74th Congress by Senator Augustine Lonergan of Connecticut. Largely supported by the wild life conservation group, the Lonergan Bill provided for a central federal regulatory agency to exercise pollution control through injunction procedures in the United States courts.

At about the same time other bills were introduced into the Senate and the House providing for federal participation, through an existing agency, in a program of educational, research, and coordinating activities, but with regulatory control left to the states. These bills embodied the principles considered desirable by the health officials of the country, and were represented in the later Barkley-Vinson measures introduced in the Senate by Senator Barkley and in the House by Representative Vinson.

Neither the Lonergan nor the Barkley-Vinson type of bill received final action during the 74th Session, and both types reappeared during the 75th Session. Late in this session the Vinson Bill was passed by both houses after the elimination of the drastic regulatory provisions attached to it by amendment in the

Senate, and the U. S. Public Health Service was designated as the agency to represent the United States Government in the program. Quite surprisingly, the bill was given a pocket veto by the President on the basis of a technicality, although he voiced hearty approval of its basic objectives and principles.

The 76th Congress saw the early introduction in the House of bills similar to the Vinson Bill: HR 295 (Parsons), HR 922 (Spence), and HR 2890 (Bland). One similar to the Lonergan type, HR 4170, was introduced by Representative Mundt. Later in February, Representative Mansfield, Chairman of the Committee on Rivers and Harbors, introduced HR 4314, the bill suggested by the Advisory Committee on Water Pollution of the National Resources Committee as incorporating the best opinion of federal planning, budgetary, health, and conservation agencies, containing all the basic principles included in the original Vinson Bill, and meeting the technical objections upon which the Presidential veto had been based.

Meantime, Senator Barkley had submitted S-685, the same bill as the Vinson measure of the last session with some minor revisions to remedy partially the criticisms of the President, and Senator Clark had introduced S-1691, another measure similar to the Lonergan bill. The Barkley measure passed the Senate with minor amendments and went to the House, where it was reported favorably after being amended to conform to federal budgetary procedure. This bill was given clearance in preference to HR 6723, a revised bill later introduced by Mr. Mundt, but the adjournment of Congress left it in the category of unfinished business. It will doubtless come before the House for action at the next regular session.

CONFLICTING POINTS OF VIEW

In general, the organized wild-life conservation groups appear to believe

that the only effective machinery for pollution control is a central federal agency vested with broad and arbitrary powers to enforce abatement orders by mandamus procedures in the federal courts. They select the U. S. War Department as best qualified to administer the program. They profess a lack of confidence in the ability of state and local governments to enact adequate and uniform laws for the abatement of pollution or to enforce such laws even though they were on the statute books. Furthermore, they charge federal and state public health agencies with an unsympathetic attitude toward pollution abatement, disparage the achievements of these organizations in preventing and relieving pollution, discount the value and applicability of their research developments, and actually accuse these public agencies of bad faith in dealing collusively with offending industry.

On the other hand, all of the public health agencies of the country, all federal bureaus and departments concerned with water quality and use, such planning agencies as the National Resources Planning Board, and the President of the United States, apparently favor a type of legislation which gives to the U. S. Public Health Service certain functions and responsibilities pertaining to research, education, stimulation, and coördination, but leaves to the states, or authorized interstate agencies, the powers of regulation and control.

Those who have had most experience with problems of this nature subscribe to this latter policy as being most logical, reasonable, and, in the long run, most productive of satisfying results. Although the advocates of rigid federal regulation may not be entirely without justification for their impatience with existing conditions and their cynicism with respect to the future effectiveness of state control, it is believed they may be laboring under certain illusions in their active legislative campaign.

Admitting the possibility that any commentator on so controversial a subject may have predilections that sway him from a course of strict neutrality, the writer ventures to examine a few of the points at issue between the two schools of thought:

Federal vs. State Powers—The power delegated to Congress by the commerce clause of the Constitution is limited to commerce between the several states. Under this authority the federal government now exercises control over the discharge of refuse matters, other than liquid wastes, into navigable waters, and the Oil Pollution Act of 1924 rests upon this clause for its constitutionality. The same justification might apply to pollution of navigable streams by domestic or industrial wastes where such discharge constituted actual and appreciable hindrances to navigation, such, for example, as sludge banks in ship channels. However, isolated cases of this kind would not appear to authorize the taking over of the entire field of pollution control by a federal agency. Since international treaties become the supreme law of the land, without question of constitutionality, the Congress has power to control pollution in so far as necessary to fulfil treaty obligations relating to boundary waters, regardless of whether such streams are navigable or intrastate in character. The federal government has the power to regulate pollution on the public domain and exercises some indirect control over water quality through the "beneficial public uses" clause of the Federal Power Act. Its domestic quarantine powers give it authority to approve the safety of water used for drinking and culinary purposes on interstate carriers, and, under voluntary agreements with the various states, it enforces regulations regarding the certification of interstate shipments of shellfish. Aside from these limited powers, in the opinion of leading authorities, there appears to be no con-

stitutional authority for federal water pollution control.

The authority of the states over such intrastate matters as stream pollution is well established, and cannot be taken away. State legislatures, by exercise of the police power, may enact statutes relating to pollution control or may delegate to agencies of the state the authority to formulate and enforce regulations pertaining thereto. However, the federal government does have the authority to conduct scientific and technical investigations relating to water pollution, to coöperate with the states in an advisory capacity, and to render financial assistance to state and local authorities for investigative and construction purposes. There is strong opinion that, regardless of legal powers, this indirect type of participation by federal agencies would result in a more effective and orderly program of pollution abatement than could possibly be achieved by federal domination.

Efficacy of Centralized Control—It is only natural that those observing the sad plight of prostituted streams should infer that the trouble lies in the inefficacy of control machinery under our system of federal and state division of responsibility. There comes the urge to scrap the machinery and build on a different design. It appears doubtful that our state-federal form of government is responsible in any large measure for the present situation. The pollution problem is old and world-wide, and for almost a century the countries of Europe have been wrestling with the legislative and administrative phases of pollution abatement. No nation has yet developed a workable plan for reconciling satisfactorily the various conflicting interests in natural waters to provide maximum judicious use for the greatest public benefit. It appears that the record in small highly federalized countries is no better than in those where the legislative and en-

forcement responsibilities are dispersed.

The explanation of the condition lies not so much in the deficiency or obsolescence of control machinery as in the extreme complexity of the problem, the multiplicity and conflict of interests, and the fact that pollution is only one phase of the larger problems of the conservation and maximum advantageous use of our water resources in general. A change in this condition will not result spontaneously from any device of centralizing power and responsibility. It may be expected to come gradually from the extension of powers on all levels of government, by fitting pollution control into its proper place in the broader control program of planned conservation and use of all water resources, by constant educational and promotional work of all interstate agencies, by relentless attacks along the whole front of the water problem by local governments under the guidance, stimulation, and participation of federal groups, by the promulgation of interstate compacts and agreements, and by financial assistance from the federal government to public and private polluters requiring such aid.

Enforcement by Mandate—To the provoked and impatient the correction of public evils by mandate has the appeal of being quick and effective. Regulation appears on the surface to be a simple device for curing all ills. Critics proclaim: "There ought to be a law." Perhaps it would be well to remember other times in our national life when similar evils have been observed, and when the laws designed to provide the perfect panacea proved to be unenforceable and disappointing. Moreover, those who have had occasion to invoke the police power of government in dealing with the public have long ago learned that the mailed fist is less productive than the velvet glove. Public psychology reacts adversely to arbitrary force. Persuasion, education,

and coöperation are more effective instruments than the "big stick," and the power of law should be held in reserve for exercise only when milder measures fail. The Lonergan, Clark, and Mundt types of legislation provide for actions in equity to be brought in the federal courts and instruct United States attorneys to institute such actions when requested to do so by the Secretary of War or any one of the district boards. These bills appear to remove all existing authority of the states over sewage and waste treatment plants and place their operation directly under the supervision of the Chief of Engineers, except for those waters ruled not to be navigable.

Although these bills carry provisions for coöperation with state agencies, for advisory services of other federal agencies, for the collection and dissemination of information, and for federal financial assistance, it is feared by many that the emphasis upon drastic control by court action would result in inadequate investigations of actual stream requirements and of the economy and applicability of treatment processes. Precipitate action without complete information would result not only in mental anguish but in the gross waste of public and private funds. Enforcement of the provisions of these measures with respect to new or additional pollution would tend to hinder industrial development and municipal growth, and might preclude the extension of sewers to presently unsewered and insanitary communities. In any case, such measures would be concerned with pollution alone and would neglect consideration of the many other related and inseparable problems of water conservation and use.

Pollution Primarily a Health Problem

—There can be no doubt that among the many objectionable and hazardous effects of water pollution the interests of the public health are paramount. Even the most ardent angler must recog-

nize that, in the general economy of a stream system, the uses of water for such vital needs of life and health as public water supply and the ultimate disposal of domestic wastes are of supreme significance. And when the health interests in a stream are adequately safeguarded there is usually the consequence that the quality standards of water for other uses are automatically met. It is therefore only reasonable and proper that the administrative responsibility for pollution control should be vested in federal, state, and local health agencies.

In their criticism of the Barkley-Mansfield type of bill, sponsors of the Mundt legislation disparage the splendid research accomplishments of the U. S. Public Health Service in this field and charge health agencies in general with indifference, inefficiency, and bad faith in dealing with water pollution. The charge has been made repeatedly that health organizations are in league with industrial polluters in conducting "study clubs" for the indefinite and wilful delay of corrective measures. All who are acquainted with the records of the U. S. Public Health Service and state health departments will recognize such statements as false and libelous. There is probably no organization in the world that has excelled the record of the U. S. Public Health Service in the development of fundamental knowledge in the realm of stream pollution, water and sewage treatment during its 26 years of intensive and basic research on these subjects. The critics appear to be so unacquainted with the technical bases of pollution abatement as to fail even to recognize that the scientific problems are difficult, complex, and slow of solution. They remind the writer of an impatient textile executive who said that he could take a good chemist and solve all the waste treatment problems in his industry in 30 minutes.

Army Engineers or Public Health

Service—Sponsors of the Mundt and Clark Bills insist that federal control be vested in the War Department in the interest of rigid enforcement, and cite many other reasons why the Army engineers should be placed in charge of the program. Without disparagement of the splendid record of the Corps of Engineers in their field of responsibility, it can be stated that not one of these reasons is valid. It is notable that there is missing from this list of reasons the primary one which should govern the selection of any federal agency to perform a particular task, namely, the availability of personnel having the viewpoint, training, experience, background, and technical equipment to handle the problem. These resources for pollution control have been built up by the U. S. Public Health Service over a period of more than 25 years, during which time, with meager appropriations, they have assembled a highly qualified organization and established an enviable record of useful accomplishment. This work has been quiet, largely intangible, and removed from public view—a reason, perhaps, why the tangible and costly construction projects of the Corps of Engineers should give some people the idea that this agency is vastly superior in its ability to get things done.

As a matter of fact, in all stream investigations in which the Corps of Engineers and the U. S. Public Health Service have participated jointly, the Corps has requested the Health Service to handle all phases of the work pertaining to pollution, stream quality, and abatement recommendations. It is presumed that this has been done because they feel that the Health Service is much better equipped to do the job. In any type of program the Army engineers would continue to handle matters relating to hydrology, maps, channel structures, channel configurations, etc., but it is certain that they would be the last to claim their superior qualifications

to deal with the complex problems of pollution. It is apparent that the real reason for the opposition to the U. S. Public Health Service is the fact that this agency does not subscribe to the extreme views of a few groups interested in only one phase of the problem. Through more than 50 years' fruitful participation with states in regulatory measures for the improvement of the public health and welfare, the U. S. Public Health Service has gained the full faith and confidence of the people of the nation. It is logical and expedient that it should represent the federal interests in any pollution abatement program.

Progress in Pollution Abatement—Advocates of the plan of rigid federalized control-by-injunction maintain that the streams of the country are in such appalling condition as to constitute a threat to civilization, and are becoming progressively worse, as a result of the inherent impotency of any state system of regulation and the utter indifference and ineffectiveness of local enforcement agencies. In this connection it is enlightening to look at the record.

According to the report of the Special Committee on Water Pollution, more progress has been made in municipal pollution abatement during the past 6 years than in the preceding quarter of a century. Since 1932 the population tributary to treatment plants has increased from 21,500,000 to 39,760,000, a change from 35 to 54 per cent of the sewered population of the country, or an increase from 17 to 31 per cent of the nation's total population. Within this period, and in the face of a rapidly increasing population and tremendous extension of sewer service, the sewered population not served by sewage treatment plants has been reduced from 40,500,000 to 33,414,000. This has been accomplished at a cost approaching one billion dollars.

In the State of Ohio, for example,

during the 12 year period, 1928 to 1939 inclusive, 160 municipalities have constructed sewage treatment improvements costing about \$40,000,000 (exclusive of costs for collecting sewers, interceptors, etc.,) serving 3,223,000 people, or nearly 50 per cent of the state's population. In the State of New York, between 1933 and 1939, 102 municipal sewage treatment works have been built at a cost of more than \$38,000,000, and serving 2,854,000 persons. Together with the 161 plants installed in the preceding 30 years, these works now treat the sewage of 263 cities and towns, representing a population of 5,400,000 people, or 78 per cent of the entire sewered population of the state. New York City's 10 year program for cleaning up the pollution of that area at a total cost of about \$150,000,000 is proceeding on schedule, and several large plants have been placed in operation. The great abatement program of Chicago is essentially finished, and those of other large centers of population and industry are proceeding apace. Proportionate progress is being made in other regions of the country.

While an important impetus to this recent progress may be attributed to the availability of federal grants-in-aid, most of the credit should probably go to the behind-scenes educational and promotional activities of public health agencies which have been relentlessly carried on. And another important reason for progress lies in the realization by municipalities and industries of their moral and legal responsibilities in pollution abatement. While the progress made in the treatment of industrial wastes has not been so outstanding as that in the municipal field, many new plants have been constructed, and the general indifference of industry is noted to be rapidly disappearing.

The Federal-State Pattern of Cooperation—During a period of about 50 years, there has been developed a plan of action and coöperation between

federal and state authorities on all matters pertaining to the public health that has effected a closely-linked relationship and results of most satisfying and significant values. In essence the plan involves the provision by the U. S. Public Health Service of (a) research services to develop scientific facts and procedures, (b) safe and uniform standards, (c) guidance in methods and procedures, by expert technical assistance, and (d) financial assistance; while the responsibility for legislation and administration of the programs is left with state health agencies. Notable among the achievements in the sanitary field of this working arrangement have been: the improvement of drinking water quality, with consequent decrease of the intestinal diseases, through the application of the Treasury Standard; the successful attack on the malaria menace of the South through the use of scientific facts, methods and procedures developed by the Public Health Service; the unprecedented advance in safe milk production through the adoption of the U. S. P. H. S. Standard Milk Ordinance; and the protection against infected shellfish by the application of standards pertaining to sources, production, and marketing. In all of these activities, and many others, the U. S. Public Health Service has developed the scientific facts and shown the way; the states have accepted guidance and executed programs with enthusiasm and efficiency. There is every reason to believe that this plan is the best one that can be conceived for dealing with the problem of stream pollution abatement.

CONCLUSIONS

The foregoing discussion indicates the author's belief in the following principles relating to the administration of a national program of pollution abatement:

1. That a stream must be recognized as supplying various important needs within the drainage basin, and that all these uses must be considered and balanced.

2. That one of the natural and inescapable uses of streams is for the reception and ultimate disposal of liquid wastes produced on their watersheds, after such treatment as may be required.

3. That the self-purification capacities of streams must be utilized to a greater or less degree in all cases, alone or as an adjunct to treatment processes, and that complete treatment of all wastes is neither economically possible nor scientifically necessary.

4. That control of pollution by the injunction process, administered by a federal agency, is of doubtful constitutionality, contrary to the principles of democratic government, wasteful of money and ineffective in its prospect of satisfying results.

5. That regulation of pollution is a proper function of state government, and that a federal agency should operate in an investigative, stimulative, and coordinating capacity, with financial aid furnished for administrative and construction purposes.

6. That the vexatious problems of pollution in interstate waters can best be solved by an extension of the system of interstate compacts and agreements.

7. That the most important factors in pollution abatement are those related to public health, and that health agencies should have the responsibility of administering the program.

8. That the U. S. Public Health Service is best qualified to represent the interests of the federal government, and that the pollution abatement program should be conducted

in coöperation with state health agencies along the lines of the "Federal-State Pattern" which has been found so effective in other similar undertakings.

9. That with a national campaign conducted under such a plan, and with reasonable availability of federal funds for loans and grants-in-aid, the future progress in pollution abatement should be comparable with that of the past 6 years. At this rate, within a period of 5 to 10 years the more objectionable conditions of sewage and industrial waste pollution should be corrected.

DATA CONDENSED FROM THIRD REPORT OF SPECIAL ADVISORY COMMITTEE ON WATER POLLUTION OF NATIONAL RESOURCES COMMITTEE, HOUSE DOCUMENT NO. 155, 76TH CONGRESS, 1ST SESSION, 1939

I. STATUS OF WATER POLLUTION IN UNITED STATES, 1938

1. *Municipal Sewage:*

Total Population of United States	129,818,000
Urban Population (Incorporated Places in Excess of 2,500)	73,200,000
Served by Public Sewers	73,174,000
Per cent of Total Population Served by Sewers	56
Population Tributary to Primary Sewage Treatment Plants	19,000,000
Population Tributary to Secondary Sewage Treatment Plants	20,700,000
Total Population Served by Sewage Treatment Works	39,700,000
Per cent Sewered Population Served by Treatment Works	54
Per cent Total Population Served by Treatment Works	31
Daily Discharge of Untreated Sewage, gallons	2,500,000,000
Daily Discharge of Treated Sewage, gallons	3,250,000,000

(NOTE: These statistics cannot give accurate representation of pollution problem. It is not essential that all sewage receive complete treatment and, under certain conditions, no treatment may be required. The reasonable self-purification capacities of streams should be utilized.)

2. *Mining and Industrial Wastes:*

Acid Mine Drainage from Bituminous Coal Fields, tons H_2SO_4 /year	2,700,000
Culm and Acid Drainage from Anthracite Coal Fields	Unknown Amount
Brine from Oil Fields, barrels per day	10,000,000
Debris and Silt from Hydraulic Mining Operations	Unknown Amount
Industrial Waste from Manufacturing Processes	Unknown Amount

(NOTE: Waste-producing industries account for about 75 per cent of manufacturing activity of U. S., with an annual value of production of 18 billion dollars and with an employment of about 3 million persons.)

II. ESTIMATED COST OF POLLUTION ABATEMENT

1. *Municipal Sewage:*

Cost of Additional Sewage Treatment Plans	\$1,141,000,000
Annual Operating Costs of Additional Treatment Plants	15,000,000

(NOTE: These estimates based upon degree of treatment considered necessary and reasonable. If complete treatment were applied, additional capital cost would be about \$2,000,000,000 and annual operating cost about \$30,000,000.)

2. *Mining and Industrial Wastes:*

Cost of Acid Control at Abandoned Bituminous Coal Mines	\$ 12,000,000
Cost of Corrective Treatment at Anthracite Coal Mines	40,000,000
Cost of Treatment Plants for Oil Field Brines	100,000,000
Cost of Industrial Waste Treatment Works	900,000,000

Total Capital Costs	\$1,052,000,000
Annual Costs of Mining and Industrial Waste Treatment	225,000,000

(NOTE: These estimates do not contemplate complete treatment of all wastes, but assume optimum use of natural purification capacities of streams.)

3. *Recapitulation:*

Capital Cost of Necessary Treatment Works	\$2,193,000,000
Annual Operating and Maintenance Costs	240,000,000

III. PROGRESS IN POLLUTION ABATEMENT IN UNITED STATES

Year	Sewered Population	Tributary to Treatment Works	Population Tributary to Treatment Works	
			Per cent of Sewered Pop.	Per cent Total Pop.
1904	28,000,000	1,100,000	3	1.2 (approx.)
1910	34,700,000	3,900,000	11	4
1932	62,000,000	21,500,000	35	17
1938	73,174,000	39,700,000	54	31

Some Essentials in Training for Public Health*

ALAN GREGG, M.D.

*Director for the Medical Sciences, Rockefeller Foundation,
New York, N. Y.*

THE task of arranging and effecting adequate training for public health officers is a duty for which we are likely to be held answerable by a mystified and impatient public for some years to come. Until every state is able to provide from its native sons and daughters its future health officers and personnel, to train them, and to give adequate employment to most if not all so trained, we may confidently expect much more than local interest in the performance of our schools or courses of training for public health work.

Outsiders interested in the performance of a school are not likely, however, to take a sentimental or overly sympathetic attitude toward the discrepancies between results sought and results obtained. State governments seeking competent health officers are not well impressed by excuses. Forceful needs do not adjust their demands to the limitations imposed upon a school of public health by insufficient personnel, inadequate income, personal jealousies, or lack of administrative foresight. Outsiders looking for competent health

officers are impatient of those deformities and inadequacies in a school which we may explain as "due to historical development." To put it in other words, any course or school for the training of public health officers is certain to live during the next 20 years in an atmosphere of lively criticism—at times vague, unreasonable, and unsympathetic; at times accurate and merciless; but nearly always inescapable—in fact, healthy and stimulating by virtue of its appreciation of positive performance and its disinterest in explanations.

So great is the likelihood of our being held responsible for a better performance than is likely to occur in a climate of inadvertence or of unreflecting faith (alternating with self pity), that it could be useful to give our attention to this query: What are the simple essentials of education for public health?

I take it that the elements of an educational process are simple and straightforward. They are to be found in the nature of the students, in the nature of the teachers, and in the character of the contact between students and teachers. Time will not permit detailed and properly qualified statements on each of these factors. It must suffice to make a few comments

* Read at the General Session on Professional Education of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 18, 1939.

upon the more important aspects of each.

The nature of the students resolves itself into their innate or natural abilities, their motivation and their previous training. In each of these qualifications we are dealing with what comes to us in large measure already formed, and therefore our most immediate task is largely that of selection.

As for the point of natural ability, I wish that the standard of performance in the course of preventive medicine in every medical school were as severe, rigorous, and important a criterion of a student's character and claim to a degree as any course in the school. And I wish that the schools of public health rejected a larger percentage of applicants and failed say 20 per cent to 40 per cent before graduation. For let us not forget that every incompetent we release into the field of public health discourages 5 to 50 better men by his colorless example and later may also obstruct the recognition and promotion of competent juniors from an all too justified feeling of his own insecurity.

As regards the motivation and sympathies of the students I have come to be a blunt heretic. A friend of mine conversing some years ago with King Albert of Belgium heard with some surprise the King say "A government which holds its chief concern to be the welfare of the people is a good government whether its form be Communist, Fascist, or Democratic, and a government which neglects the welfare of the people, whether it be Democratic, Fascist, or Communist is a bad government."

I believe that single-minded, simple, and direct concern for the welfare of the people is, as a motive in American medical schools for the guidance and stimulation of students, in part neglected and in part eclipsed by preoccupation with the demands of technic and science, and both to the

detriment of the public health of our nation. Furthermore I believe that among first year students there is scattered more potential concern for public health and public welfare than is to be found in their fourth year. Until we cease ignoring the validity of sociology, psychology, anthropology, economics, government, and even comparative religion as subjects for student concern, we shall remain responsible for reducing the valences of the profession, and reducing instead of expanding the variety and excellence of the physician's capacities to combine with the public for the common welfare.

It is already clear that the present expense of a medical education has begun to affect the selection of medical students and to show not only in the predominantly upper middle class origin of medical students, but also in the predilection for the lucrative forms of practice on the part of those who may have been obliged to borrow the funds for their education. I raise serious question as to whether substantial scholarships in the schools of public health would not valuably counteract the selection which now is in force. We might reflect upon the form of appointment to the free education at Annapolis and West Point for comparison. How can we expect understanding of the underprivileged to emerge strong and tenacious and self-respecting among students who have never been underprivileged? We may expect a student to have sympathy of a sentimental sort—but not the simplicity and conviction of understanding born of experience.

The previous training of the student coming to the medical school has often more than enough of chemistry, usually enough physics and biology, but not enough mathematics, sociology, psychology, anthropology, economics, and English for his needs as a public health officer. The previous training of an

entrant to a school of public health is usually defective by reason of the status accorded to public health in his medical school. It is often then too late to change the system of values he has picked up.

I see some real advantage in assuming without rancor or recrimination that a medical course centered upon the training of men to cure illness for fees will not be naturally inclined to provide time or an adequate point of view for training men for quite a different purpose, the prevention of disease as a public salaried servant in an environment where statesmanship, social sympathy, and educational skill are also paramount qualifications. I see particular advantage in assuming that our present medical education suffers from the defects of its qualities. Such an assumption leads to the realization that improving the medical school courses in public health and preventive medicine is the decisive opportunity we have under the existing circumstances to improve recruitment and eventual performance of public health personnel.

The second element of the educational process I hold to be the nature of the teachers of public health. There again as with the students we must consider their capacities, their interests, and their training or experience. During the next 20 years we shall apply the existing practices in the selection of teaching personnel in medical schools and schools of public health, or we shall devise new forms of selecting our teachers. I hope that the criteria for professional appointment and promotion will be first: *Has he added to the knowledge in his field?* second: *Does he teach out of stimulating experience?* and third: *Is he locally convenient, congenial, coöperative, inexpensive, et cetera?* And I hope the qualifications in capacity and maturity and experience of every possible *candidate* for major teaching appointments will be a

matter of wide discussion and continual investigation throughout this country so that university committees or deans charged with finding the best man available will be rewarded and not disappointed or disillusioned by extramural search and consultation.

For the training of teachers of public health in medical schools and schools of public health the preparation should be both long and broad—probably more intensive for the special men in the schools of public health and more varied and even longer for the men going into the medical schools as professors of the subject there. In order to offer adequate experience as well as a sufficient time in prearranged training, departments should have 2 to 5 positions subordinate to the full professorship and should detail their men for periods of work in city, county, state, and federal positions which give crude, direct, and realistic experience in field work. We have not yet solved the riddles of the best relation between laboratory and field work, between theory and practice, but we would be wise to explore further and report to each other our findings in this important field for discovery. I should consider interchange of junior personnel with active field units as well as with other university departments to be of the greatest value in building up the ranks from whom the future professoriate may be chosen.

The third element of educational success was noted as being the conditions under which students and teachers come together and work. This also is hard to dispose of as briefly as the limits of this talk require. I have preferred to describe as essential the conditions under which students and teachers come together and work since the finest and most valuable educational experience escapes the terminology of curriculum makers and devisers of degrees. But so serious

has grown the multiplication of degrees in the field of public health that a few comments present themselves on the subject of degrees, diplomas, certificates and the like, inadequate as they are to describe the conditions under which teacher and pupil are supposed to have met and worked together.

I take it that the purposes of a school in giving a degree or certificate are neither single nor simple. In some ways degrees are like paper money, a system of tokens, promises, or equivalents, as good and as variable as the resources of the issuing agencies. They are not the solid metal of ability or maturity. That metal is always in demand. They follow Gresham's law, and, like all tokens, are subject to counterfeit. Of course degrees serve intramural purposes in acting as a framework for courses and plans of work. They also serve as an attraction and reward for student performance. Sometimes they may be hardly more than the *quid pro quo* exchanged for conscientious attendance and the payment of tuition fees. But nonetheless they have quotation in the world outside. And then the trouble begins. Is the D.P.H. of the University of Balacava as good as the C.P.H. from Karshish College? Why? What does a Diploma in Public Health mean? If the D of M.D. means Doctor how is the public to be expected to know that the D in D.P.H. mean Diploma? Do not doctors get diplomas when they graduate? May D stand for deception? And certificates in public health—do they assure a knowledge of statistics or guarantee an ignorance of medicine? Always? Sometimes? Or never? Does the Dr.P.H. really exclude the possibility of flagrant incompetence or is it sometimes rather a proof of some exceptional special ability? Can we deny the confusion there is to laymen in such a mixture of certificates and diplomas among bachelors, masters, doctors, and

doctors who are not what the layman calls doctors at all? Without deceiving ourselves at all we shall manage to mislead the public as the initial step in serving them. We cannot just assume that the triumphs of preventive medicine are so great as easily to survive the ludicrous spectacle we present of 13 different degrees in public health given by 10 different institutions in the United States.

Something far simpler is needed by the public we want to work with. Let us start our service by being simply understood in the estimates we make of our pupils' qualifications. What are the essential needs? What would the public understand?

The individual not possessing a medical degree who spends at least a full year in public health courses designed for his or her level of training, and who passes appropriate tests, practical as well as oral and written, should be given a certificate or master's degree in public health. I do not believe in any title for studies over a shorter period than a year. Why should we underwrite inadequacy?

The degree of Doctor of Public Health should be confined to persons already possessing the M.D. and should be so planned and so awarded as to constitute a guarantee of competence to undertake the duties of health officer in city, county, state, and federal health services. It should involve field experience as well as university instruction and be an assurance comparable to and perhaps better than that given by the specialty boards now and in the future in other fields of medicine.

In all matters of licensure, certification, and degree giving, it is remarkable to see how common is the confusion between what is intended to give protection to the public and what is intended to give distinction to the individual. Both types of denomination have very great value to science and to

society at large. But it is the hallmark of educational stupidity to withhold distinction from the onesided specialist or to imply all around competence where it does not exist. Both kinds of degrees should be rigorous if they are to convey an honorable status to the recipient. The difference between what I call distinction and all around competence lies in the measure of responsibility the recipient may be expected successfully to assume for the manifold and variant duties of a health officer. I should like to see the C.P.H. or M.P.H. and the Doctorate of Public Health and only these, as rigorous guarantees of measured and certain degrees of competence. For distinction, however, as a specialist or contributor to knowledge in some special field, it would be valuable to have the Doctor of Science in Public Health. Then the public could begin to know where we are and what to look for as qualifications.

As a degree of special distinction and difficulty the Doctor of Science in Public Health could be honestly given in a few medical schools and the schools of public health. It would be of use in training and denomination of candidates for professorships and positions in research laboratories. It should be neither common nor easily obtained and thus become a mark of acknowledged competence in research and scholarly attainment.

This is all the public can both under-

stand and respect. For in the oncoming realities of public health, what will make the difference is the lay and professional opinion held of teachers and practitioners of preventive medicine and public health—of their native ability, of their characters, and of the excellence of their training or the breadth of their experience. Let us see to it that our degrees exactly reflect such opinions.

We need not go beyond that. I am not concerned here with "credit hours" nor the itemized content of the curricula. What seems important to me I have mentioned—that we pay attention to the capacities, motives, sympathies, and previous training of our students; that at present we accept fewer candidates for degrees because we know that quality attracts quality and imitations will discredit us and ruin the status of our degrees; that we give the most serious attention to the preparation of future teachers, especially in the medical schools; that we realize that degrees have meaning outside as well as inside the institution and that they are only valid when they are understood, and valuable as long as they stand sincerely for the things of real value—capacity, sympathy, and experience. And above all let us seek for simplicity, thoroughness, and realism in the service we offer to the public in teaching its servants a kind of medicine still new and still under-rated.

The Trained Worker Goes to Work*

W. P. SHEPARD, M.D., F.A.P.H.A.

Assistant Secretary and Pacific Coast Welfare Director, Metropolitan Life Insurance Company, San Francisco, Calif.

IT has been my privilege for some years to be associated with both the producing and the consuming ends of public health work. I have been a city health officer and have done part-time public health teaching both to medical students and health officer trainees. My present work brings me in close touch with public health officials, especially in the western states. The following observations are entirely empirical, but are based upon experience and sympathetic analysis.

First, it must be said that the presence of trained young men in the field is rapidly changing the whole public health picture. It reverses the vicious cycle which has hindered us so long; that is, health officer incompetence, insecure tenure, inadequate appropriations, lack of results, still less adequate appropriations, greater incompetence, less secure tenure. Many have felt that this cycle could best be broken by increasing the competence of the health officer, since this will generally improve results and thus lead to increased appropriations and improved tenure. These more competent young health officers are reversing the process described by Dr. Gregg by *encouraging* "five to fifty better men" to enter the field, and by *accelerating* the "recognition and promotion of competent

juniors." They are also improving the status of our profession in relation to other professions, especially practising physicians, teachers, and statesmen.

It is a pleasure to report that these young men are generally well trained in the scientific aspects of their work. They have learned remarkably well what public health stands for and what it aims to do. They show a surprising ability to apply their clinical experience to public health work and to think of the health of the group rather than of individuals. This is a great tribute to their teachers.

NEW HEALTH OFFICERS' PROBLEMS

Their problems are largely those of application. They know pretty well what to do, but not always how to do it. Hence, their major problems lie outside the field of their scientific training. These problems may be classified under four headings: statesmanship, education of the public, administrative, and personal. Their professional public health problems are less troublesome, less time-consuming, and less menacing than these.

Statesmanship—A surprising number of problems have to do with statesmanship. These include such matters as health officer relationships with superiors and colleagues in the local governmental unit, with medical societies, other organized groups, and with people generally. Analysis of mistakes made in handling these problems

* Read at a General Session on Professional Education of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 18, 1939.

usually discloses lack of understanding of individuals or groups, often a lack of tolerance for those holding divergent views, sometimes unwitting or injudicious involvement with entangling alliances.

Professor Terman,¹ who has followed a group of gifted children for more than 20 years, concludes that given superior intelligence, "then the social factors and ambition, drive, and emotional balance are the main determiners of success and failure." In other words, the ability to work with people is important, in addition to intelligence. Whether we can teach the technics of working with people may be open to question, but it is a quality which should be a prerequisite to a health officership.

Ability to work with people is but a part, though an important part, of health officer competence. One health officer, now gone, lacking both competence and appropriation, took me to a meeting of his appropriating body. He was greeted by the chairman, saying, "Hello, Doc, what can we turn you down on today?" followed by three defiant, long-distance shots at the cuspidor by other members of the board. He did not get what he asked for. Another health officer of my acquaintance, known nationally for his competence and achievement, and, incidentally, lacking any academic public health degree, has had to explain to his appropriating body more than once why he considers it unwise for them to increase his salary. What is our training doing to increase the number of health officers like the latter and decrease the number like the former?

Is it possible that the public health professor's own secure tenure gives him a fine disdain for what he calls politics?² Is this disdain unconsciously transmitted to the student with the result that the ability to work with people is undeveloped and his competence thus hampered?

Two-thirds of the name "public health officer" consists of "public officer." Perhaps two-thirds of his duties consist of being a "public officer." But more than two-thirds of his training is on "health," a third of his title and perhaps only a third of his duties.

Education of the Public—Educational problems are often unrecognized as such by the recently trained health officer, but they exist in profusion. What appears to be lack of public support is often an educational problem of the first magnitude. The task of presenting health department objectives and needs convincingly at all times is largely an educational process. Leading the public to better health habits, improved health attitudes, enlightened health knowledge, and improved health behavior, all require educational ability. To do these successfully, the health officer, like the educator, must:

1. Determine, and limit himself to the hearers' ability to understand.
2. Adhere to simplicity for each level of understanding.
3. Remember that his criterion of success is the extent to which his presentation changes the recipients' choices, actions, and attitudes, not the effectiveness with which the known body of knowledge is summarized.
4. Aim for a lag between stimulus and response so that the response becomes a conscious, intelligent control over conduct, instead of being instinctive or habitual.
5. Start with the intellectual approach, devoid of emotion, in order to avoid emotional fixation. Emotional fixation is the method of dictators. Rather than being educational, it blocks further education.³

These are well recognized procedures in the teaching profession.

Educators have made great advances in understanding the learning process. They analyze and avoid the subversive forms of propaganda. They recognize that experience is the only real teacher. It is the aim of education to use the learner's own experiences to produce education. These are principles in-

herent in the educational process, regardless of the learner's age. They apply not only to school children but to adults as well. That the health officer needs these principles is apparent when we observe the sins committed by many in the name of health education. Among these are:

1. Evangelism, or direct emotional appeal. This is often effective to attain immediate ends, but it is far from education.⁴

2. Oracularity, in which the health officer, like many other physicians, seems to have an insatiable craving to tell others of his superior knowledge. This has led to the slang defensive phrase of youth, "Are you telling me?" Many dislike to be "told." When they are told, it seldom influences their choices, actions, and attitudes; hence, it is not education.

3. "Talking down" to groups. This is invariably distasteful and not education.

4. Talking over the heads of groups. This sometimes leads to desired results, but is bad manners and not education. When it leads to results, it is because the listeners believe in the sincerity of the speaker, not in what he says.

5. Failure to use health service as an educational instrument. Every service rendered by a health department has potential educational value, but it becomes educational only by the deliberate planning of those in charge. A health department vaccination clinic may result in many protected people, but it has educated its patrons only if they are thenceforth more prone to seek and obtain vaccination of their own volition.⁵

Medical schools have been slow to adopt the technics of modern education. Will public health schools do likewise?

Administrative—Administrative problems, though less frequent than political and educational, are often unrecognized or badly handled. No full-time health officer works without subordinates, and the further up the ladder he goes the more personnel he has to handle. Industrial relations or personnel management is no longer a rule-of-thumb procedure. The health officer is entitled to something more than learning by chance or by example (which may be bad as often as good) what is

commonly accepted as good management.

Good business sense is often lacking in health officers. Appropriating bodies are prone to consider the young health officer an earnest, agreeable fellow, but "no business-man." Some knowledge of bookkeeping methods, of cost accounting, taxation and public revenues, values of and responsibility for public funds and property are nearly as essential to the health officer as a knowledge of laboratory procedure and computing vital statistics. Business acumen will earn the health officer the respect and support of his superiors, colleagues, and subordinates.

The health officer is, then, of necessity, a business-man. Has he benefitted from association with teachers of business administration?

Personal — Finally, a few health officers seem to lack genuine, impelling faith in the cause. That their number is small is a tribute to public health teachers and to those responsible for selecting trainees. These few have somehow escaped the conviction that the game is worth the candle. One wonders if they will have the fortitude to withstand the woes which are inherent in any public service and are indigenous to public health. No group in this country has shown greater courage or greater devotion to a public cause than the old-time health officers who have held office for many years. They have borne, with little complaint: insecurity, inadequate income, niggardly appropriations, political and personal vituperative attack, changes of superiors with each political upheaval, the demands of an exacting and none too considerate public, the irritation of public and official stupidity, the dangers of deadly epidemics. One hopes that among our recruits of today we are numbering and developing more Chapins, Bundesens, Chesleys, Emersons, Bishops, Browns, Parrans, Mc-

Cormacks, and Godfreys.⁶ It seems essential that somewhere in the course of his training every student should be inspired by that faith in the cause which comes from inspired teachers and associates who "teach out of stimulating experience."

SUMMARY

These observations on the political, educational, administrative, and personal problems of our younger health officers lead to the following suggestions by way of summary:

1. We must all agree with Dr. Gregg's plea for better selection of candidates for health officer training. Under present arrangements for federal aid, this is not entirely the responsibility of the school. Candidates receiving federal aid are selected by the state health officers. Some state health officers have had difficulty in obtaining suitable staff members and have found it necessary for many years to do the best they could with any who were interested. With the advent of federal training for public health personnel and the increase of economic problems in the private practice of medicine, together with the tendency of modern youth to think more collectively, many young men of fine character and ability are now available. There seems no need longer to select any but the best.

2. The health officers' training must, of course, be technically complete and intensive. However, few health officers fail because of lack of professional knowledge. In fact, the well entrenched health officer can get along with surprisingly little technical knowledge. Few health officers can get along without considerable knowledge of statesmanship, political science, psychology, personnel management, and business administration. This knowledge will be better organized and more useful if more provision is made for gaining it

in the curriculum rather than leaving it to hit-or-miss observation. For instance, a frank study of politics "as is," together with consideration of the theories of government, will help fortify the health officer against disillusionment and to maintain his balance. These need not be long courses, but should be specially prepared for health officer needs.

3. It is surprising how little we really know about the job of being a health officer. Would it not be worth while to make a careful job analysis of several health officers' work such as is done with important positions in many industries? Having determined precisely what the average health officer does, how much time he spends on each of his known professional functions, how much time and in what manner he spends that time on his administrative duties, what his major problems are during the course of a year, we may then be in a better position to teach what he needs to know. If we might add to this a careful study of health officer success and failure, analyzing the causes underlying each, we might then keep our curriculum an active, vital factor in helping graduates to meet life situations.

4. Is it altogether necessary to surround the granting of a degree with pomp and circumstance? May it not be that graduate students, like elementary pupils, will show varying speeds of learning? May not some be ready for the degree in 9 months, while others may need 18? The completion of certain units with a certain grade on examination may shed little light on actual achievement and ability. Some may need more experience and less classwork, others more of both. Could not the degree be granted without ceremony at any time when the faculty and the state health officer are satisfied with the student's achievement?

5. An understanding of modern health education methods is one of the

most urgent needs of all health officers. Since the transition of public health from the legislative to the educational era, education has become one of the most important functions of the health department. It will remain an important function long after most of the contagious diseases and sanitary problems are conquered.

The science and art of education have advanced so rapidly that public health schools have failed to keep pace with modern methods. Today's health officer should be better equipped than anyone else in his community to help organize adult health education. He should be prepared to confer with teachers in their own language and to provide means of coöperating with the school health education program. If we bear in mind that the purpose of health education is to improve health behavior, and if we measure results to date in terms of that improvement, we shall be shocked with the extent of our failure. Considerable time should be devoted, therefore, to teaching our trainees modern educational methods.

6. One way for the trainee to learn and benefit from modern educational methods is to be subjected to them himself. For this, the graduate course in public health offers unique opportunities. We deal with men and women who have undergone rigorous and prolonged schooling. They are the survivors of a careful system of selection and elimination. They are, therefore, comparatively well educated. They have trained minds. They are intelligent. They have an unusual degree of motivation. We may assume that they are a select product of our educational system. We need not be concerned with the century-old educational conflict between cultural and professional elements. These students come to us for graduate professional training, for specialization.

This is the place for us to recognize

that "a coherent structure of thought and an integrated pattern of behavior are necessary to give meaning to specific facts and skills."⁷ This is the place for us to build a curriculum which will meet the ultimate test of true knowledge. Is this knowledge useful in life situations? We must provide actual experience outside the classroom in order to stimulate students to use books and laboratories intelligently. Such experience must be suited to each individual's needs and based upon the relative fertility or sterility of his previous training. We must measure progress by actual achievement rather than by grades and units. We must recognize that the only curriculum which is educative in the long-run is that which provides for a large measure of self-education. We must ask ourselves: "Do our graduates come out with a vision of what society might be, tempered by an understanding of things as they are, and implemented by a commitment to some specific undertaking wherein each can effectively take hold?"⁸ Only when this question can be answered in the affirmative will our academic degree carry some of the guarantee of measured competence to which Dr. Gregg referred. Whether that degree, then, is a C.P.H. or an X.Y.Z. will matter little to the school, the recipient, or the public.

Development of Tuberculosis in Infected Children*

ALTON S. POPE, M.D., F.A.P.H.A., PHILIP E. SARTWELL, M.D.,
AND DAVID ZACKS, M.D.

State Department of Public Health, Boston, Mass.

IN laboratory animals where time of infection and dose of bacilli can be controlled there is substantial agreement that primary infection with tuberculosis, if not overwhelming, results in a measurably increased resistance to subsequent inoculations with tubercle bacilli.^{1, 2, 3} In man the picture is less clear. Although the typical parenchymal infiltration of primary infection, followed by resolution, fibrosis and calcification, is not infrequently observed roentgenologically, the exact date of reinfection and the duration of exposure are rarely known, and the dosage of bacilli is wholly problematical. Furthermore, it has not been demonstrated how far the results of inoculation experiments with tuberculosis in laboratory animals can be applied to natural infection in man.

From a public health standpoint the relationship between primary infection with tuberculosis and the development of subsequent progressive disease has become a problem of major importance. Is a primary infection acquired during childhood a relative safeguard against subsequent exposure? or does the sensitization acquired through such infection result in increased susceptibility to destructive lesions?

Much evidence might be cited to

support both opinions, and the epidemiological findings so far reported appear to be contradictory.⁴⁻⁹ Obviously the answer is not simple and the diversity of opinions based on extensive studies at least suggests that the end results may be strongly conditioned by such variables as the type of population exposed, the level of tuberculous infection in the community, and various environmental factors. Such complications make it difficult to compare directly the findings of different investigators, but for practical purposes the amount of tuberculous disease which in sufficient periods of time develops in properly controlled population groups appears to be the best measure of the significance of childhood infection in the evolution of phthisis.

In connection with its field clinic work on tuberculosis in school children, the Massachusetts Department of Public Health has during the past 15 years attempted to collect evidence on the relationship of childhood infection to the subsequent development of progressive tuberculosis in adolescents and young adults. On account of the long, indeterminate incubation period of tuberculosis and the slow development of clinical disease, it has been necessary to employ epidemiological methods which would give a perpendicular rather than the usual horizontal picture of the situation. The main object has been to obtain a quantitative measurement of

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 20, 1939.

the amount of progressive tuberculous disease subsequently developing in large groups of children examined in the clinics, classified according to age and sex, the initial reaction to the tuberculin test, roentgenological evidence of tuberculous disease, and known household contact with tuberculosis.

The basic material to be presented consists of the data on some 400,000 school children tuberculin tested in the Chadwick Clinics between 1924 and 1934, the reëxamination of certain groups of these children, and the cases of pulmonary tuberculosis subsequently reported in the entire group. During the first 3 years of the clinic children were selected for examination on the basis of known exposure to tuberculosis, under-

weight of 10 per cent or more, definite or suspicious symptoms or signs of pulmonary disease. For the next 2 years all school children for whom consents were received were examined, irrespective of special indications. During these 5 years complete physical examinations were made on all children examined, in addition to the von Pirquet test and roentgenogram of the chest of all positive reactors. During the last 5 years examination was limited to the tuberculin test of all children, with X-ray of reactors and physical examination only for children with positive roentgenograms. All children with roentgenological signs of either childhood or adult type tuberculosis were reëxamined annually with X-ray of the chest, and

whenever possible followed to the end of their school life.

The problem has been approached from several angles and the data are presented in the form of two series of observations:

1. Reported subsequent morbidity and mortality from tuberculosis in the entire group of children tested

2. The development of tuberculosis in children under annual observation of the clinic

FIRST SERIES

Soon after the beginning of the Ten Year Program an alphabetical-geographical card index was set up for all children examined in the clinics, making it possible to check any subsequent developments against a child's status at the time of first examination. By means of this index all cases and deaths from pulmonary tuberculosis reported in Massachusetts from 1924 to 1936, inclusive, in the age groups covered by the Ten Year Program were checked to determine whether the individuals in question had ever been examined in our clinics. The diagnosis of tuberculosis in each report or death certificate was confirmed before it was included in the study. Thus a list was established of verified cases and deaths from tuberculosis which had developed in a period of 13 years in a group of some 400,000 children. The morbidity and mortality in this group up to 1934 have been reported previously by one of us.¹⁰ It is probable that the reporting of cases is somewhat more complete in the group of reactors followed in the clinic than in the general population, but there is certainly no such weighting of the deaths reported. The cases and deaths from tuberculosis, together with morbidity and mortality rates, according to the tuberculin reaction on first examination are shown in Tables 1, 2 and 3.

In spite of the significantly higher morbidity and mortality among the children who reacted to the initial

tuberculin test, the case fatality rate has been slightly higher among cases in children originally tuberculin negative. This would appear to cast some doubt on the benign character of first infections acquired between the ages 6 and 16. It will be noticed that the median interval between the tuberculin test and death in fatal cases is essentially the same among the originally negative and originally positive reactors.

SECOND SERIES

Of the children tested, X-rayed, and examined in the school clinics, a large number were, for reasons given above, kept under annual observation with X-rays and physical examinations. For statistical analysis all those were selected who did not have pulmonary tuberculosis or non-tuberculous pulmonary disease on first examination and who were reexamined by X-ray at least once, a year or more subsequently. A total of 19,346 satisfied these requirements. Their mean age at the beginning of the period of observation was 11.4 years, and the mean period of observation was 3.4 years, with a maximum of 11 to 12 and a minimum of 1 to 2 years.

While these observations are based on a large experience, they have certain limitations which should be pointed out. The von Pirquet test was used throughout the study; however, specially trained physicians made both the tests and the interpretations, and multiple tests were often performed. Cases were classified as "contact" when a history of exposure to tuberculosis at any time since birth was obtained from either the parents or health department, and it was usually not possible to verify this by examination of the supposed contact or to find previously unsuspected sources of infection. In the majority of cases listed as contacts, contact had been broken when the child came under observation. A positive contact history was obtained in 33.9 per cent of the

With positive X-ray ²	90	7.7	38	3.0	128	5.1

1. This applies to all cases developing pulmonary or extrapulmonary tuberculosis during study, and includes those who have subsequently died.

2. "Positive X-ray" here refers to those who when first tested and examined showed old childhood-type lesions in parenchyma, hilum, or both locations. These were generally calcified, and might be single or multiple.

cases of childhood type tuberculosis, in 27.4 per cent of the reactors with negative X-ray, and in 67.7 per cent of the non-reactors in this series; the high figure for non-reactors means of course that the usual reason for keeping them under observation was a contact history.

Two methods of analysis were applied to determine the frequency of breakdown from tuberculosis. The first, or cumulative morbidity method, was suggested by Frost and used by Brailey¹¹; a description of the mathematics involved is given by Puffer, Stewart, and Gass.¹² Table 4 illustrates its application to the entire series; Table 5 shows the cumulative morbidity as derived in the last column of Table 4, by years for each group. While some children were followed for 11-12 years, the figures for

the last few years are unduly influenced by a single breakdown, since the number remaining under observation is small; therefore in Table 6, which divides the groups according to contact, the morbidity is taken only at the end of 7-8 years of observation. Since no differences were noted in the distribution of cases of pulmonary tuberculosis and of other reinfection forms of the disease, all are included together in the tables. There was a total of 142 pulmonary cases, 8 pleural effusions, and 13 extra-pulmonary cases; 31 deaths from tuberculosis occurred during the study.

As this method takes into account years of observation but not age, it was felt that another approach based on age might further illuminate the problem. The method adopted is one used by Herlitz⁶ and is illustrated in Table 7.

Difference			169.3±21.1

The number of children under observation at each age is obtained by counting each child as many times as he is years under observation; e.g., if a child was followed from 8 to 10, he is included in the totals for ages 8, 9, and 10. The observations were carried only to age 19 although a few persons had been followed into adult life. The expected number of breakdowns at each age in a group of known size can be computed from the age specific morbidity rates of the group with which it is being compared, and its difference from the actual

observed number of breakdowns noted. Table 8 presents a comparison of the major groupings by this method, and Table 9 gives the morbidity rate by ages.

It will be seen by reference to Tables 4 to 9 that the incidence of tuberculosis remains at a low level up to about the age of 10, after which it rises steadily, and much more rapidly in girls than in boys. It is this lag between infection and the development of active disease which makes the relationship so difficult to appraise. Many children are

TABLE 9
Morbidity by Age

18	2,822	10	0.4
19	1,371	13	0.9

lost from observation before they reach an age at which they are likely to develop tuberculosis, and among those who are followed it is often impossible to determine with any certainty the time and degree of any subsequent exposure. All of our evidence indicates that in school children it is the age of the individual rather than the time of exposure or any environmental factor which determines the time at which tuberculosis develops. It will also be noted that the incidence of tuberculosis is higher among original reactors to the tuberculin test than among non-reactors, and significantly higher among those whose original X-rays showed evidence of childhood type tuberculosis than among reactors with negative films; and that it is higher in each group among contacts than non-contacts.

SUMMARY AND CONCLUSIONS

In a group of some 400,000 Massachusetts school children tuberculin tested in the period 1924-1934 the subsequent reported morbidity and mortality from tuberculosis has been determined to the end of 1936, and rates have been computed on the basis of the original reaction.

Among the reactors the morbidity from adult type tuberculosis has been approximately 4 times that in the non-reactors. The death rate has been 3 times as great in the reactors, and the

case fatality essentially the same in the two groups.

The cumulative morbidity from tuberculosis in children reexamined annually for 10-11 years was over 6 per cent. This rate was approximately twice as high in females as in males, was substantially higher among reactors than among non-reactors and among reactors was over 3 times as high in those with originally positive roentgenograms.

For this second series the tuberculosis morbidity among children with a history of family exposure to the disease was $2\frac{1}{2}$ times that in children without known exposure.

Age specific morbidity rates in the series show that significant tuberculosis in school children is infrequent below the age of 10, that the incidence rises rapidly after this age, and much more rapidly in girls than in boys.

Food Poisoning Due to Staphylococci

With Special Reference to Staphylococcus Agglutination by Normal Horse Serum*

GLENN G. SLOCUM, PH.D., AND B. A. LINDEN

Associate Bacteriologist; and Assistant Bacteriologist; Food and Drug Administration, U. S. Department of Agriculture, Washington, D. C.

SINCE 1930, when Cary, Dack, Woolpert, and Wiggers¹ demonstrated that staphylococci are capable of causing food poisoning, many outbreaks have been recorded in the literature in which these organisms have been incriminated. There is little doubt that staphylococci are the most frequent causes of food poisoning in the United States at the present time. A survey of the literature on staphylococcus food poisoning indicates that bakery products, particularly those containing a cream or custard filling, have most frequently been involved in this type of food poisoning, although various other food products, such as milk,^{2, 3, 4} gravy,⁵ cheese,⁶ and meat,⁷ have been occasionally incriminated.

It is the purpose of this paper to point out another type of food product which, in the experience of the authors and their associates, is involved so frequently in staphylococcus food poisoning as to warrant particular attention. Dur-

ing the past 4 years and particularly during the past 2 years the Division of Bacteriology of the Food and Drug Administration, U. S. Department of Agriculture, has been called upon to conduct laboratory examinations of specimens of the so-called "ready to eat" hams which were collected in connection with food poisoning outbreaks. In every instance in which the epidemiological evidence definitely implicated ham as the food involved in the outbreak, laboratory investigation has revealed the presence of large numbers of staphylococci, which were demonstrated to be food-poisoning types, either by feeding sterile culture filtrates to young cats or by the intraperitoneal injection of boiled filtrates into kittens or young cats as described by Dolman, Wilson, and Cockcroft,⁸ and Dolman and Wilson.⁹

Up to the present time 10 such outbreaks have been studied, 8 of which have occurred during the past 2 years, and 5 of these during the past summer. In addition to the above outbreaks in which laboratory investigations were conducted, we have in our files reports on 8 additional outbreaks in which, although samples were not available for examination, the epidemiological evidence, symptomatology, incubation pe-

* Read at a Joint Session of the Food and Nutrition and Laboratory Sections of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 18, 1939.

The data pertaining to the studies on food poisoning staphylococci are taken from a thesis presented by Glenn G. Slocum, in June, 1939, to the faculty of the Graduate School of the University of Maryland, in partial fulfillment of the requirements for the degree of Doctor of Philosophy.

riod, and other information leave little doubt that they were caused by staphylococci.

Two further outbreaks were investigated which are of interest in that they followed the consumption of beef tongue, a salt-cured meat product. One of these outbreaks was investigated and reported by Dack, Bowman, and Harger.⁷

In all, these 20 outbreaks in which ham and beef tongue were implicated, affected at least 1,028 individuals. Two deaths occurred among these victims, neither of which was attributed directly to food poisoning, but rather to other complicating conditions.

In many of the outbreaks studied in this series there is little evidence to indicate the source of the staphylococci or when, in the process of manufacture, distribution, and handling prior to consumption, the organisms gained entrance into the products. In many instances there appears little doubt that the formation of enterotoxin, and perhaps even the contamination of the meat, resulted from improper handling in the hands of the consumer. In other outbreaks the evidence suggests that contamination occurred prior to the time the meat reached the ultimate consumer. The problem does not appear to be peculiar to any particular manufacturing plants, but rather to the type of products involved.

Although the literature does not contain many references dealing with staphylococcus food poisoning in which ham or related salt-cured meat products have been involved, we have reason to believe that such products are quite commonly the cause of food poisoning but have failed to receive publicity or attention. Stone¹⁰ has reported 7 outbreaks caused by consumption of "baked" ham or related salt-cured meat products in which he has demonstrated enterotoxic staphylococci as the probable cause. Personal conversations or communications with various public

health workers have revealed that it is not uncommon to encounter such outbreaks frequently during the summer months.

Kelly and Dack¹¹ conducted a study to discover whether staphylococci would grow and produce enterotoxin in meat sandwiches as a result of the outbreak reported by Dack, Bowman, and Harger⁷ in which pickled beef tongue sandwiches were involved. They noted that staphylococci were the predominating contaminants in salt-cured ham and tongue and demonstrated that staphylococci would grow in such products in which the salt concentration was sufficient to prevent the growth of bacilli. They further demonstrated that staphylococci would develop in sandwiches and produce enterotoxin therein. Therefore, it appears that ham is a favorable medium for growth and production of toxin by these organisms.

In the course of laboratory investigations of the above mentioned outbreaks, as well as others in which a variety of food products were implicated, we have been constantly impressed, as have other workers in this field, with the need for more simple and rapid laboratory procedures for the identification of food-poisoning staphylococci.

Recognition of this need led to the study by the senior author of a series of 37 cultures isolated from specimens of ham and other food products involved in 11 outbreaks of food poisoning. All but 2 of the 37 cultures were considered enterotoxic strains at the time of isolation, as indicated by toxicity tests, but in 2 instances evidence of toxicity was based only on the bacteriological and epidemiological investigations. A study of the ability of these strains to produce enterotoxin revealed that during storage on laboratory media the great majority of the strains had lost this characteristic. It also appeared that storage had diminished the ability of the majority of the strains to liquefy gelatin actively,

that is, to produce a positive Stone reaction on Bacto Stone's extract gelatin agar. Only 3 strains produced definite positive Stone reactions, and of these, only 2 produced enterotoxin, as determined by the technic described by Dolman and Wilson.⁹ Three strains isolated from a specimen of ham during the course of this investigation, while capable of producing enterotoxin, did not produce a positive Stone reaction. On the basis of these two properties the strains in this collection could be divided into 4 types. Thirty-one strains were enterotoxin negative, Stone negative; 1 strain enterotoxin negative, Stone positive; 2 strains enterotoxin positive, Stone positive; and the 3 recently isolated strains were enterotoxin positive, Stone negative. This would seem to confirm the observations of other investigators that gelatin liquefaction on the Stone medium is not a reliable index of the ability of the strains to produce enterotoxin.

Other attempts were made to differentiate the enterotoxic from the non-enterotoxic strains with results which appeared to be of some significance. The enterotoxic strains were found to produce as much, and in the case of the Stone positive strains, more, hemolysin for rabbit erythrocytes than did any of the non-enterotoxic strains. All of the enterotoxic strains produced a small amount of hemolysin for human erythrocytes, while none of the non-enterotoxic strains produced any appreciable amount of this hemolysin.

A study of the behavior of these strains of staphylococci in the presence of normal horse serum was prompted by the observations of Beumer,¹² who showed that while the addition of normal horse serum to broth prevented the production of hemolysin by most pathogenic staphylococci, certain strains were capable of producing hemolysin in its presence. He presented evidence that the ability of these strains to pro-

duce hemolysin in the presence of horse serum was caused by the destruction of the normal antilysins by the proteolytic breakdown of the serum proteins by these strains. Since the evidence presented by Stone¹³ and other investigators indicates that enterotoxic staphylococci are more active in their ability to liquefy gelatin than non-enterotoxic types, it appeared possible that they might also be more actively proteolytic on horse serum. However, when the strains in this collection were grown on coagulated horse serum, and on coagulated horse serum containing 3 per cent Difco beef extract, their proteolytic activity exactly paralleled their activity on Bacto Stone's extract gelatin agar. When grown in broth containing 20 per cent horse serum the enterotoxic Stone positive strains were found to be capable of producing hemolysin for rabbit erythrocytes. None of the non-enterotoxic strains, including the one strain which gave a positive Stone reaction and was proteolytic on coagulated horse serum, was capable of producing this hemolysin in broth containing horse serum. However, the recently isolated enterotoxic Stone negative strains would produce hemolysin only when grown in a partial atmosphere of carbon dioxide, but when grown under such conditions, produced much greater quantities of hemolysin for rabbit erythrocytes in the presence of horse serum than in its absence. Since other strains in the collection produced hemolysin in the presence of horse serum when grown in a partial atmosphere of carbon dioxide, the value of this method appeared limited for all practical purposes.

Finally, these strains were studied in their relation to the normal agglutinins in horse serum. These studies revealed a marked difference between the enterotoxic and non-enterotoxic strains in this collection in their agglutinability by normal horse serum. When living suspensions of the staphylococci were

mixed with varying dilutions of normal horse serum and incubated at 37°C. for 24 hours, selected non-enterotoxigenic strains were completely agglutinated in serum dilutions of 1:160 or 1:320, with the formation of large aggregates or clumps. Under the same conditions the enterotoxigenic strains were only partially agglutinated in serum dilutions of 1:80 and 1:160, and this agglutination was of the finely granular type. In the lower serum dilutions the enterotoxigenic strains showed marked growth with production of a heavy, diffuse turbidity. This suggested that the serum agglutinins had been destroyed during growth of the enterotoxigenic strains but since one of these strains had previously been demonstrated to be devoid of proteolytic activity on coagulated horse serum, and since the non-enterotoxigenic strains were completely agglutinated in comparatively high serum dilutions, it would appear that the difference in agglutinability was caused by some other inherent characteristics of the strains. In order to minimize the factor of growth, other tests were conducted in which incubation was carried out at 37°C. for 3 hours, followed by storage at 7°C. over night. Under these conditions, the enterotoxigenic strains failed to agglutinate while the non-enterotoxigenic strains were completely agglutinated in 1:10 serum dilutions, and almost completely in a dilution of 1:20.

With a full realization of the limitations imposed upon any interpretation of the above results, since only one horse serum and a few staphylococcus strains were studied, the results strongly suggest the probability that a fundamental difference exists between enterotoxigenic and non-enterotoxigenic strains of staphylococci in their agglutinability by normal horse serum. Further investigations have been started with other horse sera and known enterotoxigenic and non-enterotoxigenic strains of staphylococci, in order to determine whether this agglu-

tion phenomenon is sufficiently characteristic to be of differential value.

SUMMARY

1. The occurrence of 20 outbreaks of food poisoning apparently due to staphylococci, all of which followed the consumption of "ready to eat" hams or tongue, is discussed. The public health problem presented by the incidence of staphylococcus food poisoning, involving "ready to eat" ham and related salt-cured meat products, appears to be as great as that presented by custard-filled bakery products.

2. A study of 37 strains of staphylococci isolated from food involved in 11 outbreaks of food poisoning demonstrated that the great majority of the strains had lost their ability to produce enterotoxin and to produce a positive Stone reaction during storage on laboratory media.

3. A fundamental difference between the enterotoxigenic and non-enterotoxigenic strains studied, seems to be indicated by the fact that they differ markedly in agglutinability by normal horse serum.

ACKNOWLEDGMENTS — Acknowledgment is made to the Food and Drug Administration of the U. S. Department of Agriculture for permission to present the data given in this paper and to Dr. A. C. Hunter, under whose direction this work was carried out.

Cost of the World War*

IN money the World War cost \$337,-846,000,000, of which \$189,000,000,-000 was spent directly, the remainder consumed in destruction of property and stoppage of industry.

It cost the United States \$32,000,-000,000, plus continuing costs of \$19,000,000,000, making a total of \$51,000,000,000.

\$51,000,000,000 would pay the cost of running the public elementary, high schools and colleges and universities for 17 years; would build two million miles of paved roads, which is three times the total mileage of surfaced roads now in use; would construct 15 million six-room houses; put 16 hospitals costing one million dollars each in every one of the 3,073 counties of the United States; and pay the unemployment-insurance premiums of everybody in the United States for more than 100 years at the New York State rate.

\$51,000,000,000 would do all of the following: wire all the 9,400,000 homes in the United States which do not have electricity; pay all the farm mortgages; install bathrooms with running water in the 80% of farm homes which do not have them now; double the present endowments of all institutions of higher

learning in the United States; build four consolidated high schools at a quarter of a million dollars each in every county of the United States; put a million-dollar airport in every county; build 10 bridges like the Tri-Borough Bridge; build another canal across the Isthmus; establish a five-billion-dollar program for the prevention of floods and soil erosion; set up an endowment fund which would provide \$100 a month for every blind person and deaf mute in the United States; finance the entire recovery and relief program from 1932; and endow an organization which would carry on the work of the League of Nations, the World Court and the International Labor Organization.

Combined national debts of all countries were increased from \$43,000,000,-000 to \$400,000,000,000. The cost of living was doubled. More than \$4,000,-000,000 of the expenditures annually in this country are the direct or indirect results of the World War.—Arthur W. Hawkins, Vice-President, Lincoln Bank and Trust Company, Syracuse, N. Y. *Westinghouse Magazine*, 11, 10 (Oct.), 1939.

Premarital and Prenatal Tests for Syphilis in New Jersey*

JOHN HALL, F.A.P.H.A.

Division of Venereal Disease Control, State Department of Health, Trenton, N. J.

THERE are interesting human sides of the story about blood tests for syphilis before marriage and during pregnancy, but I must stick close to this rather prosaic outline of our experiences in New Jersey:

- Why these laws happened to be passed.
- What they are.
- How they work.
- What the figures show.
- What we are doing with their results.
- How they are considered by our people.

Agitation in favor of a *Premarital Medical Examination* law, aimed particularly at the prevention of syphilis, was started in New Jersey in 1936 by what is known as the New Jersey Health and Sanitary Association. The idea was taken up and carried on aggressively by numerous other organizations, including the press, and was eventually sponsored in the Legislature by the State Department of Health. A letter of approval from Dr. Parran, reproduced and circulated widely, was a very effective part of our ammunition. Various forces had just begun to work stirring up a far greater interest than ever before in the venereal diseases and promoting a desire to do something about them. The general principle of this "*Marriage Bill*" could be readily understood, and it was one objective toward which any-

body could take definite steps easily and soon. Our legislators were impressed with the popular demand for action and, although there was an undercurrent of disapproval from some church groups, it was not difficult to secure the passage of the bill in the spring of 1938.

The "*Prenatal Bill*" was introduced in the same session of the Legislature, got the benefit of the publicity being given to a similar new idea in New York State, took on some of the momentum then moving more or less everything with a venereal disease flavor, and was passed without the slightest opposition.

The program of education, which has been one of the activities of the State Health Department's Bureau of Venereal Disease Control for twenty years, was a good background and, no doubt, played a real part in the general approval of these two new laws.

WHAT THE PREMARITAL LAW IS

We followed the lead of Connecticut with our *Premarital Bill* and got much valuable assistance and advice from their State Health Department, which had had practical experience during two years. Our law as passed was substantially as the bill had been drawn and, boiled down, is this:

It deals with syphilis only. Not more than 30 days before getting a marriage license, each person must secure a certifi-

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 17, 1939.

cate form divided in two parts. On one part an approved laboratory states that a blood sample from the person has been tested, but the *result* of the test is not given. On the other part of the form a "qualified physician" from any state, says that, after examining the person and considering the result of the blood test, it is his opinion "*that the person is not infected with syphilis or, if so infected, is not in a stage of that disease which may become communicable.*"

HOW THE PREMARITAL LAW WORKS

Several features of this law are probably responsible for the relatively little difficulty it has caused. It attempts to do only one rather definite and fairly simple thing, and it puts the responsibility for the decision on the physician. A provision of our law, which we have not seen elsewhere, is a real help in its administration. These certificates, mentioned above, must go along with the marriage records until they reach the Bureau of Vital Statistics of the State Department of Health to be permanently filed. This makes it possible for us to know how well the law is being observed and to check up on any source of irregularity. This is not very easy to do, if the health certificates are allowed to stay in the hands of the local officials who issue the licenses, as appears to be the practice in other states. In this connection let me say that, after the first few months, these certificates have come back with remarkable completeness so that not more than one or two are now irregular or missing from the several thousand marriage records filed each month.

DECREASE IN MARRIAGES

The influence of our law on the *number of marriages* has apparently been the same as in Connecticut and elsewhere. There was a sharp reduction after July 1, 1938, when our law went

into effect. Comparing marriages since that date with the previous year *alone* is not fair, because, in 1937, there were 3,400 *more* marriages in New Jersey than in any other year on record. Using for comparison the averages of corresponding periods of 1935-6-7, there was a 20 per cent reduction in marriages during the first 6 months of the law, but only a 7 per cent reduction in the second 6 months.

Pennsylvania has a law very similar to ours which will go into effect in May, 1940, and which will stop what little leakage of New Jersey marriages there may still be over our western border. New York's law started at the same time as ours did and effectively prevented people who wanted to avoid such requirements from going there.

APPROVED LABORATORIES

We have 85 laboratories, public and private, all in New Jersey, that are approved by the State Department of Health for making the premarital and prenatal blood tests. Incidentally, we have a system of checking our laboratories' tests by the use of standardized dried blood sera, but that is not a part of this discussion. An arrangement is in effect with the New York City Health Department whereby we accept their tests and they accept those made by our department. We expect similar reciprocity plans will eventually be made with the New York and Pennsylvania State Health Departments.

PREMARITAL BLOOD TESTS

Nearly all of the approved laboratories in New Jersey have made quarterly reports on the numbers of their premarital blood tests. We learn in this way that 62,764 such tests were made in the first full year of our law (July, 1938, through June, 1939). During this time, 56,664 persons were married in the state. Of these tests, 847 were positive. This is 1.35 per cent.

When you consider that repeat tests are often made on the positives, but almost never on the negatives, the actual number of persons with this evidence of syphilis is less than 847, as stated above. We have checked the names of those with 583 positive tests back and forth among four laboratories and found that only 62 (10.6 per cent) were duplicates. We feel that this small percentage of repeats is an indication that physicians do not have positive tests checked as regularly as they should, and we have broadcast a message to that effect. A printed set of suggestions about interpreting premarital blood tests,* which was sent by mail to all registered physicians in the state before the law went into effect, reads as follows on this point: "A *strongly positive* serologic test presumes the presence of syphilis, but it is wiser to repeat test before informing the applicant, unless a definite history of infection is obtained. . . . *Doubtful* reactions call for further physical examination and a repetition of test." Incidentally, this matter of duplicate positives is worth remembering in collecting statistics on the prevalence of syphilis in any groups that may be tested.

That positive tests should amount to only 1 per cent may seem a very small mouse to come out of all this mountain of legislation, expense, and fuss. But when you consider that it means at least 760 different persons in New Jersey, that a large proportion of them evidently had no previous knowledge of their infection, and that—as you will hear in a minute—many people in the earlier stages of syphilis are thus being persuaded to postpone marriage and start regular treatment, you will probably agree with us that our law is producing something of real value.

The U. S. Public Health Service has

published an article¹ in *Venereal Disease Information* which aims to prove that 1 per cent of apparently healthy young people planning to get married, or any other similar group, is entirely consistent with Dr. Parran's original statement—often misquoted and frequently misunderstood—"syphilis strikes one out of every ten adults."²

WHAT THE FIGURES SHOW

Several facts regarding our premarital blood tests will have to be stated very briefly.

The 62,764 tests were made as follows:

	Per cent
At the State Health Department Laboratory	48
Also without charge at 15 other public laboratories	47
At 69 private and hospital laboratories	5

From 521 persons with positive tests made at 4 laboratories the following facts were derived: 52 per cent were men, 48 per cent women, 53 per cent white, and 47 per cent Negroes.

WHITES AND NEGROES

We have gone into this matter of whites and colored in a great deal of detail with 48,000 tests at four laboratories. It appears that about 0.6 per cent of the white persons tested are positive as compared with 11.0 per cent of the Negroes. This is a relationship of about 1 to 18. If this is true of our people as a whole (I have no proof that it is), it would indicate that the Negro 5 per cent of our population has half the syphilis. It is obvious from these and many other figures that, in quoting the numbers or percentages or almost anything about syphilis, we must be careful to consider this racial difference, and perhaps to give it much more attention than we are doing in our syphilis control programs.

* Samples of forms may be obtained from the State Department of Health, Trenton, N. J.

WHAT IS BEING DONE ABOUT IT

In New Jersey we have no system whereby the names of positive reactors to tests for syphilis are reported from all other laboratories to the State Department of Health. However, the success of an experiment in checking up on persons who have positive premarital tests in our department has made available to us the records of three other large laboratories. Now 85 per cent of the tests in the state for premarital purposes are a part of a routine which brings us a great deal of information.

A carefully worded questionnaire about each person whose premarital blood test is positive is mailed to the physician who sent in the sample after about 3 months. We ask for confidential data in 7 questions which cover the following points:

Did you give the certificate authorizing the issuance of a marriage license?

If not, did or did not the person get married?

Is, or is not, the person getting treatment?

Provision is made in the last two pairs of questions for the answer, "I don't know."

All the doctor needs to do is to check a square to answer a question. A space is also provided where a check mark serves to report a potentially infectious person as delinquent from treatment and, therefore, no longer protected against investigation by the ethics of confidence.

For the sake of simplicity, I report here only on the 282 persons with positive tests made in the State Laboratory during the full year. Results from nearly as many other persons tested at the three other laboratories are proving to be substantially the same.

It is interesting to note that 95 per cent of these 282 questionnaires were filled out and returned by the physicians. They contain a great deal of information both individually and collectively. Many physicians go to considerable effort in explaining their answers to the ques-

REPORTS FROM PHYSICIANS ON 282 POSITIVE PREMARITAL CASES

(From New Jersey State Health Department Laboratory—1 year)

	<i>No.</i>	<i>Per cent</i>
Marriage certificates granted	120	43
Marriage certificates refused	147	52
No report	15	5
Total	282	100
Of those 147 refused certificates:		
Did not get married	90	61
Married out of state	29	20
Result not known	28	19

Three months after the tests:		
Under treatment	153	57
Not under treatment	35	13
Disappeared	69	26
Not stated	10	4
Total	267	100

Reported by physicians as delinquent, to be followed up

At least half of the delinquents are being located by local boards of health and persuaded to continue treatment.

tions, and there has not been a single complaint of impropriety in our asking for these facts.

I can give you here only the briefest kind of a summary of the results of these efforts to find out what our marriage law really does.

HOW THE LAW IS CONSIDERED

Many physicians accept our invitation to comment on the premarital law in a space on the questionnaires. We have pages full of these quotations, only two of which I shall give. These are typical, and are repeated in different words again and again.

"The law in general is an excellent public health measure and seems to be well taken by the public."

"Prompt in treatments and coöperative. The law has great value; this patient was found only because of the law."

Six months after the law went into effect we sent a circular letter to a number of local registrars of vital statistics—the persons who issue marriage licenses—asking for an account of their experiences and requesting suggestions for simplifying the procedure or making the requirements of the law better known. There was a remarkable uniformity of approval in the 26 replies which were received.

We feel that there has been real value in the widespread publicity given to the law, both before and after it was passed, in which we had the whole-hearted support of the press, and which included the distribution of many thousands of copies of a simple leaflet of questions and answers issued by the State Department of Health. This is no doubt another reason for the general acceptance of the law and the smoothness with which it runs.

Here is one more quotation, somewhat exceptional it is true, but which we believe is an indication that our intensive program of education is making some impression on the people of our

state. A physician wrote on a premarital questionnaire: "I find that this woman has been married for 4 years. While drunk she walked into my office, said she was going to get married, and asked for a blood test."

THE NEW JERSEY PRENATAL LAW

The story of our *Prenatal Law* is much less complete and definite. For one thing, it has been in effect only since January 1 of this present year; for another, it is of such a nature that its provisions are harder to enforce and its results far more difficult to see.

Briefly, this law provides that physicians shall take blood specimens for tests for syphilis from all pregnant women at the time of the first examination. Midwives, and others not authorized to take such samples, shall call in a qualified physician for the purpose. Birth and stillbirth certificates must include a statement of whether or not the mother's blood was tested, *but not the result*. If the test was made, the approximate date shall be given.

It is obvious that this is largely an educational measure, as there are no penalties for its avoidance and no specification that treatment shall follow positive blood tests. As with the marriage law, a great deal of publicity was given to this by the press and through various other channels available to the state and local departments of health.

From what we can learn, this law is well thought of, and we have already been able to collect a lot of figures.

PRENATAL BLOOD TESTS

Laboratories often do not know which blood specimens are from prenatal cases because there is no requirement that they be so identified. In many instances, however, the forms that accompany the blood samples are marked, and from 58 laboratories we learn that during the first 6 months of the law 19,752 prenatal tests have been made. Of these,

272 were positive. This is 1.38 per cent, almost the same as the percentage of positive premarital tests. So far we have been able to break down only a few of the figures, but from our state laboratory it appears that about 0.4 per cent of the white women tested are positive and about 6.0 per cent of the Negroes.

We have been agreeably surprised at the way in which the information about the tests has been given on birth certificates, in spite of the fact that it has taken a long time to get the new forms, with spaces provided for the purpose, out into circulation. During the month of March, 56 per cent of the birth certificates that came in had the notation about prenatal tests. In May there were 69 per cent; in August 84 per cent; in September 87 per cent.

The essence of the matter is, of course, to get the tests made *early* so treatment, if needed, can be most effective. We have secured some information from birth certificates for the month of May on this point, representing 3,232 women who were tested. This is condensed as follows:

<i>Tests Made</i>	<i>Per cent</i>
Prior to 5th month of pregnancy	20
In 5th month	17
In 6th month	14
In 7th month	13
In 8th month	8
In 9th month	20
Month not stated	8
	<hr/> 100

PRENATAL QUESTIONNAIRES

The *premarital* questionnaire scheme proved to be so successful that we are trying it on the *prenatal* cases with positive blood tests. These sheets make it easy for the physicians to answer the following questions: At what time in pregnancy was this test made? Was the presence of syphilis formerly known to the woman? Has treatment previously been given? Has treatment been given in this pregnancy? If the baby has been

born, what is its condition? Does it have any evidence of syphilis? What do you think of this law?

While these facts are not yet available about large numbers of cases, it is interesting to note what we have learned in 6 months.

One hundred and twenty-seven questionnaires went out; 114 have been returned—90 per cent; 12 were eliminated as not syphilis or not pregnant.

Tests were made at all times in pregnancy, almost equally distributed through the 8 months. Only 15 per cent of the women admitted knowing they had syphilis, and 14 per cent said they had *previous* treatment. Treatment was followed *since* the tests by 70 per cent.

Sixty-two pregnancies were definitely reported as terminated.

Forty-nine apparently healthy babies had been born.

Three obviously had syphilis.

Seven were stillbirths or miscarriages.

Three babies died soon after birth.

It appeared that very few blood tests on babies had been made.

You will readily realize that painstaking efforts on our part must be carried out over a much longer period to collect such facts in sufficient volume to be really valuable, and it is our intention to see that this is done. In fact, it is our obligation, after advocating the passage of both of these laws, to learn as much about their results as we can.

No matter if a law or a regulation, or anything else, appears to be perfect and its administration has been made as nearly foolproof as humanly possible, there are bound to be special cases and other reasons why its actual operation is not 100 per cent. I illustrate by one more quotation, again from a physician who wrote this on one of our premarital questionnaires: "This woman has twins by the person she was about to marry. Under the circumstances I thought best to grant the certificate but,

for reasons unknown to me, the marriage did not take place." Here we have a woman with twins, a blood test, syphilis, a health certificate, and a man—and still she didn't get married.

SUMMARY

Widespread public interest in the subjects of premarital and prenatal tests for syphilis, carefully prepared legislation, and a great deal of publicity are evidently the reasons the machinery of the new laws runs smoothly.

Large numbers of blood tests for syphilis are being made on young adults who would not otherwise have them. New cases are being found at the rate of about 1 per cent of those tested, which means at least 1,000 persons in the state in the course of a year. Many of these people, it appears, have no previous knowledge of their infection.

Most of the tests are made in public laboratories. Premarital positive tests are equally divided between men and women.

Negroes with syphilis outnumber whites by a wide margin on a percentage basis (at least 15 to 1).

Physicians are ready and willing to tell the State Department of Health, by means of simple questionnaires, what happens to the persons who have positive premarital and prenatal blood tests.

Premarital Tests

Nearly half (43 per cent) of the persons with positive tests are being given the certificates and are getting married.

More than half (57 per cent) of all those with positive tests are under treatment for at least 3 months.

Good coöperation is secured from physicians and health officials in following up delinquents from treatment.

Prenatal Tests

The law requires that statements be put on birth certificates as to whether or not blood tests were made on the mothers during pregnancy. This is being done at an increasing rate—87 per cent after the law had been in effect for 9 months.

The time in pregnancy when tests are made is stated on the birth certificates. Only 20 per cent of the tests appear to be prior to the 5th month.

Only 14 per cent of 102 positive cases had had previous treatment, but 70 per cent had treatments after the prenatal blood tests. Studies are being made of the condition of babies born, the presence or absence of syphilis, and the relation of time of prenatal tests and amount of treatment.

Physicians, registrars of vital statistics, and health officials questioned report almost unanimously that both these laws are well received by the public, have valuable educational features, and in their opinions are sound procedures in public health.

Public Health Degrees and Certificates Granted in 1938 and 1939

THE Committee on Professional Education of the American Public Health Association presents a report of public health degrees and certificates granted in the calendar years 1938 and 1939. These tables are comparable to reports published for preceding years¹ with the exception that, beginning with this report, the basis of the record has become the number of students receiving degrees, rather than the number of degrees granted in the specified period.

Enrollment in Public Health Courses

Number of students enrolled, and Public Health Degrees and Certificates conferred in the years 1938 and 1939 by United States and Canadian Universities. Unless otherwise indicated courses require at least 1 year of residence.

² Diploma in Public Health.

³ In addition to the regular courses, short courses of 1 semester plus 4 weeks' field training period or 12 weeks have been offered through 1938-1939. Seventy-four students registered in 1937-1938 and 38 in 1938-1939. "Certificates of Attendance" were given to 46 students in 1938 and 17 in 1939.

⁴ Short courses only have been offered through 1938-1939. "Academic Awards" for satisfactory completion of courses were given to 35 health officers in 1937-1938 and to 25 in 1938-1939.

⁵ Short courses of post graduate instruction, two each year, each 3 months in length. No degrees or certificates awarded.

Classification of Public Health Degrees and Certificates Granted in 1938 and 1939

Number of persons receiving Degrees and Certificates by reason of public health courses completed:

Public Health Nursing Degrees and Certificates Granted 1937-1938

There were approximately 3,700 nurses studying public health nursing in the programs of study which met certain requirements in regard to theoretical and practical instruction according to the standards of the National Organization for Public Health Nursing. About 2,700 were enrolled during the academic year and 1,000 in summer sessions. Two universities reported enrollments of more than 500 each during the academic year—Wayne and Columbia Universities. Five colleges and universities each reported more than 100 enrolled at summer sessions—the Universities of Michigan, Minnesota, Columbia, Syracuse, and George Peabody.

Of the 2,700 students attending during the academic year, almost half, 46.6 per cent had registered for the first time at the institutions reporting them as 1937-1938 students.

Social security stipends assisted 22.1 per cent of the public health nurses enrolled during the academic year. Of those who received certificates, 23.9 per cent had used social security stipends during the year.

The following table indicates the number of students who received degrees and certificates in Public Health Nursing for this period. These figures have been supplied by the National Organization for Public Health Nursing and are printed here with permission. Note: No report received from Simmons College.

The Educational Qualifications of Health Officers*

THE type of training most desirable for an individual seeking to become a health officer is well recognized. He should have had fundamental training in the sciences and the humanities at least equivalent to that required for a college degree in Arts or Science. He should have completed the course leading to the degree of Doctor of Medicine in a recognized medical school, and should have had at least one year of internship in an approved general hospital, including a communicable disease service. In addition to such internship the candidate should be given a preliminary period of supervised field experience in a well organized department of health for a period sufficient to give him acquaintance with the general aspects of public health, and to give him also opportunity to determine something of his own liking for the work and his fitness for it. At the end of this preliminary field experience the candidate should receive at least one full academic year of graduate instruction in public health in a university. If possible the candidate should have an additional year of practical experience in a subordinate position before becoming himself responsible for the conduct of the work of a department of health.

However desirable so complete a course may be, it is impracticable at this time to insist that all candidates for appointment comply with these require-

ments. In view of this practical situation, some modification may temporarily be made in the direction of recognizing the value of practical field experience obtained under competent supervision as in some measure substituting for formal education.

Certain individuals not possessing a medical degree have achieved success as administrative health officers. It is reasonable, therefore, that the basic training represented by the medical degree, although advisable, need not necessarily be considered absolutely essential in the selection of health officers for jurisdictions where the duties of the health officer are mainly administrative, provided the candidate possesses an adequate general and biological education, has received not less than 2 academic years of graduate instruction in public health, and has had one or more years of administrative experience in some position in a recognized health organization as prerequisite for the duties of health officer.

Because of the unmistakable trend upon the part of governmental bodies to insist upon the medical degree as a prerequisite to appointment as health officer, and because it is impossible to foresee whether the prospective health officer will be located in a health department where his duties are restricted to administrative functions, it is inadvisable to encourage the candidate for a public health degree to look forward to a career as health officer unless he is also the possessor of a medical degree, and for these reasons our recommenda-

* Approved by the Governing Council of the American Public Health Association, October 18, 1939, on recommendation of the Committee on Professional Education.

tions contain no reference to the non-medical health officer.

RECOMMENDATIONS

1. That candidates for appointment as health officer should be graduates of approved medical schools who have completed successfully not less than one year of internship in an approved hospital and in addition a course of not less than one year of graduate instruction in a university, leading to a degree in public health.*

* Where lack of qualified personnel makes it impossible to require a full year of graduate instruction in public health, the postgraduate requirements considered temporarily as applicable for medical health officers for small jurisdictions may be: the satisfactory completion of not less than 3 months of postgraduate instruction in public health in a university, and not less than 3 months of supervised field experience in a well organized health department. Such individuals should be required to complete the course leading to a graduate degree in public health as soon as they have demonstrated ability sufficient to warrant such instruction.

2. That recognition be given to the fact that practical experience in public health administration is an essential part of the education of a health officer, and that great achievement can usually be attained only after long experience. These facts should always be taken into consideration in the selection of health officers, particularly where the position is one of great administrative responsibility.

The above recommendations are made for the future guidance of officials responsible for the appointment of health officers, and for the guidance of individuals looking forward to careers in public health. In making these recommendations the American Public Health Association expressly recognizes the professional standing of persons now performing creditable service as health officers.

Advances in Thiamin Research^{*}

AARON ARNOLD, PH.D., AND F. D. BAIRD

National Oil Products Company, Harrison, N. J.

and

C. A. ELVEHJEM, PH.D.

*Department of Biochemistry, University of
Wisconsin, Madison, Wis.*

THE concerted effort of many research centers has been necessary to evaluate the rôle of thiamin in human and animal nutrition. The fundamental questions which necessarily attend the elucidation of each new nutritional factor continue to receive attention as older methods are made more exact and new ones are introduced. The problems of distribution, stability, quantitative requirements and physiological rôle are receiving serious consideration at the present time.

The chemical estimation of thiamin by the thiochrome procedure¹ which depends on the alkaline oxidation of thiamin with ferricyanide is being used in a number of laboratories. Cerecedo and Hennessy's finding² that zeolite absorbs the vitamin has provided a new approach to the thiochrome assay procedure³ which may obviate earlier difficulties. Melnick and Field⁴ have incorporated the use of zeolite into the colorimetric procedure of Prebluda and McCollum⁵ which is based on the reaction of the vitamin with diazotized p-aminoacetophenone along with xylene extraction and report favorable results

after an extensive series of experiments. Assays on a number of biological materials, after phosphatase treatment, yielded values in accord with previous biological assays. Willstädt and Barany⁶ have obtained promising results with the use of diazotized 2, 6-dichloraniline.

The fermentation methods of Frey, *et al.*⁷ offer possibilities where it is necessary to estimate small amounts of the vitamin. They have refined their method⁸ by determining the thiamin values before and after ferricyanide treatment which destroys only the vitamin. Birch and Harris,⁹ and Baker and Wright¹⁰ have assayed a variety of biological materials for thiamin by the bradycardia procedure with rats. The *Phycomyces* procedure¹¹ may also prove of value under controlled conditions.¹² The organism does not require the intact molecule and its value is thus additionally limited. In this connection it is interesting to note that the Abderhaldens¹³ have found that pigeons are also able to respond to the separate thiazole and pyrimidine components of the thiamin molecule when these are administered in large amounts.

The recognition of new factors in the vitamin B complex and the development of more exact methods for their estimation makes it evident that earlier assays

^{*} Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-eighth Annual Meeting in Pittsburgh, Pa., October 20, 1939.

for thiamin will be revised in many instances. Baker and Wright¹⁰ have supplied extensive tables on a wide variety of food materials assayed with rats by the bradycardia procedure. The findings of Elvehjem, *et al.*,¹⁴ Table 1,

TABLE 1

Recent Values on the Thiamin Content of Selected Foods

Food	Thiamin Content, Dry Basis	
	µg. per gm.	I.U. per gm.
Beef heart	30	10
Beef kidney	15	5

Milk		1.8
Potatoes, boiled and peeled		1.2
White bread (fresh basis)		0.14-0.2
Brown bread (fresh basis)		0.5-0.7
Whole wheat bread (fresh basis)		1.15-1.2
Wheat, whole grain (fresh basis)		1.2-3.4

show that meats may serve as one of the rich sources of thiamin in the diet. As indicated by these investigators, meats may supply up to one-third of the daily requirement for thiamin, even when supplied at a level of 7 per cent in the diet. That meats, particularly when not too well done, may serve as a good source of thiamin is in accord with the observations of Stefansson¹⁵ who recently noted that northern people consuming large quantities of meat never suffer from lack of this factor.

Stiebeling and Phipard¹⁶ have recently completed an extensive survey on the diets of families of employed wage earners and clerical workers in cities. An estimation of the thiamin intake based on the literature values for the foods consumed indicated that all groups

received more than 240 I.U. of thiamin chloride per day estimated in terms of an average man. About half of the families examined received 500 or more I.U. of thiamin chloride per day. Baker, *et al.*¹⁷ have concluded that the best fed members of the English population today, while getting twice as much thiamin as people in the low income group, consume less thiamin than the parish poor of the 18th and early 19th century.

The question of the stability of thiamin has interested investigators in the field for some time. The thiamin contained in cod roe has been reported to be comparatively stable to processing conditions, a loss of only 20 per cent having been observed.¹⁸ Our own studies with dry animal tissues¹⁹ demonstrated that the thiamin contained in these tissues was comparatively stable during a 2 year storage period. The losses of thiamin did not exceed 20 per cent in any of the four tissues assayed.

The evidence on the decrease in thiamin content during cooking is encouraging. Elvehjem, *et al.*,¹⁴ Table 2, studied the effects on meats of frying, roasting, broiling, baking, and stewing. It was found that frying smoked ham, beef round, and pork ham for 15 to 20 minutes did not materially affect the thiamin content. Frying pork loin and veal hindquarter decreased the thiamin content by 35-45 per cent. Roasting, broiling, baking, and stewing decreased the thiamin content by approximately half in the meats studied. It will be noted that the time and temperature involved in these methods of food preparation is longer than that of frying.

The results just mentioned on the vitamin content of processed and cooked meats bear on the results reported by Stiebeling and Phipard.¹⁶ These investigators were aware of this difficulty and estimate that their values are high. The correction factor required to convert

TABLE 2

Stability of Thiamin During Household Cooking Processes

<i>Process</i>	<i>Meat</i>	<i>Processing Time Min.</i>	<i>Destruction of Thiamin Per cent</i>
Frying	Beef round	20	none
	Veal hindquarter	20	45
	Pork ham	15	none
	Smoked ham	15	10
	Pork ham	medium well done	35
<i>Hours</i>			
Roasting	Beef round	2.5	61
	Veal hindquarter	2	58
	Pork loin	1.5	50
Broiling	Beef round	20 min.	50
Baking	Pork loin	1 hr.	50
Stewing	Beef heart	1 hr.	55
	Beef kidney	45 min.	40

their values to the actual conditions cannot be estimated without further data. Baker and Wright²⁰ believe that beriberi may occur on diets supplying 400 or more I.U. of thiamin chloride daily. The protective level according to Baker and Wright may vary according to body weight and food consumption. Harris and Leong²¹ have calculated from Baker and Wright's thiamin values of foodstuffs, as determined by the bradycardia method, that 250 I.U. per day represents the amount of thiamin found in the ordinary middle class dietary in England.

The daily intake of thiamin must therefore be related to the daily requirement in order to utilize the results on the thiamin content of food materials. Stiebelling and Phipard¹⁶ have accepted the earlier values submitted by Cowgill and his coworkers²² and estimate the daily requirement for a 70 kg. man consuming 3,000 calories per day to be 300 I.U. Our own studies with rats, chicks,²³ and dogs²⁴ have indicated that the thiamin requirements of various species may be expressed in a slightly different way. While different criteria may be used for the estimation of minimum vitamin requirements, we have

found that normal growth resulted when the diet of these species was supplemented with 80 to 100 μ g. (micrograms) of thiamin chloride per 100 gm. of low fat diet. The uniformity of results with rats, chicks, and dogs led us to conclude that the human requirement for the antineuritic factor was probably in the same range.

This conclusion is in accord with that of Williams and Spies,²⁵ independently reached as a result of their literature studies on diets borderline to deficient in thiamin as evidenced by actual field observations. On this basis, therefore, the thiamin requirement for a 70 kg. man consuming 3,000 calories or approximately 750 gm. of food should be 600–750 μ g. or 200–250 I.U. of thiamin chloride per day. This level of the vitamin is certainly very close to the minimum and it would be well to supply 2 to 3 times this level. Referring once again to the survey of Stiebelling and Phipard¹⁶ wherein these investigators found that the diets of half the employed workers supplied less than 400 I.U. of thiamin chloride per day without allowance for losses involved during cooking, one may consider that the dietaries of even self-sustaining

families under modern conditions are close to borderline in their content of this factor.

The physiological rôle of thiamin in the body has been studied by a number of workers. Kinnersley and Peters reported in 1929²⁶ that thiamin was associated with carbohydrate and, more specifically, with lactic acid oxidation. Thompson and Johnson demonstrated in 1935²⁷ that the blood of thiamin deficient pigeons contained abnormal amounts of pyruvic acid. This finding was confirmed and extended by Sherman and Elvehjem²⁸ who reported reduced pyruvate oxidation by cerebral and kidney tissue of polyneuritic chicks. Peters in 1936 was led to state that thiamin was either acting as a coenzyme to pyruvic oxidase or constituted the prosthetic group itself. This line of investigation was culminated by the fundamental finding of Lohmann and Schuster in 1937,²⁹ studying the chemistry of the coenzyme for the decarboxylation of pyruvic acid in yeast, that cocarboxylase was thiamin pyrophosphate. Peters, *et al.*³⁰ have recently reported evidence to show that thiamin pyrophosphate is the active principle which gives the catatorulin effect with avitaminous pigeon brain tissue. Goodhart and Sinclair³¹ have reported that the cocarboxylase of the blood is contained entirely within the blood cells which indicates that the readily diffusible form of the vitamin exists either as free thiamin or thiamin phosphate. Elvehjem, *et al.*³² have shown that free thiamin may be distinguished from cocarboxylase in boiled tissue extracts by the proper combination of iodoacetate and fluoride. Lipmann³³ has observed that certain bacteria containing little adenylypyrophosphatase shaken with adenylic acid and pyruvic acid removed inorganic phosphate. This indicated synthesis of adenosinepyrophosphate and, therefore, a linkage between the thiamin and adenylic acid systems

which could supply a new source of energy for phosphorylation.

Evans and Lepkovsky demonstrated in 1928³⁴ that rats fed high fat diets required less thiamin for normal growth than those fed low fat diets. This finding was subsequently confirmed by Salmon and Goodman,³⁵ and Elvehjem, *et al.*^{24, 36} Richter, *et al.*³⁷ have added additional evidence on this point by their technic of free choice experiments. Nine rats on an adequate self-selection diet were rendered deficient in thiamin by the omission of yeast from the diet. At the height of the deficiency, the animals had a marked aversion for carbohydrate and protein, and a craving for fat.

More recently, we have observed in studies with dogs²⁴ that the thiamin requirement may be expressed in terms of the non-fat, energy supplying food-stuffs. Thus, dogs fed low fat diets required 75 μ g. of thiamin chloride per 100 gm. of diet for normal growth. An increase of the fat content of the diet to 56.5 per cent decreased the thiamin requirement of the dogs to 27.5 μ g. per 100 gm. of diet. When the thiamin chloride content of the high fat diet was expressed in terms of the non-fat energy supplying food materials, the requirement was similar to that found with the low fat diet, namely, 75 μ g. per 100 gm. of non-fat dietary constituents. These results are in agreement with the conclusions of Williams and Spies²⁵ who stated that the thiamin sparing action of lard is not due to contained thiamin. This was recently confirmed by Melnick and Field.³⁸ The Michigan workers applied their colorimetric procedure⁴ for thiamin to lard and concluded that it did not contain the vitamin. They were able to recover added thiamin under the same conditions.

These findings have immediate application in that they indicate that the daily requirement in the human dietary

is partly decreased in proportion to the amount of fat supplied by the foods consumed.

Engel and Phillips³⁹ have recently observed that polyneuritic rats cured with crystalline thiamin chloride have abnormal livers as judged by histological examination although no chemical differences could be demonstrated. Polyneuritic animals fed thiamin-low, high fat diets recovered without liver degenerative changes.

The findings of Harris, *et al.*⁴⁰ are important in that they demonstrate quite clearly that the saturation level of thiamin for the rat is readily reached at approximately 10 times (30 I.U.) the requirement level. Examination of the tissues indicated that they were unable to store the vitamin to any extent in contrast to the ability of the body to store the fat soluble vitamins. These investigators report that the urinary excretion of vitamin B₁ may be used as a useful guide for assessing the state of nutrition; a resting level of 10–20 I.U. per day and a response of at least 30 I.U. after the administration of a 350 I.U. test dose may be regarded as indicating normal nutrition.

Perla⁴¹ has made the interesting observation that added amounts of thiamin to a stock colony diet for rats at a level of 30 to 50 I.U. daily resulted in interference with lactation, loss of maternal instinct, cannibalism, and progressive loss of fertility. Sure⁴² has confirmed these observations. No reproduction disturbances resulted⁴¹ when 2 mg. of Mn. (as MnCl₂) daily were added to the diet of the rats parenterally injected with 200 I.U. daily.

Thiamin therapy in human disorders is now being applied on an ever widening front. Recent contributions can only be referred to briefly here. The vitamin has been found effective in cases of hyperthyroidism and tachycardia,⁴³ edemas of nurslings,⁴⁴ intractable pain, and inflammatory and

degenerative diseases of the central nervous system,^{45, 46} chronic diarrheas and atonic constipation,⁴⁷ multiple deficiencies,⁴⁸ and "pernicious vomiting" of pregnancy.⁴⁹

SUMMARY

We may state that the physiological rôle of thiamin in the body has definitely been shown to be associated with the metabolism of pyruvic acid and related keto acids, intermediates in glycolysis. On the basis of studies with laboratory animals, we have suggested that the daily requirement for all species is approximately 1 p.p.m. of low fat dietary solids. This requirement is decreased in the presence of increased amounts of fat in the diet. The requirement must be satisfied by almost constant intake since the body is unable to store appreciable amounts of the vitamin. Studies on the dietaries of middle class families in England and similar groups in this country have indicated the daily thiamin intake is close to the borderline requirement level. A distinction must be made between the requirement level and the optimum level. With the development of simpler and more rapid methods for the determination of the vitamin and new criteria for its function, it will be possible to determine whether the level for optimum nutrition is appreciably above the requirement level.

KENNETH F. MAXCY, M.D.

ARTHUR P. MILLER, C.E.

HARRY S. MUSTARD, M.D.

WALLER S. LEATHERS, M.D., LL.D.

DR. W. S. LEATHERS was made President-Elect of the American Public Health Association at the Pittsburgh meeting in October. At this time, Dr. Edward S. Godfrey, New York State Health Commissioner, became President, and Dr. Abel Wolman, Professor of Sanitary Engineering, Johns Hopkins University, retired as President and was elected Chairman of the Executive Board.

Dr. Leathers was born in Charlottesville, Va. He received his M.A. and M.D. degrees at the University of Virginia; was a student at Johns Hopkins University; did graduate work at Harvard and the University of Chicago; did special research work at the biological laboratories of Woods Hole, Mass., and Cold Spring, N. Y. In 1924 he was awarded the degree of Doctor of Laws by the University of Mississippi, and in 1937 a similar degree from Tulane University.

After serving as Professor of Biology at the University of South Carolina, 1897-1899, he was called to the chair of Zoölogy of the University of Mississippi, where he later was in charge of the Department of Physiology and Hygiene, and in 1904 was made Dean of the Medical Department of the University, which department he organized.

He became Director of Public Health of the State of Mississippi in 1910, and served for 7 years as Director, and 7 years as Secretary and Executive Officer of the State Board of Health. It was Dr. Leathers who brought the health work of the State of Mississippi from obscurity to the point where it

Waller S. Leathers, M.D., LL.D.

attracted not only national attention but the notice of many foreign countries.

In 1924 Dr. Leathers resigned from the Mississippi State Board of Health to accept the position of Professor of Preventive Medicine and Public Health in the School of Medicine of Vanderbilt University, Nashville, Tenn., and in 1928 was made Dean of the School of Medicine, in which capacity he still serves.

Among others, Dr. Leathers is a member of the following societies: American Medical Association, Society of Medical Officers of Health of England, Society of Tropical Medicine, Southern Medical Association, and the American Association for the Advancement of Science. He has been a member of the A.P.H.A. since 1910, is a Charter Fellow and a Life Member, was Chairman of the Committee on Professional Education 1932-1939, and served as a member of the Governing Council 1927-1930, and 1930-1933.

HENRY E. YOUNG, M.D.

WITH the passing of Dr. Young on October 24, 1939, in the 73rd year of his age, the American continent has lost one of its pioneer leaders in public health. We purposely speak of the American continent, for while Dr. Young was a Canadian and his work was done primarily in and for that Dominion, he was one of those rare characters who belong to the world at large and especially to that continent on which he lived and to the betterment of which his activities were largely devoted. While we have enjoyed the fellowship of many of Canada's leaders in public health as members of our Association, Dr. Young, in many ways, came a little closer to us than some others, possibly through his connection with the Western Branch of our Association in which he took a great interest and of which he was President-elect in 1936, when many of us were the recipients of his delightful hospitality at Vancouver and Victoria at a joint meeting of the Canadian Public Health Association and the Western Branch of the A.P.H.A. The occasion was made especially memorable by the presentation of a gavel to the Western Branch, made from the timbers of the S. S. "Beaver," a ship built in 1834 in England, and which for 53 years played a large part in the maritime development of the Northwest Pacific.¹

Dr. Young for 12 years was a Conservative legislator and for 23 years a public servant under six Prime Ministers. During this time he instituted many reforms in the health service of the province. He had a remarkable capacity for organization, the beneficial results of which were always noticeable and especially so during the influenza epidemic in British Columbia in 1918.

One of his great objectives was always the establishment of a University in British Columbia, which was achieved during his lifetime and in which he maintained his active interest to the last. Dr. Young's position in British Columbia was unique in that his services covered three decades during which the governmental attitude toward health and education changed from that of passive direction to active assistance and control, and it is not too much to say that his influence was largely responsible for this change. He was recognized as the dean of public health officers in the Dominion of Canada.

He was always a leader. A brilliant scholastic record at Queen's University and McGill was followed by postgraduate studies at the University of Pennsyl-

vania and in England. Honorary degrees were given him by many universities, including Toronto, McGill, and the University of British Columbia.

Among the offices he held were the Chairmanship and later a Life Member of the Canadian Public Health Association, the Presidency of the State and Provincial Health Authorities of North America, Presidency of the Western Branch of the A.P.H.A. He became a member of the A.P.H.A. in 1916, a Charter Fellow in 1922, and an Honorary Fellow in 1932. He was a member of the National Committee for Mental Hygiene and the American Child Hygiene Association, member of the Honorary Advisory Committee of the Connaught Laboratories, Honorary Vice-President of the St. John Ambulance Association, a Fellow of the Royal Society on Tropical Diseases, a member of the Advisory Council of the Dominion Ministry of Health, an Honorary Fellow of the British Columbia Academy of Science, and member of the Board of Governors of the Canadian Welfare Association.

With his accomplishments as a scientific man and a health officer, he combined a delightful personality, most helpful to the younger men who had the good fortune to be associated with him or to serve under him. It is hardly too much to say that he leaves as many devoted friends and admirers on this side of the border as may be found in Canada, though the people of British Columbia, especially, had the rare privilege of constant association with him year in and year out. Among the great men of whom Canada is justly proud, no one has ranked higher than Dr. Young, and none has commanded greater personal affection and loyalty than he.

THE NEWER VENEREAL DISEASES

WHILE Lymphogranuloma venereum (Lymphogranuloma inguinale) and Granuloma venereum (Granuloma inguinale) doubtless have been with us for many generations it is only comparatively recently that they have been identified as clinical entities. The recognition of these conditions as specific diseases has come about largely by virtue of improved methods for the recognition of syphilis and chancroid, ulcerative diseases long known as effecting the genitalia, and by reason of the development of the Frei test for Lymphopathia venereum and the recognition of Donovan bodies in Granuloma venereum. Without unduly emphasizing the specificity of either of those tests in the diagnosis of the respective diseases, and readily acknowledging the sources of error in either of them, it still must be recognized that often they gave valuable aid in classifying clinical conditions. Health officers concerned with populations which include large numbers of Negroes recognize the great importance of these two diseases as causes of prolonged disability and consequently of great economic loss to the community. It is by no means uncommon for either condition to require months, and even years, of hospitalization at public expense. Our present knowledge of these diseases is just about what our knowledge of syphilis was at the beginning of this century.

The success of efforts to control syphilis is the direct outgrowth of the work of Schaudinn and Hoffman, of Wassermann, and of Ehrlich. Until we have knowl-

edge of the newer venereal diseases comparable to that provided by the investigators mentioned in respect to syphilis we cannot expect much success in attempts to prevent and treat them. Now that our knowledge gained by research has put us in such an enviable position with respect to syphilis as to lead to prospects of speedy success of control measures, let us hope that investigators will devote more attention to these predominantly venereal conditions about which we know so little. Perhaps it would not be expecting too much to desire to see some of the resources in money and energy now going into problems related to syphilis turned into the channels of study of the newer venereal diseases. Such problems as sources of infection, modes of transmission, prophylaxis, and therapeutics all await further study.

A TRIBUTE TO DR. LIVINGSTON FARRAND WHO DIED NOVEMBER 8, 1939

THE Chemin des Dame in 1919 was a strange place in which to develop a friendship. That is where Dr. Farrand and I first had three uninterrupted days together, travelling along the entire Western Front and exploring its devastation. Prior to that our contacts had been in the busy line of duty and our conversations brief. Our voyage together was his first moment of relaxation during or since the World War. Freed momentarily from crushing responsibilities he reacted like a schoolboy and with tireless curiosity darted into dug-outs, examined the remnants of postes de secours, studied maps in an effort to locate vanished villages, slept and ate in the ruins of shattered estaminets, maintaining the while a running fire of keenest question and comment. Now and then on a bit of rising ground he paused in silence, his pitying eyes sweeping that terrain of utter desolation, his great heart suffering at the limitless human tragedy there displayed.

In the twenty years since, during which he has filled many rôles with high distinction, I have always seen him as I knew him then, a boy in spirit, a man in understanding, an alert scholar, a friend of his fellow men. The many sides of his personality were so nicely balanced and so blended with warm human sympathy as to kindle an answering spark of friendship in all his associates.

Life was not ungenerous to Dr. Farrand in its allotment of years. Yet his ceaseless energy and the youthful clarity of his thinking erased from our minds any thought that he was growing old. He had a rare capacity for playing the part of a contemporary with whomever he conferred. That quality endeared him to young and old alike and will abide as a lasting inspiration in the memory of his countless friends.

KENDALL EMERSON

BOOKS AND REPORTS

Man Against Microbe—By Joseph W. Bigger, M.D. New York: Macmillan, 1939. 304 pp. Price, \$2.50.

The writer, who has already established for himself an enviable position as an author of textbooks, now writes for the general public on a subject in which everyone is of necessity interested and which he believes has too long been regarded as a matter only for specialists. He considers microbiology as an educational and cultural subject just as worthy of study as any of the other basic sciences, or even "politics and finance."

One might almost say that the book is dedicated to Antony van Leeuwenhoek, who first saw what we now call bacteria, as it begins with an "Introduction" to him and ends with a tribute to him as "one of the world's few really great men."

The book is orderly arranged in three sections, one giving the meaning of microbiology, the second the history of microbiology, and the third the relation of microbiology to mankind. It is written in simple language and good English which holds the attention of the reader. It is a fascinating story which can be recommended to all laymen whatever their calling.

We have found only one factual error. The author states that Reed, Carroll, Lazear, and Agramonte lived in a well screened hut, using the clothing and bedding, even soiled with the vomit and excreta of those who had died of yellow fever, yet escaped. While the experiment was done under the direction of the American Commission, the man who actually volunteered for this service were Dr. Robert P. Cooke, of

Richmond, Va., Acting Assistant Surgeon, and Privates Levi E. Folk and Warren J. Jernigan. These men deserve all the credit for their heroism and the Commission which planned the experiment gave it to them.

The book is well illustrated with 18 plates and 17 cuts. The plates without exception are good and many of the cuts also. The binding and make-up are excellent.

It is a good book for all public libraries. MAZÏCK P. RAVENEL

Silicosis and Asbestosis—By various authors. Edited by A. J. Lanza, M.D. New York: Oxford University Press, 1938. 439 pp. Price, \$4.25.

Silicosis and asbestosis, diseases quite frequently encountered among workers in certain dusty trades are today regarded as being of real public health significance. Upward of 500,000 workers in the United States are exposed to silica dust to a harmful degree. The present book, representing the joint efforts of 4 American and 2 British experts in this field, is most timely.

Here is summarized the knowledge of both silicosis and asbestosis. The pattern followed conveys the fundamental information in condensed and direct fashion under (1) history, (2) etiology, symptomatology and diagnosis, (3) X-ray diagnosis, (4) pathology, (5) experimental pathology, (6) occupational preventive and legislative aspects in Great Britain, and finally (7) public health and economic aspects in the United States.

In the section devoted to X-ray diagnosis a similar type of tabulation presents the X-ray and histological

appearances in the healthy lung, in simple silicosis, and in silicosis with infection. A discussion of Roentgen Technic includes consideration of time of exposure, focal-spot film distances, type of screens, desired voltage, choice of current, type of tube and the processing of films, measurement of patients, and stereoscopic examinations. This section is very complete and well illustrated.

The sections on pathology (by R. S. Gloyne), and experimental pathology (by L. U. Gardner), taken together present a complete picture of the nature of the damage done by silica dust in man and animals and also a dynamic view of the effect of other dusts on the lungs when mixed with silica dust. This latter portion provides an excellent basis for an appreciation of the effects of various mixed dusts, which constitute a most important medical and compensation problem.

That the incidence of silicosis varies from industry to industry is borne out by a table showing the number of deaths from this disease in Great Britain from 1930 to 1936, the average being 325 deaths per year. This does not represent the true number since many cases are not diagnosed, and while many men have the disease they die from other causes. The nature of the industry, the nature of the dust (its content of free silica), size distribution of dust, concentration, and other factors play determining rôles. Dr. Middleton discusses these points with respect to many different occupations and also prevention and compensation. The British schemes for compensation are well presented.

Dr. Lanza in the final chapter on public health and economic aspects presents the American compensation schemes for silicosis, and a brief discussion of the fundamentals of medical and engineering prevention of silicosis.

LEONARD GREENBURG

The Administration of High School Athletics—By Charles E. Forsythe. New York: Prentice-Hall, 1939. 413 pp. Price, \$2.00.

There is great need of texts written by people with practical experience. This is peculiarly true in the field of education. One of the great weaknesses in education—possibly the greatest—is that so much of our program is instigated by theorists who lack intensive practical experience.

Therefore this text is especially welcome. Written by one who is actually administering interscholastic athletic competition at the high school level, it has a practical point of view.

It is devoted to that special phase of physical education which is called athletics and is applied largely to interscholastic athletic competition. Starting with the history and objectives of such competition, it speaks of the National Federation of State High School Athletic Associations, and of State High School Associations, then discusses regulations controlling eligibility and contests. It discusses policy and administration for local programs, for contest management, and goes on to speak of equipment, awards, finances, and budgets. It discusses the very important basic element of safety and sanitation in athletics, and those things which have so much to do with safety, namely: the facilities for athletics. There is a chapter on intramural athletics which, after all, is the foundation on which a true interscholastic program should be built. It also mentions athletics for girls. The brief discussion of junior high school athletics is not emphasized as much as the reviewer could wish. Great danger rests in interscholastic competition at that age level, where chances of strain and injury are so great.

This text has a great deal of practical information valuable to those who, either from the health viewpoint or

from that of education, have to do with administration at the secondary school level. This is the sort of text that is badly needed in the field of secondary school physical education.

CHARLES H. KEENE

A Girl Grows Up—By *Ruth Fedder*. New York: McGraw-Hill, 1939. 235 pp. Price, \$1.75.

Broad in scope and effectively written, this book meets the test of capturing the interest of the reviewer's 13 year old daughter as well as of other members of the family. Problems of 'teen-age girls and adjustments to be made in growing up—involving decisions in getting along with parents, boys, the world, and themselves—are examined and interpreted in the light of the author's years of experience while working with girls. A useful feature is a list of books you may want to read.

IRA V. HISCOCK

Pulmonary Tuberculosis: A Synopsis—By *Jacob Scgal, M.D.* Oxford University Press, 1939. 150 pp. Price, \$2.75.

This book tells the story of tuberculosis in synoptic form. It is concise and replete with well annotated cuts of roentgenograms illustrating cases taken from the author's own experience. The volume is in 7 divisions, each of which is designed to emphasize the latest advances and most modern concepts in treatment and prevention.

Under General Considerations the author defines pulmonary tuberculosis, describes the sources of infection, modes of spread, and, in simple language, the pathogenesis and pathology of tuberculosis. The second chapter is devoted to a description of the various clinical types of tuberculosis and is illustrated with 3 diagrams showing, respectively, the normal lungs, the active primary complex, and the healed primary complex, followed by

7 very fine reproductions of roentgenograms.

There are chapters on Symptomatology, Complications and Accidents in Pulmonary Tuberculosis, and Diagnosis. The section on Treatment takes up the greater part of the book and is illustrated by 28 reproductions of roentgenograms. In this the author discusses all types of treatment: hygienic régime, medicinal, chemical, physical, biological, surgical, and psychic. The last chapter is devoted to Prevention.

The foreword written by the late Dr. Coryllos states:

It is a truism to say that the education of doctors and students in pulmonary tuberculosis has been neglected in the past and, unfortunately, is being neglected at the present. Patients with pulmonary tuberculosis had been considered as patients to get rid of by sending them away to the country or to sanatoria. But today, our conceptions on the management of the disease have completely changed. Collapse treatment, either by pneumothorax or by more drastic surgical procedures, has transformed this disease into a medico-surgical problem whose solution can be successfully carried out everywhere by the coöperation of the phthisiologist and the thoracic surgeon. However, the fate of the tuberculous patient remains in the hands of the practitioner and depends on his knowledge of the disease and his timely diagnosis.

The publishers are to be commended for the manner in which the roentgenograms are reproduced, one on a page. This increases the size of the book, but adds greatly to its appearance and is attention compelling. The listing of illustrations is descriptive and well conceived. An index is provided. The printing and make-up are good.

The volume is recommended for physicians, medical students, nurses, and health workers. It is a companion to the more elaborate and more detailed texts on pulmonary tuberculosis. It will be welcomed by the profession as a "refresher" textbook.

BERNARD S. COLEMAN

Books and Babies — By Garry Cleveland Myers and Clarence Wesley Sumner. Chicago: McClurg, 1938. 116 pp. Price, \$1.75.

A rare combination of child psychology and intimate knowledge of books suited to the varied ages and interests of young children has gone into the making of this book. The distinguished child psychologist, Dr. Myers, and Mr. Sumner, librarian and founder of the Mothers' Room of the Youngstown Public Library, have written a most interesting and instructive account of the part that the reading of books to children from 2 to 10 may play in the intellectual and emotional development of both the children and their parents.

Services that can be rendered by the library are clearly indicated, though artfully woven into brief accounts of the experiences of the librarian and the parents and children seeking knowledge and adventure in the realm of books.

The book is offered as a "joint effort in behalf of young children and their parents." It affords 2 hours of pleasant, informative reading with many excellent practical suggestions on the guidance and mental growth of the child, and points the way to further values in its field by its many pertinent references to other literature and by a carefully selected bibliography of books and magazines.

FREDERICK W. BROWN

Public Health Law—By James A. Tobey. New York: Commonwealth Fund, 1939. 414 pp. Price, \$3.50.

Rapid expansion of public health activities, including the legal aspects of health administration, during the 13 years since the previous edition, has required considerable expansion and revision of this book, which may be safely recommended for the active use of anyone engaged in public health,

whether administrator, educator, lawyer, or sanitary officer. This modern work on a basic subject reflects the author's wide experience and extensive study, it is written in an interesting style, fully documented, and well printed.

This book is more comprehensive and better arranged than the earlier edition and is the outstanding text in this field. Answers, based on court decisions, are given to many questions. The 21 chapters, supplemented with many references, deal with the law and administration, powers and duties of health departments, liability, legislation, and law enforcement.

IRA V. HISCOCK

Fundamentals of Physical Examination—By George G. Deaver, M.D., B.P.E. Philadelphia: Saunders, 1939. 299 pp. Price, \$2.75.

This book is designed primarily as a textbook or manual for medical students, public health nurses, and physical educators. It is set up with due regard to pedagogical principles with lessons to be written, laboratory work to be carried out, and self-tests at the end of each chapter. The material is laid out systematically with chapters devoted to the special senses and systems of the body with a minimum of words and a goodly number of illustrations. Normal structure and function are described briefly in conjunction with departures from normal. It is encouraging to note that in the chapters on "The Eyes" and "The Ears," the uses of the ophthalmic telebinocular and the audiometer are recommended especially as "screening" instruments in testing school children. It is questionable, however, whether this book should be placed in the hands of physical educators and nurses with the implication that it will equip them to diagnose or treat many of the pathological conditions which are described.

RICHARD A. BOLT

Nutrition and Physical Degeneration: A Comparison of Primitive and Modern Diets and Their Effects—By *Weston A. Price, M.S., D.D.S.* New York: Hoeber, 1939. 431 pp. Price, \$5.00.

This most interesting book is the outcome of study by the author undertaken primarily to determine the cause of dental caries. To this extent the title does not give a fair idea of the compass of the book. The author's thesis may be summed up in the statement that the cause of tooth decay "is controlled directly by nutrition"; that civilization has been anything but a blessing to mankind, and that many primitive racial stocks even in the first generation after the adoption of the modernized diet, and while the blood is still pure, have shown degenerative processes quite like those which characterize America and Europe. He goes further in holding that changes take place in the facial and dental arches, and indeed that accompanying these changes there are many other deteriorative changes in personality and in physical and mental characteristics. He feels that his work is of direct interest to medicine and dentistry as well as to the social organizations concerned with the betterment of racial stock.

His travels have been world-wide. The groups investigated represent a fairly complete cross-section of the racial stocks of the world, Swiss, Gaelics, Eskimos, Canadian and Florida Indians, Africans, South Sea Islanders, Australian Aborigines, Malay tribes, Maori of New Zealand, and South Americans of the Amazon basin and the ancient civilizations of the west coast of that country. Chemical analyses of the foods of some of the isolated groups as well as of those which have displaced them in the process of civilization were made.

The author recognizes that the application of his findings and his con-

clusions are not orthodox, but since our orthodox theories have not saved us it may be necessary to readjust them to bring them into harmony with Nature's laws.

The Foreword by Professor Hooton has a pertinent suggestion along this same line—Why have we been so "stupid" as to concentrate our attention upon finding out why our teeth are so poor and never trying to learn why the teeth of primitive races are good?

The book is a rather remarkable study which covers the primitive racial stocks, both isolated and modernized, of almost every part of the world. Quoting the statement that a good illustration is equivalent to a thousand words, the author gives 6 maps and 134 illustrations, reproductions of excellent photographs. Many of these show comparative pictures of Aborigines who have not yet come into contact with civilization, with the same people who have been "civilized."

No one can doubt the accuracy of Dr. Price's observations or the careful study that he has given to them. His interpretations are open to more criticism but it does seem to be a fact that practically every primitive race which has been studied is largely free from the dental disturbances which affect practically everyone in the so-called civilized countries.

There are some statements which are inexact. For example, the required intake of phosphorus is given differently in different parts of the book—the last amount, 2.64 grams, being high. The amount of iron also is high. On page 265 we are told that the guinea pig is probably the most efficient of animals in synthesizing vitamin D from plant foods. The statement that chlorophyll is the precursor of vitamin A does not seem to be substantiated. We are told also that diabetes is prevented as well as cured by the extract of a plant found in British Columbia.

Other statements require substantiation, and one gathers the impression that the author has accepted some stories as facts without proper verification.

The book goes far to establish what many have already believed—that defective nutrition is the cause of deficiencies which lead to tooth decay as well as to other ills of the human body, of which caries is only one evidence. Whether this is due to deficiency in one substance or several is not known. Instead of putting the blame for caries on one particular type of food, such as carbohydrates, the author believes that we should lay more stress on the lack of some factor, the presence of which is necessary to prevent the untoward action which we now believe to be the cause of caries. He has compiled an impressive volume of evidence to support his contention. The criticisms as to certain facts do not overthrow the mass of evidence that he has collected showing the relation between faulty nutrition and faulty teeth. While the book is very interesting, we consider it also a most important contribution to the understanding of its primary object; namely, the determination of the cause of dental caries. The make-up and printing are excellent.

C. F. ELZEA

Nursery School Education—By Josephine C. Foster, Ph.D., and Marion L. Mattson, Ph.D. New York: Appleton-Century, 1939. 361 pp. Price, \$2.50.

For those who wish information themselves on the subject of the nursery school, or for persons such as doctors, nurses, social workers, or teachers who need to instruct others, scarcely a book could be found with more helpful specific information and suggestions. It is written from a scientific point of view, yet is most practical because backed by years of actual

experience which the authors have spent working in the field of nursery school education.

Usually those who question the value of nursery schools do not know what, as the editor says, "should happen to children who live in a well managed nursery school." In simple, readable language which the lay person can easily understand such subjects as the following are discussed: What is a nursery school? Of what value is nursery school experience for children? What are its objectives? What equipment, what specific methods and technics are considered by authorities in the field of child study as best to use with young children?

The book contains a fine list of references on the subject, as well as many excellent pictures of the activities of young children as found in good nursery schools. It is a splendid source book.

ETHEL GORDON

Handbook on Tuberculosis for Public Health Nurses—By Violet H. Hodgson, R.N. New York: National Tuberculosis Association, 1939. 92 pp. Price, \$.50.

Nurses everywhere will appreciate this compact volume on tuberculosis. The author has drawn on expert opinion in the field and, with a personal background of experience in matters pertaining to tuberculosis nursing, especially from the public health viewpoint, presents information that should be part of the stock-in-trade of every public health nurse.

In addition to chapters of general information about tuberculosis and community relationship, the sections on procedure and technics are preceded by A Concept of Tuberculosis Nursing, which strikes the keynote of relative values in adequate and proper tuberculosis nursing, whether in a generalized or specialized program.

Technics and procedures are de-

scribed succinctly in the sections on Case-Finding, Home Visiting, Nursing Supervision—When and How Long, Substitutes for Home Visiting, Nursing Records, Chest Clinics, What to Teach the Patient and the Family, and Hospital Regimen in the Home. Responsibilities are defined clearly throughout the manual. Attention is also given in respective chapters to the nurse's part in securing hospital care for the patient and the importance of being able to interpret satisfactorily to the patient and family the significance of collapse therapy when indicated. A chapter on Appraisal of the Nursing Service concludes the manual.

The handbook is a worthy successor to Mrs. Hodgson's earlier *Tuberculosis Nursing for Public Health Nurses* and the more detailed manual she produced for the New York State Department of Health. It is very well written and deserves a place in the kit of every public health nurse. It is also valuable for teaching purposes.

BERNARD S. COLEMAN

Health Facts for College Students
—By *Maudc Lee Ethcridge, M.D., Dr.P.H.* (3rd ed.) Philadelphia: Saunders, 1939. 410 pp., 65 ill. Price, \$2.00.

This third edition of *Health Facts* follows the same general plan as the earlier ones, but it has been lengthened somewhat. It deals primarily with problems of personal hygiene. Three chapters are devoted specially to public health practices, namely "Water Supply and Sewage Disposal: Their Relation to Disease," "Diseases Conveyed by Insects," and "Supervision of Public Health." There is a chapter on communicable diseases, and various references to public health problems are found in other parts of the book.

The book aims to present a brief and simple statement of essential health facts. It is written for the most part

in short, simple sentences and avoids technical detail. The reader would enjoy an improvement in the quality of the illustrations. C. E. TURNER

The Newer Knowledge of Nutrition—By *E. V. McCollum, Ph.D., Sc.D., LL.D., Elsa Orent-Keiles, Sc.D., and Harry G. Day, Sc.D.* (5th ed.) New York: Macmillan, 1939. 701 pp. Price, \$4.50.

Twenty-one years have passed since the first edition of *The Newer Knowledge of Nutrition*, and 10 years since the fourth edition appeared, written in collaboration with the present reviewer. In the meantime the field of nutrition has become an indispensable ally of the dentist and the physician, and a potent factor in public health endeavor. Tremendous strides have occurred in studies of the fundamentals of nutrition as well as the ascertainment of requirements for specific nutrients in health and disease. This extended scope of nutrition has required skill in organization and composition, as well as a masterly understanding of the literature, to produce a book which aims, as stated in the preface, to make "... a concise survey of the field of nutrition, which is more extensive and more inclusive than any other now available ..." There is no doubt that the authors have accomplished their objective, and in a simple, attractive style which encourages absorbing interest in the subject.

The first two chapters orient the reader, since they are essentially historical, and trace the development of modern concepts of nutrition. Each of its succeeding 25 chapters is concluded with a list of selected references. An appendix gives tables on the nutritional value of foods as respects vitamins and proteins. The effects of various dietary deficiencies are illustrated.

The authors have presented the

present knowledge of nutrition in a comprehensive manner, including both fundamentals and applications; and there is no doubt that their hope will be realized "... that the book will meet the needs of all who are ... seeking to determine what is sound and what is misinformation in respect to the nutritive needs of the several species including man ... and the means of dealing effectively with these nutritional problems." The book will be a valuable aid not only to nutritionists but to all persons interested in public health. NINA SIMMONDS

Physical Education in the Elementary Grades—By *Strong Hinman*. New York: Prentice-Hall, 1939. 523 pp. Price, \$2.00.

More and more books on physical education are acknowledging the importance of health education. This text is one that indicates that more than just big muscle activity needs to be considered in physical education programs. The author includes what is generally accepted to be the model for school health services. The opening chapters, which deal with the relationships between physical and health education and a modern program of health and physical education, state well what makes up a modern program in the elementary school grades. Inexperienced teachers of physical education would find a great deal of help from such topics as integration and program planning.

More than ordinary thought has been given to including a weekly lesson on health education. However, since the book is primarily a handbook of activities for the elementary grades, one is rather disappointed in not finding more material for the actual integration of health with the physical education program.

The handbook material is nicely divided into story plays, plays set to

music and rhythm for the early grades. Rhythmical activities, folk dances, relays, and athletic games of low organization are carefully graded for the higher elementary years. The final chapters are devoted to conditioning and corrective exercises. Athletic badge tests, and stunts in self-testing activities provide a great deal of material that adds variety and spice to a good physical education program.

D. B. TREAT

The Biology of Bacteria: An Introduction to General Microbiology—By *Arthur T. Henrici, M.D.* (2nd ed.) New York: Heath, 1939. 494 pp. Price, \$3.60.

One is pleased to see a second edition of a book of this informative kind. It indicates that a particular need for such a text is being satisfied and that the subject has progressed sufficiently to justify revision. This edition continues the same interesting and accurate presentation of material which was characteristic of the earlier one, omitting some sections and adding others, as indicated by the development of newer knowledge, such as the work of Karström on constitutive and adaptive enzymes, and the use of sulfanilamide in the treatment of bacterial infections.

Two new chapters on ecology have been added, the first dealing with the effect of environmental factors on bacteria, and the second with the distribution of bacteria in soil, water, milk, and the human body. A summary of Knight's grouping of bacteria on the basis of nutrient requirements and a short discussion of the rapidly developing and increasingly important subject of accessory growth-promoting substances for bacteria has been included in the first of these chapters. Although no attempt has been made to have this include much of the more recent information on the subject, it

should serve to arouse in the student an interest in this fundamental aspect of bacteriology.

The author is to be commended for having presented the subject matter of bacteriology in an interesting manner and in such a way as to emphasize properly the subject as a fundamental biological science, a knowledge of which is so necessary to the intelligent study of its applications. One might hope that, for the future development of bacteriology, such a book would come to the attention of college administrators who still think only of the applications of bacteriology, rather than of the subject as a fundamental biological science.

The volume has been increased in size by 22 pages and has the excellent illustrations and make-up of the first edition. The nomenclature and classification used is in accord with the recent fifth edition of *Bergey's Manual*.

NEWELL R. ZIEGLER

A College Course in Hygiene—
By K. Frances Scott, M.D. New York: Macmillan, 1939. 202 pp. Price, \$2.50.

A reviewer approaches this work with kindly feelings since there is no jacket filled with "blurb" and no letter of recommendation by some supposed authority. "Good wine needs no bush."

For convenience the treatment is in two sections, personal and group hygiene, approximately two-thirds and one-third respectively, each introduced by a "Foreword." The author holds correctly that while the problems of everyday living involve the "entire alphabet of sciences, from agriculture to zoölogy," understanding of the body is fundamental, so the first part gives its structure, functioning, and pathology, while the second considers the emotions and intellect, inheritance, group customs, all the environmental

factors which influence health and measures which may be taken to improve these.

The text is clearly and interestingly written and factually in accord with our knowledge. Most basic topics have sections on the "disorders" and "hygiene" of the organs or functions described which are expected to be supplemented by lectures, discussions, and readings. Suggested readings at the end of chapters are too numerous and many beyond the understanding of the average college student.

The author is Associate Professor of Hygiene at Smith College and the book is addressed to girls. Students are referred to in the text as "she" and "her" though there is good material for men also. Sex is discussed without hesitation in plain language, which is in accord with present ideas.

There is an adequate index. Bound in at the back are 14 leaves called "Workbook," perforated for tearing out and also for loose-leaf binding. The binding is "ring" so that the book lies flat when opened. The printing is clear and the illustrations are well selected. The author has produced a balanced and useful text which can be recommended. MAZÏCK P. RAVENEL

Oh, Doctor! My Feet!—By Dudley J. Morton. New York: Appleton-Century, 1939. 116 pp. Price, \$1.50.

The author of the scholarly and important textbook, *The Human Foot*, has now undertaken to write in a popular vein on foot ailments. His announced purpose of starting people to thinking and talking about their painful and uncomfortable feet is most commendable. There is great need that the public appreciate the importance of comfortably functioning feet, and that foot sufferers learn that ailing feet deserve professional care just as much as any other part of the body.

All the points made are true and important, but are perhaps too technical to be digested by the average individual, unacquainted with the evolution, anatomy, and physiology of the human foot. The material would seem to be over the heads of those whom Dr. Morton is striving to inform and so loses a great part of its educational value.

Dr. Morton stresses the importance of X-ray examination in the diagnosis of foot disorders, and rightly so, but this importance seems overemphasized in a book of this character. The purpose is to encourage the foot sufferer to seek competent advice for relief of his difficulties. Today practically every large store is equipped with an X-ray machine, which is used to demonstrate the fit of the shoe. When we realize how disposed the layman is to believe that an X-ray reveals all that is to be known of his condition, it can readily be seen that many may be misled into thinking that as their feet have been X-rayed by the shoe salesman, he knows all about their foot difficulties, when, in fact, such X-rays reveal nothing except the position of the foot in the shoe. The public has yet to learn that it is not the X-ray shadows which are important, but the interpretation of these shadows.

That section of the book which deals with shoes is excellent. The fallacy of accepting every so-called "orthopaedic shoe" at its face value is clearly shown, and easily understandable suggestions for the selection of a proper type of shoe are given. The chapter devoted to footwear gives a clear guide to the proper clothing of the foot.

While Dr. Morton's contention that all foot discomfort is traceable to "a lazy first metatarsal bone," and all that is necessary for the relief of foot discomfort is that this lazy beggar be made to do its share of the work is open to question, he is to be commended

for his effort to make the public foot-conscious, and for the dignified way in which he has handled a subject which mass lay advertising has made almost a by-word. *Oh, Doctor! My Feet!* can be read with profit by the public, particularly by the parents of growing children, as it will give them much information regarding a very important and much abused part of the body. It may be added that it would make excellent reading for most physicians as well.

FRANK D. DICKSON

Text-Book of Meat Hygiene: With Special Consideration of Antemortem and Postmortem Inspection of Food-Producing Animals--By Richard Edelman, Ph.D. (7th ed. by John R. Mohler and Adolph Eichhorn.) Philadelphia: Lea & Febiger, 1939. 463 pp. Price, \$5.50.

This book has been before the public for a number of years and with the first edition took its place as a standard. The demand for a seventh edition is an index of its value. This revised edition has been brought up to date by changes which make it conform with our most recent knowledge of a pathological conditions which might render meat unfit for consumption.

A new section dealing with the ductless glands has been added, since the hormones extracted from the glands of animals are now being extensively used in the treatment of some conditions of the human body. The Federal Meat Inspection of the United States (Chapter IV) is believed to be the most complete in the world; hence, the editors have incorporated all additions and amendments made to the regulations since the previous edition of this book. For the same reason certain equipment which was figured in the original German publication has been replaced by cuts and descriptions of American apparatus, since the designs are in advance of those formerly used. This particular

apparatus is in use for rendering both the edible and inedible portions of carcasses of animals.

The book is abundantly illustrated and the make-up and printing are excellent. One can say with certainty

that this edition will maintain the high place established by previous ones. As a practical guide as well as reference it can be recommended without reservation.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Vulnerable Teeth—Here in Harpers you will find an excellent article on the teeth and what ails them. The author suggests that some day some enterprising drug house will furnish us with a concentrate of all the essentials that the Eskimo gets in the raw fish and meat that seem to assure him a set of lifetime teeth. Until that blessed event occurs, the author suggests what we may do.

ALVAREZ, W. C. Why Can't We Have Perfect Teeth? Harpers No. 1073, p. 498 (Oct.), 1939.

Hazardous Benzol Fumes—Five fine papers, taking up the entire issue of this magazine as they do, must surely furnish all that health officials will need to know about the hazard of exposure to benzol vapor. This pompous conclusion is based upon a reading of the first three of the 114 fact-filled pages and a glance at the summaries of each paper.

BOWDITCH, M., *et al.* Chronic Exposure to Benzine (Benzol), I. The Industrial Aspects (and four related papers). J. Indust. Hyg. and Toxicol. 21, 8:321 (Oct.), 1939.

Much about Pneumonia—In this symposium, serotherapy, chemotherapy, and general treatment measures are reviewed in detail. Much more of the discussion than one might suppose is of immediate interest to health administrators, for good treatment has prophylactic as well as therapeutic values. So the series is respectfully commended to all health officers.

BULLOWA, J. G. M., *et al.* Serotherapy of the Pneumonias (and three related papers). J.A.M.A. 113, 15:1402 (Oct. 7), 1939.

An Inside Job of Public Relations—How the health department staff can make a real contribution to the school health program is told in practical detail based upon successful experience. In similar vein is discussed methods by which classroom teachers can be induced to take an intelligent interest in health education.

CHOPE, H. D. How Can the Health Department Contribute to the School Health Program? J. School Health. 9, 8:223 (Oct.), 1939.

You Can Make the Horse Drink Water—This prescription for sound health education—select those who can best use it, utilize most effective channels, write clearly and avoid professional lingo, take time to be brief and shun statistics and generalities, tell a good story, and apply the facts to people's problems—is propounded by one who has put it to good effect in teaching mothers and fathers about safe maternity.

CORBIN, H. Teaching the Public About Maternity. Pub. Health Nurs. 31, 11:598 (Nov.), 1939.

Helping to Picture Health Needs—A procedure is proposed by which the actual health problems or accomplishments of a community may be interpreted by a relativity scale which indicates the standing among other communities in any of several indexes.

DERRYBERRY, M. A Procedure for Putting Health Department Reports to Work. Pub. Health Rep. 54, 38:1709 (Sept. 22), 1939.

To Vaccinate or Not—Vaccination with *H. pertussis* vaccine at 6-15 months

of age did not lower the incidence of whooping cough during the following $3\frac{1}{2}$ years when the immunized children were compared to a control group. The attacks may have been somewhat milder.

DOULL, J. A. Active Immunization Against Pertussis. *Am. J. Dis. Child.* 58, 4:691 (Oct.), 1939.

How to Immunize against Diphtheria—A brief but dramatic account of Ramon's discovery of anatoxine enlivens this rather detailed discussion of the prophylactic values of the various toxoids. But at the end is this whooping schedule for infant pincushions: 3-6 mos., smallpox vaccination; 6-8 mos., whooping cough; 9-12 mos., diphtheria toxoid; 18 mos., reinforcing whooping cough vaccine; 1-2 yrs., scarlet fever toxin; 2-4 yrs., reinforcing dose of toxoid; and 5-10 yrs., a repeat smallpox vaccination. At the end it is suggested that somewhere in the schedule a shot of tetanus and some typhoid fever inoculations would add to the gaiety of the child's life.

FRASER, D. T. Diphtheria Toxoid. *Canad. Pub. Health J.* 30, 10:469 (Oct.), 1939.

Historical Note—In this graphic account of the devastation resulting from an invasion of yellow fever into a quiet peaceful college community, the health publicist will find some excellent material on which to try his craftsmanship. A first-hand account of the last yellow fever epidemic is a jewel of the first water.

HERRICK, G. W. The Last Epidemic of Yellow Fever. *Sci. Month.* 49, 5:401 (Nov.), 1939.

Treatment for Early Syphilis—Massive doses of arsphenamine given on succeeding days by a continuous administration method are reported as producing immediate results and serological cures in most early cases. Warning is given that massive dose therapy

is still in an experimental, though promising, stage.

HYMAN, H. T., *et al.* Massive Dose Therapy of Early Syphilis by the Intravenous Drip Method. *J.A.M.A.* 113, 13:1208 (Sept. 23), 1939.

Counting Sheep Now Passé—What will our vitamins cure next? It seems that vitamin B and ascorbic acid may help prevent insomnia, especially in old people and alcoholics.

KARNOSH, L. J. The Treatment of Insomnia. *J.A.M.A.* 113, 14:1322 (Sept. 30), 1939.

Family Size and Income—When we glibly view-with-alarm the failure of "the best" people to produce their quota of children, we must first be sure we know what we are talking about. If we base fertility rates on *all* women, the generalization that the better off they are, the fewer the children they have, is true; but if *married* women alone are considered, there is more nearly an equality in fertility rates among those who have sufficient family incomes and those who have not.

KARPINOS, B. D., and KISER, C. V. The Differential Fertility and Potential Rates of Growth of Various Income and Educational Classes of Urban Populations in the United States. *Milbank Quart.* 17, 4:367 (Oct.), 1939.

More about Pneumonia—Here in a half dozen pages is set forth all that health workers generally will need to know about the newer methods for the treatment of pneumonia. They will learn that chemotherapy, as effective as it has proved to be, does not relieve them from their educational responsibilities. Pneumonia, the public must be told constantly, is still a medical emergency that needs prompt and immediate care; typing is still vitally important, so laboratory services must be maintained for, in appropriate cases, serum therapy should be combined with chemotherapy.

LORD, F. T. Chemotherapy and Sero-therapy of Pneumonia. *New Eng. J. Med.* 221, 15:570 (Oct. 12), 1939.

Where Air Sirens Wail—Here's hoping that we, hereabouts, will never have more than an academic interest in these two papers concerning air raid precautions which, in England, are organized under the Ministry of Health, which turns over to the local health official the responsibility for administration in his community.

MURCHIE, F., and BRUCE, C. R. Medical Air Raid Precautions (two papers). *J. Roy. Inst. Pub. Health & Hyg.* 2, 10:599 (Oct.), 1939.

Nursing Contributions to Child Health—Most of the time of the school nurse should be spent, not in school, but in the homes of the children, educating parents. Usually most of her working day is taken assisting in physical examinations or teaching health in classrooms rather than teaching teachers, or helping the individual children who need guidance. Remedies are considered.

ROSS, G. The Nurse's Contribution to the School Health Program. *J. School Health.* 9, 8:236 (Oct.), 1939.

In Place of Hog and Hominy—If we substitute nicotinic acid therapy

for adequate southern diets, some other deficiency disease will probably replace pellagra as a public health problem. Dietary guidance and the stimulation of kitchen gardens are what the south needs most.

SEBRELL, W. H. The Nature of Nutritional Diseases Occurring in the South. *Milbank Quart.* 17, 4:358 (Oct.), 1939.

About Communicable Diseases—Brief, but very much to the point, is this resumé of the present status of our knowledge about scarlet fever, diphtheria, meningitis, whooping cough, mumps, measles, and poliomyelitis. The forty references in the bibliography should give the epidemiologist plenty of mental ammunition.

WESSELHOEFT, C. Contagious Diseases. *New Eng. J. Med.* 221, 17:655 (Oct. 26), 1939.

Preventable Cancer Deaths—In New York City 15 per cent of all deaths were due to cancer. A large number of the 11,160 cancer fatalities might have been prevented. Here is a challenge which is discussed from a dozen different angles to make a most useful health educational symposium.

WOOD, F. C., *et al.* The Need for Educating the Public on Cancer (and other papers). *Neighborhood Health (N. Y. City).* 5, 6:1 (Nov.), 1939.

ASSOCIATION NEWS

THE SEDGWICK MEMORIAL MEDAL

Excerpt from the citation of Thomas Parran, M.D., who was awarded the Sedgwick Memorial Medal "for distinguished service in public health"

Milton J. Rosenau, M.D., *Chairman of the Sedgwick Memorial Medal Committee:*

"Public health in this country is fortunate in having at the helm a pilot who steers a clear course toward a health haven called health heaven. Dr. Thomas Parran, our Surgeon General, is a rare combination of sanitary statesmanship with a sound foundation

"It is my personal pleasure and official duty to award him the Sedgwick Memorial Medal for services to humanity with this citation:

"Courteous in thought and act, courageous in plan and execution of new concepts for the public good, precise and consistent in the conduct of the affairs of science as in the offices of the government, Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service and Past-President of The American Public Health Association, to whom the Sedgwick Medal is now awarded, has endeared himself to his professional colleagues by his personal modesty in the midst of national acclaim and distinction, and to all who know him and know of him by his ringing challenge to action against the inertia and indifference of the generations to neglected human health. We rejoice in your honors and share in universal confidence in your leadership in public health."

Thomas Parran, M.D.

of experience in the practice of our art and a firm knowledge of the science that underlies good health administration. Dr. Parran has a fine feeling for the socially unfortunate and is ever ready to give a helping hand to the under-privileged.

Response of Dr. Parran:

"I am honored to receive at your hands, Dr. Rosenau, this symbol commemorating the name of Dr. Sedgwick, the great pioneer in public health.

"At this time also, I feel it particularly appropriate that we should be reminded of a passage in Dr. Sedgwick's presidential address before this Association, 24 years ago, as we stood aghast before the first World War. He said:

"It may seem to some as if, under the shadow of a war characterized as never before by the destruction of life, efforts for saving life through hygiene and sanitation must be of small matter.

"But it is not so. After the clouds, the sun. And we believe that after the present bloody conflicts are ended . . . the eternal principles underlying the nobler pursuits of Life, Liberty, Health and Happiness will once more move and inspire the nations as sunshine warms and quickens the earth after a storm. Meantime, we must prepare for active and intelligent dealing with the thousand new and mighty problems which these

wars are certain to bring before us, and to this task we turn with cheerful courage.'

"Even more than in 1915, it is important that we should be aware of what is in the world about us, yet refuse to be overwhelmed by it.

"For my part, and for those associated with me, may I say that we shall give all that we have of effort and devotion that the high traditions of the search for new knowledge and its application to the saving of life may go forward here in America though in other nations of the earth it may be swept aside."

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers

- Daniel Bergsma, M.D., 1671 Pennington Road, Trenton, N. J., Medical Assistant, Venereal Disease Control, State Dept. of Health
 Alvin R. Clauser, M.D., M.S.P.H., District Health Office, Los Lunas, N. M., Health Officer, Dept. of Public Health
 Bert H. Malone, M.D., C.P.H., Box 23, Waycross, Ga., Regional Medical Director, State Dept. of Health
 Charles E. McPartland, M.D., 29 S. Main St., West Hartford, Conn., Health Officer and Registrar of Vital Statistics
 Gilbert P. Pond, M.D., 1140 Lake St., Oak Park, Ill., Commissioner of Health

Laboratory Section

- Abraham Cantor, M.A., Laboratories of Public Health and Preventive Medicine, Univ. of Pennsylvania, Philadelphia, Pa., Instructor in Bacteriology
 Herbert M. Smith, M.D., State Board of Health, Columbia, S. C., Director, Hygienic Laboratory

Vital Statistics Section

- Frances M. James, M.A., 5304 New Hampshire Ave., N. W., Washington, D. C., Statistical Research Division, Children's Bureau

Engineering Section

- William J. O'Connell, Jr., 171 2nd Street, San Francisco, Calif., Technical Expert and Sanitary Engineer, Wallace & Tiernan Co., Inc.
 Thomas M. Sperbeck, A.B., 2810 Oakland Ave., Nashville, Tenn., Trainee, Vanderbilt University

Industrial Hygiene Section

- E. M. Adams, Ph.D., 501 E. Grove St., Midland, Mich., Industrial Hygiene Research, Dow Chemical Co.
 Robert H. Flinn, M.D., National Institute of Health, Bethesda, Md., Passed Assistant Surgeon, U. S. Public Health Service
 Augustus F. Galloway, M.D., Room 301, State House, Boise, Idaho, Director of Industrial Hygiene, State Division of Public Health

Food and Nutrition Section

- Mabel R. Stimpson, B.S., C.P.H., 203 N. Wabash Ave., Chicago, Ill., Nutrition Supervisor, Infant Welfare Society of Chicago

Maternal and Child Health Section

- Robert C. Hood, M.D., Children's Bureau, Washington, D. C., Director, Crippled Children's Division

Emily L. Ripka, M.D., M.P.H., Michigan Dept. of Health, Lansing, Mich., Regional Consultant, Bureau of Maternal and Child Health

Public Health Education Section

Paul W. Barenberg, A.B., C.P.H., 222 Cabot St., Beverly, Mass., Executive Secretary, Essex County Health Assn.

Dorothy R. Denniston, M.A., 69 Henry St., Binghamton, N. Y., Executive Secretary, Broome County Tuberculosis and Public Health Assn.

Elizabeth M. Kiewer, R.N., 1211 Harvard, Fresno, Calif., Director of Indian Welfare, Fresno County

Philip M. Law, M.D., 706 S. Wolcott St., Chicago, Ill., Director, Division of Mental Hygiene, Univ. of Loyola

Catherine F. Smulling, R.N., 212 S. Allen St., State College, Pa., Public Health Nurse, American Red Cross

Elizabeth A. Taylor, M.D., Box 3837, Denton, Tex., Physician and Director of Health Service, Texas State College for Women

Elmo W. Tucker, D.M.D., 430 Rialto Bldg., Butte, Mont., Orthodontist

Public Health Nursing Section

Hilda M. Brandt Carlson, 2917 West 76th St., Los Angeles, Calif., School Nurse, Los Angeles Board of Education

Marie E. Smith, R.N., Box 1124, Grants, N. M., Public Health Nurse, Valencia County Health Dept.

Grace M. Tubbs, R.N., 213 E. 9th St., Winfield, Kans., Visiting Nurse, Winfield Public Health Nursing Assn., Inc.

Frances D. Williams, 420 State Office Bldg., Denver, Colo., District Orthopedic Nurse, Division of Public Health Nursing, State Dept. of Health

Epidemiology Section

Joseph A. Bell, M.D., C.P.H., National Institute of Health, Rockville Pike, Bethesda, Md., Passed Assistant Surgeon, U. S. Public Health Service

Thomas D. Dublin, M.D., 440 West 34th St., New York, N. Y., Physician-in-Training, State Dept. of Health

Carl C. Dudley, Health Dept., City Hall, Houston, Tex., Food and Sanitary Inspector

Ira C. Miller, M.D., 2711 Logan St., Camp Hill, Pa., Epidemiologist, State Dept. of Health

James Watt, M.D., Dr.P.H., Box 111, Albany, Ga., Assistant Surgeon, U. S. Public Health Service

Stafford M. Wheeler, M.D., New York State Health Dept., Albany, N. Y., Assistant in Epidemiology and Preventive Medicine, Harvard Medical School (on leave of absence)

Unaffiliated

Charles L. Ianne, M.D., Santa Clara County Hospital, San Jose, Calif., Director, Bureau of Tuberculosis, Santa Clara County Health Dept.

H. Allen Moyer, M.D., State Administration Bldg., Lansing, Mich., State Health Commissioner

ELECTION OF TEN FELLOWS TO THE GOVERNING COUNCIL

THE nomination of 30 Fellows, carefully cosen for their Sectional affiliation and their geographic distribution by the Nominating Committee, has been noted in these columns. At the 68th Annual Meeting in Pittsburgh, October 17-20, 451 Fellows were registered, or 42 per cent of the Fellowship entitled to vote. Of the 262 ballots cast, 28 were disqualified by the tellers, leaving 234 qualified ballots. The following 10 Fellows were elected members of the Council for a 3 year term, expiring in 1942:

J. N. Baker, M.D.

Karl F. Meyer, Ph.D.

Harry S. Mustard, M.D.

George H. Ramsey, M.D.

W. S. Rankin, M.D.

Robert H. Riley, M.D.

L. R. Thompson, M.D.

W. Frank Walker, Dr.P.H.

Robert E. Wodehouse, M.D.

Hans Zinsser, M.D.

The Governing Council was advised of the election of Dr. James P. Leake of Washington as Chairman of the Epidemiology Section, which carries with it membership on the Governing Council. Dr. Dean Franklin Smiley of Ithaca, N. Y. was declared elected to the Council for the unexpired term of Dr. Leake, ending in 1941, since he had the next highest number of votes in the balloting.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, when keyed, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y., identifying clearly the key number on the envelope.

POSITION AVAILABLE

State department of health wishes to employ a physician trained in statistical work. Salary to begin not less than \$3,000. W442

POSITIONS WANTED

ADMINISTRATIVE

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; is available as venereal disease control officer. A363

Physician, M.D., Vanderbilt University; Dr.P.H., Johns Hopkins; experienced as epidemiologist, health officer and professor of preventive medicine, seeks position as administrator or epidemiologist. A397

Physician, M.P.H., Harvard; well experienced in city and rural health administration, will consider appointment as district health officer or in city or state health department. A418

Well qualified physician, M.D., Rush; M.S.P.H., University of Michigan; with 3 years' residence in tuberculosis, and special interest in venereal disease control, seeks responsible appointment. Excellent references. A406

Physician, 32, M.D., 1936; postgraduate course in venereal disease control, experienced as district health officer and in organizing and publicizing syphilis control campaign; now employed in charge v.d. clinics in metropolitan health department; seeks v.d. control post with opportunity to organize or administer program. A437

Physician, with C.P.H. from Johns Hopkins, and some field experience with large state health department, wishes position in epidemiology or administration. A443

Physician, M.D., class A medical school; 12 years' full-time public health experience; now employed with state department of health; will consider opening with well organized city or state department in communicable disease division, or epidemiology, or both. A409

Physician, M.D., Syracuse University; postgraduate studies in bacteriology and immunology, will consider position as health officer or epidemiologist. Has served as director of county health unit, director of industrial hygiene and medical statistics and venereal disease field survey officer. A305

HEALTH EDUCATION

Well qualified woman in health education wishes position as director of health education or health counselor. Has wide experience, and Ph.D. from New York University. H236

Experienced teacher in public health and author; M.A., Columbia; experienced in teaching public health nursing and carrying field promotion, wishes broad opportunity to train field personnel in extending knowledge and interest to the general public, especially through group education, institutes, exhibits and rural programs. H400

LABORATORY

Experienced teacher in bacteriology and public health; Ph.D., Cornell; now professor in grade A medical school, will consider teaching, executive or administrative position. M437

Experienced teacher in bio-chemistry and bacteriology; Ph.D., Iowa; now laboratory director in midwestern state; will consider teaching, executive or administrative position. L440

Young woman bacteriologist, M.A., Columbia; experienced in bacteriology, serology, mycology, parasitology, water and milk analysis, and general public health laboratory work; seeks responsible position in laboratory work or teaching of bacteriology. L444

MISCELLANEOUS

Engineer with good training and experience in water treatment, sewage plant operation and in research, wishes position as superintendent. Can go anywhere. E422

Positions Open

COUNTY HEALTH OFFICERS—Several for rural districts in South; men under 35 required unless they have public health training or experience; training provided for young men now completing internship, or with general practice experience; southerners preferred. PH-120, Medical Bureau, Palmolive Building, Chicago.

STAFF PHYSICIAN—California sanatorium; physician with 2-3 years' training in tuberculosis, qualified to do minor lung surgery; \$210, increasing. PH-121, Medical Bureau, Palmolive Building, Chicago.

WOMAN PHYSICIAN—Qualified for appointment in division of Maternal and Child Health; state department of health; South. PH-122, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH PHYSICIAN—Young man or woman whose training has been primarily in internal medicine; exclusive college for women; mid-south. PH-123, Medical Bureau, Palmolive Building, Chicago.

SUPERVISOR—Graduate nurse qualified to supervise city-county public health unit; must have public health certificate, popular southwestern winter resort. PH-124, Medical Bureau, Palmolive Building, Chicago.

SUPERVISOR—Well-established public health nursing association; duties include directing staff of nine in bedside nursing program; fairly large city, 2 hours' drive from New York. PH-125, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—For supervising position, county health department; considerable public health experience required; \$1,600, increasing; \$500 travel expenses; midwest. PH-127, Medical Bureau, Palmolive Building, Chicago.

CLINIC SUPERVISOR—Must have certificate or degree in Public Health Nursing; \$125; Texas. PH-128, Medical Bureau, Palmolive Building, Chicago.

STUDENT HEALTH NURSE—Duties largely general duty in college infirmary; \$100, meals; junior college for women. PH-129, Medical Bureau, Palmolive Building, Chicago.

BACTERIOLOGIST-SEROLOGIST—City laboratory; \$1,800-\$2,000; midwest. PH-130, Medical Bureau, Palmolive Building, Chicago.

SENIOR TECHNICIAN—Public health laboratory; must be thoroughly trained bacteriology, tissues; public health experience required; \$150; vicinity New York City. PH-131, Medical Bureau, Palmolive Building, Chicago.

Situations Wanted

PUBLIC HEALTH PHYSICIAN—Young man with M.S. in Public Health from university offering excellent course; unqualified recommendations from executives in public health field; for further information please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

PUBLIC HEALTH NURSE—B.S. and graduate nurse degree, state university; one year's post-graduate training in public health nursing; several years' teaching experience; 2 years, supervisor, medical clinics, university hospital; for further information, please write M. Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

YOUNG WOMAN PHYSICIAN—Extensive graduate training in pediatrics; 4 years, child hygiene division, state health department; several years, private practice pediatrics; wishes to return to full-time public health work; for further information, please write M. Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

BACTERIOLOGIST—B.S., eastern school; C.P.H. and Ph.D. (Bacteriology), Yale University; has done considerable research; 4 years, bacteriologist and research technician, public health laboratories; for further details, please write M. Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

NEW AFFILIATED SOCIETIES, A.P.H.A.

THE Idaho Public Health Association and the Tennessee Public Health Association were elected as Affiliated Societies of the American Public Health Association at the Pittsburgh meeting in October, making twenty-one Affiliated Societies in all at the present time.

SOCIAL HYGIENE DAY

NATIONAL Social Hygiene Day, an annual American public health event, will be observed for the fourth time on February 1, 1940, it has been announced by the American Social Hygiene Association.

RADIO PROGRAMS

THE United States Office of Education, a part of the Federal Security Agency, has announced a series of educational radio dramas on Democracy in Action relating to the United States Government and health. Beginning in November, the last three programs will be given Sunday afternoons, December 3, 10, and 17, from 2:00 to 2:30 P.M., Eastern Standard Time, over the Columbia Broadcasting System.

The topic of the first of these programs is "If the Truth Be Known," an attack on disease through the microscope and test tube; the second, "A New Lease on Life," the story of Uncle Sam's special patients; the third, "Partners in Prevention," a review of national, state, and local agencies and their battle for health.

BARNARD TO ESTABLISH HEALTH EDUCATION PROGRAM

A HEALTH educational program for Barnard College, New York, has been announced. It will be called the Milbank Anderson Health Education Fund, in honor of Mrs. Anderson, who presented Milbank Hall and Quadrangle to the college.

WHITE HOUSE CONFERENCE

IT has been announced by Miss Katharine F. Lenroot, Chief of the Children's Bureau and Executive Secretary of the White House Conference on Children in a Democracy, that President Roosevelt approves the recommendation of the Planning Committee of the White House Conference for the meeting dates January 18, 19, and 20, 1940.

This White House Conference, which had its first meeting on April 26, 1939, in Washington, has as its purpose to consider the relationship between a successful democracy and the children who form an integral part of the democracy. A report committee has under preparation a report to be submitted at the conference, together with suggestions for a follow up program.

MICHIGAN PUBLIC HEALTH ASSOCIATION

THE Michigan Public Health Association held its 19th Annual Public Health Conference, in coöperation with the Michigan Department of Health, at Grand Rapids, November 8-10. More than a thousand members of the health professions attended the three day sessions.

The following new officers were elected for the forthcoming year:

President—Henry F. Vaughan, Dr.P.H.
President-Elect—Floyd R. Town, M.D.
Vice-President—Lena Schermann, R.N.
Secretary-Treasurer—Marjorie Delavan
Representative on A.P.H.A. Governing Council—John L. Lavan, M.D.

Among the principal speakers were: Dr. H. Allen Moyer, Commissioner; Surgeon C. C. Applewhite, of the U. S. Public Health Service; Dr. Burton R. Corbus, President of the State Medical Society; Dr. Paul H. Jeserich, President of the State Dental Society; Dr. Bert I. Beverly, of Chicago; and Dr. S. David Kramer, Secretary of the

National Foundation for Infantile Paralysis.

Holding their annual meetings in conjunction with the conference, were the Michigan School Health Association, The Michigan State Association of Sanitarians, the State Organization for Public Health Nursing, and the Children's Fund of Michigan.

The Michigan Public Health Association, at its annual business meeting, voted to hold its 1940 meeting at Detroit, in conjunction with the annual meeting of the American Public Health Association which will be held there next year. The association also voted to award all of its past presidents honorary keys, symbolic of their services to the association.

AMERICAN SCHOOL HEALTH ASSOCIATION

NEW officers elected by the American School Health Association in Pittsburgh, Pa., October 18, include:

President, Dr. Charles L. Outland, Richmond, Va.

President-Elect, Dr. Amos L. Beagler, Denver, Colo.

Vice-Presidents, Dr. James F. Rogers, Washington, D. C., and Dr. Helen Ahrens Cary, Portland, Ore.

Executive Secretary, and Treasurer, Dr. A. O. DeWeese, Kent, Ohio

CONFERENCE OF MUNICIPAL PUBLIC HEALTH ENGINEERS

AT the meeting of the new society, the Conference of Municipal Public Health Engineers, held in Pittsburgh in October, the following officers were elected:

Chairman—Joel I. Connolly, Chicago, Ill.
Vice-Chairman—Aimé Cousineau, Montreal, Que., Can.

Secretary-Treasurer—Alfred H. Fletcher, Memphis, Tenn.

Executive Committee—F. Gardner Legg, Detroit, Mich.; Henry C. Lane, Pensacola, Fla.; James L. Barron, Hempstead, N. Y.; Arthur E. Gorman, Chicago, Ill.; William T. Ingram, Stockton, Calif.; Sol Pincus, New York, N. Y.

INTERNATIONAL SOCIETY OF MEDICAL HEALTH OFFICERS

NEW officers elected by the International Society of Medical Health Officers, elected in Pittsburgh, Pa., October 18, include:

President, Dr. Leon Banov, Charleston, S. C.

Vice-Presidents, Dr. James Roberts, Hamilton, Ont., and Dr. Angel de la Garza Brito, Mexico City, Mexico

Secretary, Dr. I. C. Riffin, Richmond, Va.

Directors, Dr. N. A. Upchurch, Jacksonville, Fla.; Frederick D. Stricker, Portland, Ore., and Dr. A. T. McCormack, Louisville, Ky.

THE ORAL HEALTH GROUP

THE Oral Health Group, an informal assembly of those in the American Public Health Association interested in oral health, again held sessions at the Annual Meeting in Pittsburgh in cooperation with several of the Sections. The Oral Health Group has elected the following officers for the coming year: Richard W. Leonard, D.D.S., Chief, Division of Oral Hygiene, Maryland Department of Health, Baltimore, *Chairman*; and J. M. Wisan, D.D.S., Dental Health Consultant, New Jersey Department of Health, Trenton, *Secretary*.

PENNSYLVANIA PUBLIC HEALTH ASSOCIATION

NEW officers elected by the Pennsylvania Public Health Association, on October 18, in Pittsburgh, Pa., are:

President, Harold F. Keller, Philadelphia
President-elect, Dr. Paul A. Keeney, Harrisburg

First Vice-President, Dr. Richard P. Lienhardt, Wayne

Secretary-Treasurer, C. E. Houston, Washington

Executive Board, Dr. James R. Smith, Erie; Arthur M. Dewers, Philadelphia; Dr. Henry Field Smyth, Sr., Philadelphia; Dr. J. Moore Campbell, Harrisburg, and Dr. W. W. McFarland, Pittsburgh

The 1940 meeting will be in Philadelphia.

TRI-STATE CONFERENCE OF FOOD AND HEALTH OFFICIALS

NEW officers elected by the Tri-State Conference of Food and Health Officials, on October 18, in Pittsburgh, Pa., include:

President, Dr. Reece M. Pedicord, Wheeling, W. Va.

Vice-President, Elmer E. Harter, Harrisburgh, Pa.

Second Vice-President, Charles M. McDonald, Akron, Ohio

Third Vice-President, Howard Patton, Pittsburgh, Pa.

Secretary-Treasurer, Thomas W. Henderson, Washington, Pa.

The winter conference will be held in Pittsburgh, in January, 1940.

STATE DIRECTORS OF LOCAL HEALTH SERVICE

THE initial meeting of the newly organized Conference of State Directors of Local Health Service was held in Pittsburgh, Pa., on October 16, at the time of the American Public Health Association annual meeting.

The Conference was organized with Dr. John Williams, Jr., Director of the Division of Local Health Administration, Jefferson City, Mo., as Secretary, and Dr. Marvin F. Haygood, Deputy Commissioner and Director of Local Health Service, Iowa State Department of Health, Des Moines, as Chairman.

ILLINOIS DISTRICT HEALTH UNITS

IT is announced by the Illinois State Department of Public Health, Springfield, that 19 district health units have been established, with another in prospect, rounding out the permanent working machinery of the department in the field.

Each unit embraces from two to seven counties, is in charge of a medical health officer who has had at least a short course in public health administration at a recognized school of public health, and has a minimum staff of a

public health nurse, a sanitary engineer, and a secretary. The function of these units is to promote the development of local health services and to render local health service in areas where no local machinery is available.

EUROPEAN JOURNALS AND THE WAR

THE American Documentation Institute requests that subscribers to European chemical or other scientific journals who do not receive their copies report the matter promptly. The Cultural Relations Committee of the Institute hopes to be able to surmount such war obstacles as interrupted transportation, embargoes, and censorship, which seriously affected the progress of research during the last war. It is hoped that the principle will be established that materials of research having no relation to war shall continue to pass freely, regardless of the countries of origin or destination.

Reports with full details of where subscription was placed, name and address of subscriber, volume, date and number of last issue received, should be sent to: American Documentation Institute, Bibliofilm Service, U. S. Department of Agriculture Library, Washington, D. C.

REORGANIZATION OF LABORATORY DIRECTORS' CONFERENCE

A REORGANIZATION of the Conference of State Laboratory Directors was effected at its 19th Annual Meeting in Pittsburgh on October 16, when a Constitution and By-Laws was adopted changing the name and expanding the organization into a Conference of State and Provincial Public Health Laboratory Directors with full membership privileges limited to directors of official state and provincial public health laboratories. The committee on reorganization which proposed the constitutional changes was composed of

the following members representing laboratories widely scattered geographically throughout the United States and Canada:

E. M. Bramhall, Utah
L. F. Ey, Ohio
Mac H. McCrady, Quebec
C. A. Perry, Sc.D., Maryland
E. S. Robinson, M.D., Massachusetts
T. F. Sellers, M.D., Georgia
H. J. Shaghnassy, Ph.D., Illinois
A. B. Wadsworth, M.D., New York
Friend Lee Mickle, Sc.D., Connecticut,
Chairman.

Associate membership was made available to the responsible assistants of directors of state and provincial laboratories and to the directors and responsible assistants in municipal and other official public health laboratories in the two countries.

In the newly adopted Constitution it is stated that the purposes and objects of the Conference shall be to promote the development, improvement, and effectiveness of public health laboratory service; to coördinate public health laboratory activities; to stimulate the interchange of experience among directors of official public health laboratories; to develop and maintain adequate standards for the professional training of public health laboratory personnel; to encourage constant effort toward the improvement and standardization of technical methods; to collect and make accessible to all persons in official administrative positions in public health laboratories such information and data as might be of assistance to them in the proper fulfillment of their duties.

It is proposed in the By-Laws that the Conference continue to meet annually at the place of the Annual Meeting of the American Public Health Association and on the day preceding the opening date. Scientific and business meetings open to the entire membership have been provided for, as well as executive sessions limited to full

members for action on matters of policy affecting state or provincial public health laboratories. The Conference will continue issuing annually a mimeographed volume of Proceedings which will be furnished to members and sold to other interested persons as in the past.

The officers and councillors elected for 1939-1940, all directors of state laboratories, are:

Chairman, Friend Lee Mickle, Sc.D., Connecticut

Vice-Chairman, L. F. Ey, Ohio

Secretary-Treasurer, Katherine E. Cox, West Virginia

Councillors, T. F. Sellers, M.D., Georgia;
E. S. Robinson, M.D., Massachusetts

ALCOHOLISM

A BROAD program for attacking the disease of alcoholism and the alcoholic psychoses, based on research, was approved by the newly elected executive committee of the Research Council on Problems of Alcohol, an associated society of the American Association for the Advancement of Science, according to an announcement by the committee's chairman, Dr. Karl M. Bowman, Director of Psychiatry, Bellevue Hospital, New York, N. Y.

Dr. Bowman also announced three grants of financial aid to the organization. The Carnegie Corporation has appropriated \$25,000 for a critical survey of all work done to date on the effects of alcohol upon the individual, a project sponsored by the Department of Psychiatry of the College of Medicine, New York University. It is under the supervision of Dr. Norman Jolliffe, Associate Professor of Medicine at New York University, who recently directed a survey of alcoholism and the alcoholic psychoses in Europe.

Through the Council, the American Philosophical Society is financing a study of the toxic factors in alcoholism, conducted at the New York Psychiatric

Institute under the direction of Dr. George A. Jervis. In addition, the Dazian Foundation for Medical Research has granted funds through the Council for research on the rôle of alcohol in liver cirrhosis, a project being initiated by the College of Medicine at New York University. Some 200 patients with liver cirrhosis will be subjected to clinical, chemical, and pathological study in an effort to reach a clearer understanding of the relation of alcohol to this disease.

With these three studies inaugurated, the Research Council on Problems of Alcohol has now decided to concentrate upon alcoholism until the end of 1941. Three major measures will be employed: (1) the evaluation and coördination of existing research; (2) the development of a research program along lines inadequately investigated or not yet explored, and (3) the dissemination of the results of such research.

PERSONALS

Central States

DR. FRED T. ANDREWS, formerly of Kalamazoo, Mich., has been selected as Health Officer for Bay County, effective October 9.

DR. CYRIL V. BLACK, of Pratt, Kans., has been appointed Health Officer of Pratt, Kans., filling the unexpired term of the late DR. CHARLES E. PHILLIPS.

JAMES A. DOLCE, M.D.,† former Assistant Director of the Allegan County Health Department and County Health Officer of Allegan County, Mich., has been appointed Acting Director of the Sanilac County, Mich., Health Department, during the absence of DR. L. D. GASTON.

DR. GEORGE J. FRAZIER, of Gregory, S. Dak., was presented with the 1939 achievement medal by the Indian Council Fire at a meeting in Chicago held September 22. Dr. Frazier has

been in the Indian Service for 25 years and at present serves among the Sioux of South Dakota.

CLIFTON HALL, M.D., M.P.H.,† is serving as Acting Director of the Mecosta-Osceola, Mich., Health Department during the absence of DR. M. C. IGLOE, who is at Johns Hopkins. Dr. Hall was formerly in charge of tuberculosis control activities in the Kansas State Board of Health.

EDWARD G. MCGAVRAN, M.D.,† of Hillsdale, Mich., has resigned as Director of the Hillsdale County Department of Health, to devote his time to research.

ROBERT V. SCHULTZ, M.D.,† Fellow in Public Health Education with the W. K. Kellogg Foundation, Battle Creek, Mich., has been awarded The New York Academy of Medicine Fellowship granted by the Rockefeller Foundation for the study and critical evaluation of medical education methods over the radio.

DR. EDWIN O. SQUIRE has been appointed Health Officer for the Coffeyville, Kans., Board of Health.

HENRY F. VAUGHAN, D.P.H.,* Commissioner of Health of Detroit, Mich., has been elected President of the Michigan Public Health Association.

Eastern States

DR. HOWARD S. ALLEN has been appointed Health Officer of Woodbury, Conn., succeeding DR. FRANK REICHENBACH.

DR. HOMER C. ASHLEY, of New Hartford, Conn., has been appointed Health Officer of Barkhamsted, Conn., filling the vacancy caused by the resignation of MARSHALL CASE.

DR. WILLIAM T. DAVIS, of Scranton, Pa., has been appointed Medical Director of Lackawanna County, succeeding DR. JOHN J. BENDICK, of Olyphant.

* Fellow A.P.H.A.

† Member A.P.H.A.

DR. EZRA POPE DICKINSON, of St. Michael, Pa., has been appointed Medical Director of Cambria County, succeeding DR. JAMES J. O'CONNOR, of Barnesboro.

DR. NORMAN H. GARDNER has been appointed Health Officer of East Hampton, Conn., succeeding DR. JOHN D. MILBURN, resigned.

DR. WILLIAM L. HIGGINS, of South Coventry, has been appointed Health Officer of Columbia, Conn.

ALFRED KORACH, M.D.,† of Cambridge, Mass., where he has been associated with the Department of Biology and Public Health of the Massachusetts Institute of Technology as a visiting lecturer in public health administration, has now joined the Department of Preventive Medicine of the University of Cincinnati College of Medicine, as a lecturer on preventive medicine.

DR. DANIEL E. SHEA, formerly Director of the Bureau of Venereal Diseases of the Hartford, Conn., Department of Health on a part-time basis, has been appointed full-time Director of the Bureau.

Southern States

THOMAS H. BLAKE, M.D.,† Director of County Health Work of the West Virginia State Health Department, has resigned to enter private practice at St. Albans.

ROBERT E. BONDY, Director of Disaster Relief of the American Red Cross, has been appointed Director of Public Welfare of the District of Columbia.

JOHN F. CADDEN, M.D.,† of South Charleston, W. Va., Director of the Bureau of Industrial Hygiene of the West Virginia State Department of Health, has resigned, to become Medical Director of the plant of the American Viscose Corporation at Roanoke, Va.

DR. JOE DORROUGH, of Haileyville,

Okla., has been appointed Health Superintendent of Pittsburg County. DR. WELDON K. HAYNIE, of Durant, Okla., has been appointed Health Superintendent of Bryan County.

JOHN F. KENDRICK, M.D.,† of Raleigh, N. C., has been assigned temporarily by the International Health Division of the Rockefeller Foundation to direct the Stanley County project in health education in public schools that has been chosen by the State Board of Health and the State Board of Education as the first of a program to be financed by a \$50,000 grant from the Foundation.

DR. JOHN A. MORROW, of Sallisaw, Okla., has been appointed Deputy Health Commissioner of the Oklahoma State Health Department.

DR. BRUCE H. POLLOCK, M.D.,* of Point Pleasant, W. Va., has been appointed Director of County Health Work of the West Virginia State Health Department, succeeding THOMAS H. BLAKE, M.D.,† resigned.

DR. CHARLES N. SCOTT, Director of the Bureau of Venereal Disease of the West Virginia State Health Department, has accepted a position as Medical Director of the plant of the American Viscose Corporation at Nitro, W. Va.

Western States

ALVIN R. CLAUSER, M.D.,† of Los Lunas, N. M., has been appointed Deputy District Health Officer for New Mexico Health District No. 8, in the absence of DR. W. DRUMMOND RADCLIFFE who is attending Johns Hopkins University for a year in public health administration.

LYMAN C. DURYEA, M.D., C.P.H., who recently returned from Honolulu, has been appointed Director of the New York City Commission for the Study

* Fellow A.P.H.A.

† Member A.P.H.A.

of Crippled Children, succeeding Vernon W. Lippard, M.D.

FLORENCE FISHER has been appointed Acting Director of Public Health Nursing in the Department of Public Health during the absence of Mrs. FANNIE T. WARNCKE,† who is taking a course in public health nursing at Columbia University.

HELEN JAMES McMILLAN† has resigned as Consultant Nurse in the Division of Public Health Nursing of the New Mexico Department of Public Health, effective October 1.

DR. EDWIN E. MCNIEL, of Honolulu, has been appointed Director of the Bureau of Mental Hygiene and in charge of the Mental Hygiene Clinic under the Board of Health in Hawaii.

ROLLO J. SHALE, M.D., M.S.P.H.,† formerly Health Officer of Weld County, Colo., has been appointed Health Officer of Ontonagon and Baraga Counties, Mich. He succeeds PEARL A. TOIVONEN, M.D.,† who recently married Dr. Niilo E. Leppo, a Rockefeller Foundation fellow from Finland in this country.

DEATHS

DR. LIVINGSTON FARRAND,* president emeritus of Cornell University, died November 8, at the age of 72.‡ He became a member of the American Public Health Association in 1910

and a Fellow in 1922. He was Treasurer of the Association in 1913, on the Governing Council 1915–1918, 1926–1929, and 1930–1933. He served as Editor of the *American Journal of Public Health* in 1912 and 1913, and as one of the Advisory Editors from 1914 to 1916.

DR. ALLEN J. HRUBY,† Secretary and Trustee of the Chicago Municipal Tuberculosis Sanitarium, died November 18, at the age of 49.

DR. RICARDO JORGE, delegate from Portugal on the Comité Permanent de l'Office International d'Hygiène Publique, died recently. He wrote on many subjects, but notably on plague, yellow fever, cholera, typhus, smallpox, and la grippe. He is perhaps best known in this country through his coining of the word "peste selvatique," which Dr. Karl Meyer has put into use as "sylvatic" plague. Dr. Jorge first brought it to us in the publication "Rongeurs et puces dans la conservation et la transmission de la peste" (Rodents and Fleas in the Conservation and Transmission of Bubonic Plague). Dr. Jorge was 81 years of age.

CHARLES R. TYLER,† Bacteriologist in charge of the Diagnosis Laboratory of the New York City Department of Health, died recently, at the age of 59.

* Fellow A.P.H.A.

† Member A.P.H.A.

SECTION COUNCILS

HEALTH OFFICERS SECTION

(Organized 1908)

- J. N. Baker, M.D., *Chairman*, State Health Officer, Montgomery, Ala.
 Adolph Weinzirl, M.D., *Vice-Chairman*, Health Officer, Portland, Ore.
 Joseph W. Mountin, M.D., *Secretary*, U. S. Public Health Service, Washington, D. C.
 Gregoire F. Amyot, M.D. (1943)
 Edward S. Godfrey, Jr., M.D. (1942)
 John P. Kochler, M.D. (1941)
 A. H. Flickwir, M.D. (1940)
 Frederick D. Stricker, M.D. (1939)

LABORATORY SECTION

(Organized 1899)

- Thomas F. Sellers, M.D., *Chairman*, State Department of Health, Atlanta, Ga.
 Harold W. Lyall, Ph.D., *Vice-Chairman*, State Department of Health, Albany, N. Y.
 George D. Cummings, Ph.D., *Secretary*, State Department of Health, Lansing, Mich.
 Friend Lee Mickle, Sc.D. (1943)
 William D. Stovall, M.D. (1942)
 Ruth Gilbert, M.D. (1941)
 James Gibbard (1940)
 Robert S. Breed, Ph.D. (1939)

VITAL STATISTICS SECTION

(Organized 1908)

- A. W. Hedrich, Sc.D., *Chairman*, 2411 N. Charles Street, Baltimore, Md.
 John Collinson, M.D., *Secretary*, Bureau of the Census, Washington, D. C.
 Jessamine S. Whitney (1943)
 J. V. DePorte, Ph.D. (1942)
 George H. Van Buren (1941)
 Selwyn D. Collins, Ph.D. (1940)
 W. Thurber Fales, Sc.D. (1939)
 W. A. Davis, President, Association of State Registration Executives (*ex officio*)

PUBLIC HEALTH ENGINEERING SECTION

(Organized 1911)

- Roy J. Morton, *Chairman*, Vanderbilt University, Nashville, Tenn.
 Earnest Boyce, C.E., *Vice-Chairman*, State Board of Health, Lawrence, Kans.
 James Lloyd Barron, C.E., *Secretary*, 121 Fulton Street, Hempstead, N. Y.
 Joel I. Connolly (1943)
 Gerald M. Fair (1942)
 Arthur P. Miller, C.E. (1941)
 Warren J. Scott (1940)
 C. A. H. (1939)

INDUSTRIAL HYGIENE

(Organized 1914)

- J. J. Bloomfield, *Chairman*, U. S. Public Health Service, Washington, D. C.
 Clarence D. Selby, M.D., *Vice-Chairman*, General Motors Corporation, Detroit, Mich.
 W. J. McConnell, M.D., *Secretary*, 1 Madison Avenue, New York, N. Y.
 Leonard Greenburg, M.D. (1943)
 Leverett D. Bristol, M.D. (1942)
 Albert S. Gray, M.D. (1941)
 Henry H. Kessler, M.D., Ph.D. (1940)
 R. R. Sayers, M.D. (1939)

FOOD AND NUTRITION SECTION

(Organized 1917)

- D. Breese Jones, Ph.D., *Chairman*, U. S. Department of Agriculture, Washington, D. C.
 F. W. Fabian, Ph.D., *Vice-Chairman*, Michigan State College, East Lansing, Mich.
 Carl R. Fellers, Ph.D., *Secretary*, Massachusetts State College, Amherst, Mass.
 Milton E. Parker (1943)
 Marietta Eichelberger, Ph.D. (1942)
 Fred W. Tanner, Ph.D. (1941)
 Albert C. Hunter, Ph.D. (1940)
 Walter H. Eddy, Ph.D. (1939)

CHILD HYGIENE SECTION

(Organized 1921)

- Guy S. Millberry, D.D.S., *Chairman*, University of California, San Francisco, Calif.
 Martha M. Eliot, M.D., *Vice-Chairman*, U. S. Children's Bureau, Washington, D. C.
 Estella F. Warner, M.D., *Secretary*, Box 527, Albuquerque, N. Mex.
 Mayhew Derryberry, Ph.D. (1943)
 M. Luise Diez, M.D. (1942)
 Helen A. Cary, M.D. (1941)
 Don W. Gudakunst, M.D. (1940)
 J. H. Mason Knox, M.D. (1939)

PUBLIC HEALTH EDUCATION SECTION

(Organized 1922)

- Clair E. Turner, Dr.P.H., *Chairman*, Massachusetts Institute of Technology, Cambridge, Mass.
 Thomas G. Hull, Ph.D., *Vice-Chairman*, 535 N. Dearborn Street, Chicago, Ill.
 Carl A. Wiltzbach, M.D., *Secretary*, Commissioner of Health, Cincinnati, O.
 Mary P. Connolly (1943)
 Homer N. Calver (1942)
 W. W. Bauer, M.D. (1941)
 Marjorie Delavan (1940)
 Evert G. Routzahn (1939)

PUBLIC HEALTH NURSING SECTION

(Organized 1923)

Marguerite A. Wales, R.N., *Chairman*, W. K. Kellogg Foundation, Battle Creek, Mich.
Marion W. Sheahan, R.N., *Vice-Chairman*, State Department of Health, Albany, N. Y.
Ruth Houlton, R.N., *Secretary*, 50 West 50th Street, New York, N. Y.
Bettie W. McDanald (1943)
Alma Haupt, R.N. (1942)
Laura A. Draper, R.N. (1941)
Pearl McIver, R.N. (1940)
Olive M. Whitlock, R.N. (1939)

EPIDEMIOLOGY SECTION

(Organized 1929)

Milton J. Rosenau, M.D., *Chairman*, University of North Carolina, Chapel Hill, N. C.
G. Foard McGinnes, M.D., *Vice-Chairman*, State Department of Health, Richmond, Va.
Filip C. Forsbeck, M.D., *Secretary*, State Department of Health, Lansing, Mich.
Carl F. Jordan, M.D. (1943)
Haven Emerson, M.D. (1942)
Gaylord W. Anderson, M.D. (1941)
Alton S. Pope, M.D. (1940)
James P. Leake, M.D. (1939)

AMERICAN PUBLIC HEALTH ASSOCIATION

COMMITTEES

1938-1939

Committee on Eligibility

- Arthur P. Miller, C.E., *Chairman*, U. S. Public Health Service, Sub-Treasury Building, New York, N. Y. (1939)
Reginald M. Atwater, M.D., *Secretary*, 50 West 50th Street, New York, N. Y.
Mary V. Dempsey, Vital Statistics Section (1939)
Arthur E. Gorman, Public Health Engineering Section (1940)
Emery R. Hayhurst, M.D., Industrial Hygiene Section (1939)
Ira V. Hiscock, Public Health Education Section (1940)
Edmund K. Kline, Dr.P.H., Laboratory Section (1940)
Millard Knowlton, M.D., Epidemiology Section (1940)
George D. Lummis, M.D., Health Officers Section (1939)
Agnes J. Martin, R.N., Public Health Nursing Section (1939)
William B. Palmer, Food and Nutrition Section (1940)
Charles F. Wilinsky, M.D., Child Hygiene Section (1939)

Committee on Administrative Practice

- E. L. Bishop, M.D., *Chairman*, Tennessee Valley Authority, Chattanooga, Tenn. (1941)
Haven Emerson, M.D., *Vice-Chairman* (1941)
Reginald M. Atwater, M.D., *Secretary*, 50 West 50th Street, New York, N. Y.
Leverett D. Bristol, M.D. (1939)
Michael M. Davis, Ph.D. (1942)
Grant Fleming, M.D. (1940)
Joseph W. Mountin, M.D. (1942)
George T. Palmer, Dr.P.H. (1939)
W. S. Rankin, M.D. (1940)
Marion Sheahan, R.N. (1939)
L. R. Thompson, M.D., *Chairman*, Committee on Research and Standards (*Ex Officio*)
Henry F. Vaughan, Dr.P.H. (1940)
W. F. Walker, Dr.P.H. (1942)
H. A. Whittaker (1941)

Representatives from Health Officers Section

- Robert H. Riley, M.D.
John J. Sippy, M.D.
C. E. Waller, M.D.

Consultants

- Charles V. Chapin, M.D.
C.-E. A. Winslow, Dr.P.H.

L. R. Thompson, M.D., *Chairman*
Haven Emerson, M.D.
I. S. Falk, Ph.D.
H. S. Mustard, M.D.
John F. Norton, Ph.D.

Sub-Committee on Accuracy of Certified Causes of Death

Haven Emerson, M.D., *Chairman*
Fred L. Adair, M.D.
George Bachr, M.D.
E. H. Lewinski Corwin, Ph.D.
Thomas J. Duffield
Halbert L. Dunn, M.D., Ph.D.
John O. Spain
George H. Van Buren
Jessamine S. Whitney
Advisory Member
W. R. Williams, M.D.

Sub-Committee to Study Efficacy of Typhoid Vaccines

Joseph F. Siler, M.D., *Chairman*
R. E. Dyer, M.D.
William H. Gaub, C.P.H.
Ruth Gilbert, M.D.
Captain O. J. Mink
T. F. Sellers, M.D.

Sub-Committee on Public Health Problems

I. S. Falk, Ph.D., *Chairman*
Haven Emerson, M.D.
Harry S. Mustard, M.D.
L. R. Thompson, M.D.

Sub-Committee on Air Standards

Prof. Earle B. Phelps, *Chairman*
Leonard Greenburg, M.D.
Emery R. Hayhurst, M.D.
C. P. Yaglou

Sub-Committee on Communicable Disease Control

Haven Emerson, M.D., *Chairman*

Sub-Committee on Standard Methods for the Examination of Dishwashing Devices

A. Parker Hitchens, M.D., *Chairman*
Lt. Col. Wesley C. Cox, M.C., U.S.A.
James G. Cumming, M.D., Dr.P.H.
James P. Leake, M.D.
Lt. Col. Charles G. Souder, M.C., U.S.A.
Commander C. S. Stephenson, M.C., U.S.N.
Raymond V. Stone, D.V.M.

Sub-Committee on Soil Pollution

H. E. Miller, *Chairman*
Charles F. Craig, M.D.
F. Clarke Dugan, C.E.
V. M. Ehlers, C.E.
Leo F. Ey
James G. McAlpine, Ph.D.

Sub-Committee on Hygiene of Housing

C.-E. A. Winslow, Dr.P.H., *Chairman*
R. H. Britten, *Secretary*
Frederick J. Adams
F. S. Chapin, Ph.D.
Joel I. Connolly
Robert L. Davison
Earle S. Draper
James Ford, Ph.D.
J. Andre Fouilhoux
Greta Gray, Ph.D.
James E. Ives, Ph.D.
M. G. Lloyd, Ph.D.
George C. Ruhland, M.D.
Harold A. Whittaker
Clarence S. Stein
Richard Voell
Allan A. Twichell, *Technical Secretary*
Philip E. Nelbach, *Field Secretary*

Sub-Committee on Autopsies

Haven Emerson, M.D., *Chairman*
Lt. Col. George C. Dunham
W. Thurber Fales, Sc.D.
Harrison S. Martland, M.D.
Paul D. Rosahn, M.D.
Milton C. Winternitz, M.D.

Committee on Professional Education

W. S. Leathers, M.D., *Chairman*, School of Medicine, Vanderbilt University, Nashville, Tenn. (1942)

Reginald M. Atwater, M.D., *Secretary*, 50 West 50th Street, New York, N. Y.

E. L. Bishop, M.D. (1940)

Allen W. Freeman, M.D. (1939)

John E. Gordon, M.D., Ph.D. (1943)

Pearl McIver, R.N. (1941)

George H. Ramsey, M.D. (1943)

Wilson G. Smillie, M.D. (1941)

John Sundwall, M.D. (1940)

Ralph E. Tarbett, C.E. (1939)

Henry F. Vaughan, Dr.P.H. (1942)

William P. Shepard, M.D., *Consultant*

Lsabel B. Landy, *Associate Secretary*, 50 West 50th Street, New York, N. Y.

Editorial Committee

Henry F. Vaughan, Dr.P.H., *Chairman*

Allen W. Freeman, M.D.

George H. Ramsey, M.D.

Sub-Committee on the Educational Qualifications of Sanitarians, Public Health Engineers and Sub-Professional Field Personnel

Ralph E. Tarbett, C.E., *Chairman*

J. L. Barron, C.E.

Earnest Boyce, C.E.

Prof. Charles G. Hyde

Arthur P. Miller, C.E.

Sub-Committee on the Educational Qualifications of Health Officers

Allen W. Freeman, M.D., *Chairman*

John E. Gordon, M.D., Ph.D.

Prof. Ira V. Hiscock

George H. Ramsey, M.D.

Wilson G. Smillie, M.D.

Henry F. Vaughan, Dr.P.H.

Henry E. Meleney, M.D.

Sub-Committee on the Educational Qualifications of Health Educators

Sub-Committee A—Education and Qualifications of School Health Educators:

John Sundwall, M.D., *Chairman*

Edna A. Gerken

Anita Laton

Harold H. Mitchell, M.D.

James E. Rogers

Clair E. Turner, Dr.P.H.

Consulting Group Sub-Committee A:

Edna W. Bailey, Ph.D.

O. E. DeWese, M.D.

Ruth Groat

A. G. Ireland

H. E. Kleinschmidt, M.D.

Fredrika Moore, M.D.

Anette Phelan Watson, Ph.D.

Mabel E. Rugan, Ph.D.

W. Carson Ryan

Mary E. Spencer, Ph.D.

Lida Lee Tall

A. W. Thompson

Anne Whitney

Pauline Williamson

Charles Wilson, M.D.

Sub-Committee B—Education and Qualifications of Adult Health Educators:

John Sundwall, M.D., *Chairman*

W. W. Bauer, M.D.

Mary P. Connolly

Prof. Ira V. Hiscock

Evart G. Routzahn

Consulting Group Sub-Committee B:

Donald B. Armstrong, M.D.

Bertrand Brown

Walter H. Brown, M.D.

Herman N. Bundesen, M.D.

Marjorie Delavan

Haven Emerson, M.D.

Iago Galdston, M.D.

Howard W. Green

Don W. Gudakunst, M.D.

Gladys Kleinschmidt

H. E. Kleinschmidt, M.D.

W. W. Peter, M.D.

J. T. Phair, M.B.

Thurman B. Rice, M.D.

James A. Tobey, Dr.P.H.

Sub-Committee on the Educational Qualifications of Public Health Nurses

Pearl McIver, R.N., *Chairman*

Ellen L. Buell, R.N.

Ruth Hubbard

Virginia Jones, R.N.

George H. Ramsey, M.D.

Wilson G. Smillie, M.D.

Katherine Tucker, R.N.

Sub-Committee on the Educational Qualifications of Public Health Statisticians

John Sundwall, M.D., *Chairman*

Halbert L. Dunn, M.D., Ph.D.

Gaius E. Harmon, M.D.

A. W. Hedrich

George St. John Perrott

John E. Gordon, M.D., Ph.D.

Lucy Heathman, M.D.

C. A. Perry, Sc.D.

H. J. Shaughnessy

Sub-Committee on Field Experience Centers

W. G. Smillie, M.D., *Chairman*

George B. Darling, Dr.P.H.

Pearl McIver, R.N.

Roy J. Morton

Robert H. Riley, M.D.

Consultants:

Edward S. Godfrey, Jr., M.D.

John E. Gordon, M.D., Ph.D.

Sub-Committee on Education of Undergraduates in Preventive Medicine

Wilson G. Smillie, M.D., *Chairman*

John E. Gordon, M.D., Ph.D.

Alan Gregg, M.D.

W. S. Leathers, M.D.

Henry E. Meleney, M.D.

Kenneth F. Maxcy, M.D.

Sub-Committee on Educational Qualifications of Laboratory Personnel

W. D. Stovall, M.D., *Chairman*

Julia M. Coffey

Sub-Committee on Uniformity of Public Health Degrees

Reginald M. Atwater, M.D., *Chairman*

George H. Ramsey, M.D.

Association Committees

Association Nominating Committee

J. J. Sippy, M.D., *Chairman*, San Joaquin

Local Health District, Stockton, Calif.

Fred L. Adair, M.D., Child Hygiene Section

Mary D. Forbes, R.N., Public Health Nursing Section

Burt R. Rickards, Public Health Education Section

C. A. Holmquist, Public Health Engineering Section

Millard Knowlton, M.D., Epidemiology Section

Henry M. Loomis, Food and Nutrition Section

R. R. Sayers, M.D., Industrial Hygiene Section

George H. Van Buren, Vital Statistics Section

W. Carter Williams, M.D., Health Officers Section

Section Committees

Laboratory Section

Coördinating Committee on Standard Methods (allocated to Committee on Research and Standards)

A. Parker Hitchens, M.D., *Chairman*, Medical School, University of Pennsylvania, Philadelphia, Pa.

Robert S. Breed, Ph.D.

James Gibbard

R. A. Kelsner, Ph.D., D.V.M.

Friend Lee Mickle, Sc.D.

John F. Norton, Ph.D.

Elliott S. Robinson, M.D., Ph.D.

W. D. Stovall, M.D.

G. D. Cummings, Ph.D. (*ex officio*), *Secretary*, State Department of Health, Lansing, Mich.

Standard Methods Committee on Diagnostic Procedures and Reagents

W. D. Stovall, M.D., *Chairman*, State Laboratory of Hygiene, Madison, Wis.

Referee¹ for:

Diphtheria Virulence Tests—Donald T. Fraser, M.B., University of Toronto, Department of Hygiene, Toronto, Ont.

Gonorrhea and the Gonococcus—Charles M. Carpenter, M.D., University of Rochester, Rochester, N. Y.

Laboratory Diagnosis of Rabies—Thomas F. Sellers, M.D., State Board of Health, Atlanta, Ga.

Laboratory Diagnostic Procedures in the Recognition of Various Food Poisonings—S. A. Koser, Ph.D., University of Chicago, Chicago, Ill.

Laboratory Methods for the Diagnosis of Fungus Diseases—W. D. Stovall, M.D., State Laboratory of Hygiene, Madison, Wis.

Meningitis and Meningococcus—Sara E. Branham, M.D., Ph.D., National Institute of Health, Washington, D. C.

Recognition and Significance of Hemolytic Streptococci in Infectious Diseases—Julia M. Coffey, State Department of Health, Albany, N. Y.

Recognition of Pneumococcus Types Associated with Pneumonia—Elliott S. Robinson, M.D., Ph.D., Department of Public Health, Boston, Mass.

Serological and Bacteriological Procedures in the Diagnosis of Enteric Fevers—Marion B. Coleman, State Department of Health, Albany, N. Y.

Serological, Bacteriological and Other

Biological Procedures in the Diagnosis of Undulant Fever—G. D. Cummings, Ph.D., State Department of Health, Lansing, Mich.

Serological Tests for the Diagnosis of Syphilis—Ruth Gilbert, M.D., State Department of Health, Albany, N. Y.

Studies on the Toxicity of Dyes for Bacteria—Edmund K. Kline, Dr.P.H., Cattaraugus County Department of Health, Olean, N. Y.

Tuberculosis and the Tubercle Bacillus—A. L. MacNabb, D.V.M., Department of Health, Toronto, Ont.

Tularemia and Bacterium Tularense—J. G. McAlpine, Ph.D., District State Laboratories, Montgomery, Ala.

Typhus Fever and Laboratory Methods for its Recognition—Henry Welch, Ph.D., U. S. Food and Drug Administration, Washington, D. C.

Whooping Cough and B. Pertussis—Pearl L. Kendrick, Sc.D., State Department of Health, Grand Rapids, Mich.

Associate Referee² for:

Complement-Fixation Test for Syphilis—Elizabeth Maltaner, State Department of Health, Albany, N. Y.

Laboratory Diagnosis of Diphtheria—Martin Frobisher, Jr., D.Sc., Johns Hopkins University, Baltimore, Md.

Laboratory Diagnosis of Rabies—Harry Carnes, State Department of Health, Atlanta, Ga.

Laboratory Methods for the Diagnosis of Fungus Diseases—Lois Almon, Ph.D., State Laboratory of Hygiene, Madison, Wis.

Toxicity and Brilliant Green for Certain Bacteria—Cassandra Ritter, Water and Sewage Laboratory, University of Kansas, Lawrence, Kans.

Tuberculosis and the Tubercle Bacillus—M. H. Brown, M.D., University of Toronto, Toronto, Ont.

Tularemia and Bacterium Tularense—George D. Brigham, Ph.D., U. S. Quarantine Station, Mobile, Ala.

Whooping Cough and B. Pertussis—George McL. Lawson, M.D., Box 1113, Charlottesville, Va., and J. J. Miller, M.D., 2361 Broadway, San Francisco, Calif.

¹ Referees are members of the Standard Methods Committee upon which they serve.

² Associate Referees are not members of the Standard Methods Committee upon which they serve.

Standard Methods Committee on Examination of Water and Sewage

John F. Norton, Ph.D., *Chairman*, Upjohn Company, Kalamazoo, Mich.

Referee¹ for:

Bacteriological Methods for Water—Mac H. McCrady, 89 Notre Dame East, Montreal, Que.

Chemical Methods for Water—A. M. Buswell, Ph.D., Water Survey, 57 Chemical Building, Urbana, Ill., and S. T. Powell, State Department of Health, Baltimore, Md.

Chemical Methods of Sewage—F. Wellington Gilcreas, State Department of Health, Albany, N. Y.

Coliform Group Variants—Leland W. Parr, Ph.D., George Washington University, Washington, D. C.

Microscopic Methods of Water—Theodore A. Olson, State Department of Health, Minneapolis, Minn.

Swimming Pool and Bathing Place Waters—W. L. Mallmann, Ph.D., Michigan State College, East Lansing, Mich.

Waterways Pollution—M. S. Nichols, Ph.D., State Laboratory of Hygiene, Madison, Wis.

Standard Methods Committee on Examination of Dairy and Food Products

Robert S. Breed, Ph.D., *Chairman*, Box 299, Geneva, N. Y.

Referee¹ for:

Chemical Methods of Examining Dairy Products—F. C. Blanck, Ph.D., Bureau of Chemistry and Soils, Washington, D. C.

Comparative Tests of Agar Media for Standard Milk Work—C. A. Abele, Ch.E., State Board of Health, Montgomery, Ala.

Laboratory Equipment—R. V. Stone, D.V.M., 829 So. 6th Street, Alhambra, Calif.

Methods for Detecting Organisms of Colon Group—A. J. Slack, M.D., Institute of Public Health, London, Ont.

Methods of Counting Bacteria in Dairy Products—A. H. Robertson, Ph.D., State Department of Agriculture and Markets, Albany, N. Y.

Methods of Detecting Specific Types of Bacteria in Dairy Products—Mac H. McCrady, 89 Notre Dame East, Montreal, Que.

Associate Referee² for:

Bacteriological Methods of Examining

Ice Cream—F. W. Fabian, Ph.D., Michigan State College, East Lansing, Mich.

Laboratory Equipment—Clifford N. Stark, Ph.D., Cornell University, Ithaca, N. Y.

Methods of Examining Milk for Evidences of Brucella Infection—I. F. Huddleson, Ph.D., Michigan State College, East Lansing, Mich.

Methods of Examining Milk for Tubercle Bacilli—W. A. Hagan, D.V.M., 320 The Parkway, Ithaca, N. Y.

Methods of Identifying Streptococci in Dairy Products—G. J. Hucker, Ph.D., State Agricultural Experiment Station, Geneva, N. Y.

Methylene Blue Reductase Test—H. R. Thornton, Ph.D., University of Alberta, Edmonton, Alta.

Microbiological Methods for Examining Butter—E. H. Parfitt, Ph.D., Purdue University, Lafayette, Ind.

Milk Sediment Test—Caryl C. Carson, 166 Freeman Street, Hartford, Conn.

Standard Procedures for Controlling Milk at U. S. Army Posts, Captain A. T. Thompson, Army Medical Center, Washington, D. C.

Sterility of Dairy Utensils—Walter von D. Tiedeman, M.C.E., State Department of Health, Albany, N. Y.

Utilization of Milk and Digestive Milk on Standard Media—C. S. Mudge, Ph.D., University of California, Davis, Calif.

Standard Methods Committee on Biology of the Laboratory Animal

R. A. Kelser, Ph.D., D.V.M., *Chairman*, Office of the Surgeon General, U. S. Army, Washington, D. C.

Associate Referee²:

Paul A. Moody, Ph.D., University of Vermont, Burlington, Vt.

Captain Ralph Mohri, Army Medical Center, Washington, D. C.

George B. Wislocki, M.D., Harvard University Medical School, Boston, Mass.

Standard Methods Committee on Analyzing Frozen Desserts (Joint with the Committee of the Food and Nutrition Section)

Friend Lee Mickle, Sc.D., *Chairman*, Box 1139, Hartford, Conn.

Referee¹ for:

Chemical Analysis of Frozen Desserts and Ingredients—J. H. Shrader, Ph.D., 339 Springdale Avenue, East Orange, N. J.

Microbiological Examination of Frozen

Desserts—A. H. Robertson, Ph.D., State Department of Agriculture and Markets, Albany, N. Y.

Microbiological Examination of Ingredients—F. W. Fabian, Ph.D., Michigan State College, East Lansing, Mich.

Sediment Testing of Frozen Desserts and Ingredients—Milton E. Parker, 1526 S. State Street, Chicago, Ill.

Stabilizers and Gelatins in Frozen Desserts—James Gibbard, Department of Pensions and National Health, Ottawa, Ont.

*Associate Referee*² for:

Microbiological Examination of Condensed and Evaporated Milk—P. A. Downs, Ph.D., University of Nebraska, Lincoln, Neb.

Microbiological Examination of Dry Milk—Paul S. Prickett, Ph.D., Mead Johnson & Company, Evansville, Ind.

Microbiological Examination of Eggs—L. H. James, Ph.D., University of Maryland, College Park, Md.

Microbiological Examination of Flavors and Colors—M. J. Prucha, Ph.D., University of Illinois, Urbana, Ill.

Microbiological Examination of Fruits and Nuts—P. H. Tracy, Ph.D., University of Illinois, Urbana, Ill.

Microbiological Examination of Sugar—H. H. Hall, U. S. Department of Agriculture, Washington, D. C.

Sediment Testing of Butter and Eggs—Bernard E. Proctor, Ph.D., Massachusetts Institute of Technology, Cambridge, Mass.

Sediment Testing of Concentrated and Dried Milk—E. C. Thompson, The Borden Company, New York, N. Y.

Stabilizers and Gelatins in Frozen Desserts—

A. C. Dahlberg, Ph.D., Geneva, N. Y.
Thomas G. Downey, Ph.D., Camden, N. J.

A. C. Fay, Ph.D., Boston, Mass.

A. G. Lockhead, Ph.D., Ottawa, Ont.

P. F. Lucas, East Lansing, Mich.

M. P. Horwood, Ph.D., Massachusetts Institute of Technology, Cambridge, Mass.

Standard Methods Committee for the Examination of Shellfish

James Gibbard, *Chairman*, Department of Pensions and National Health, Ottawa, Ont.

C. A. Abele, Ch.E.

M. H. Bidwell

C. T. Butterfield

Hazel Hatfield, M.D.

A. C. Hunter, Ph.D.

C. A. Perry, Sc.D.

F. W. Tanner, Ph.D.

Standard Methods Committee on Biological Products

Elliott S. Robinson, M.D., Ph.D., *Chairman*, State Department of Health, Boston, Mass.

Robert D. Defries, M.D., D.P.H.

W. T. Harrison, M.D.

Ralph S. Muckenfuss, M.D.

Committee on Milk Pasteurization Studies
(allocated to Committee on Research and Standards)

G. J. Hucker, Ph.D., *Chairman*, Box 299, Geneva, N. Y.

Robert S. Breed, Ph.D.

L. H. Burgwald

Mac H. McCrady

R. P. Myers, Ph.D.

Robert C. Thomas

Laboratory Section Representative on the Commission for the Study of Biological Stains

W. D. Stovall, M.D., State Laboratory of Hygiene, Madison, Wis.

¹ Referees are members of the Standard Methods Committee upon which they serve.

² Associate Referees are not members of the Standard Methods Committee upon which they serve.

Health Officers Section

Committee on Coordination in Health Education (Joint with the Public Health Education Section) (Unallocated)

Clair E. Turner, Dr.P.H., *Chairman*, Massachusetts Institute of Technology, Cam-

bridge, Mass.

J. Rosslyn Earp, M.D.

Prof. Ira V. Hiscock

J. J. Sippy, M.D.

Henry F. Vaughan, Dr.P.H.

Harold H. Walker, C.P.H., Ph.D.

Vital Statistics Section

Committee on Accident Statistics (allocated to Committee on Administrative Practice)

Robert J. Vane, *Chairman*, 1 Madison Avenue, New York, N. Y.

Earle G. Brown, M.D.

J. V. DePorte, Ph.D.

Halbert L. Dunn, M.D., Ph.D.

W. Thurber Fales, Sc.D.

Irva C. Plummer

George H. Van Buren

R. L. Forney, *Consultant*

Committee on Forms and Methods of Statistical Practice (allocated to Committee on Administrative Practice)

A. W. Hedrich, Sc.D., *Chairman*, State Department of Health, Baltimore, Md.

Selwyn D. Collins, Ph.D.

John Collinson, M.D., Dr.P.H.

J. V. DePorte, Ph.D.

Halbert L. Dunn, M.D., Ph.D.

W. Thurber Fales, Sc.D.

Joseph B. Irvine, LL.M.

T. F. Murphy, M.D.

Elizabeth Parkhurst

Committee on Residence Allocation (allocated to Committee on Administrative Practice)

Elizabeth Parkhurst, *Chairman*, State Department of Health, Albany, N. Y.

A. W. Hedrich, Sc.D.

Leonard V. Phelps

Gerda C. Pierson

Francis D. Rhoads

Marie B. Stringer

Committee on Membership (Unallocated)

Willard C. Smith, *Chairman*, Social Security Board, Washington, D. C.

Lloyd R. Gates, Dr.P.H.

Marie B. Stringer

Thomas W. Chamberlain

Public Health Engineering Section

Committee on Bathing Places (Joint Committee with Conference of State Sanitary Engineers) (Allocated to Committee on Research and Standards)

W. J. Scott, *Chairman*, 34 Garfield Road, West Hartford, Conn.

Stephen De M. Gage

Chauncey A. Hyatt

Thomas M. Riddick

Advisers

Resolutions

THE following Resolutions* were unanimously adopted by the Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938:

I. APPRECIATION TO KANSAS CITY OFFICIALS AND GROUPS

RESOLVED that the officers and members of the American Public Health Association present at its 67th Annual Meeting in Kansas City, Missouri, express their sincere gratitude and deep appreciation to the City Manager, the Mayor, and the Council of Kansas City, and to the Chamber of Commerce for their reception and their gracious hospitality, and be it further

RESOLVED that the warm thanks of officers and members be extended to Dr. Edwin H. Schorer, Health Director of Kansas City, and General Chairman of the Local Committee, to every member of his committee, to the superintendents of the Municipal Hospitals and to the commissioners of the various divisions of the Health Department, for their many courtesies and their efficiency in making provisions for this meeting and in the conduct thereof.

II. APPRECIATION OF KANSAS CITY MUNICIPAL AUDITORIUM

RESOLVED that the American Public Health Association record its appreciation of the beauties and utilities of the Municipal Auditorium of Kansas City, and extend its thanks to the Director of the Auditorium and his staff for their effective support and aid in the planning and conducting of the numerous scientific sessions and social events held in the Auditorium.

III. THANKS TO THE PRESS AND RADIO

RESOLVED that the American Public Health Association acknowledge its indebtedness to the press and the radio, national, state and local, for its excellence of service in connection with the 67th Annual Meeting.

IV. APPRECIATION TO EXHIBITORS

RESOLVED that the American Public Health Association express its warm appreciation to its friends and co-operators who have presented at its 67th Annual Meeting such excellent exhibits, both scientific and technical, and which are of such great interest and value to the public health profession.

V. THANKS TO EXECUTIVE SECRETARY AND STAFF

RESOLVED that the commendation of the officers and of the members be recorded to the Executive Secretary, Dr. Reginald M. Atwater and his efficient staff.

VII. CONTROL OF TRICHINOSIS

WHEREAS thousands of necropsy examinations in many sections of the United States indicate that about 1 person in every 6 is infested with the trichina parasite, *Trichinella*

* Resolutions VI. Appreciation of Participation by Dr. Irvin Abell, VIII. Effective Control of Drugs, IX. Basic Requirements for Medical Practice and the Use of Animals in Scientific Research, and X. The National Health Program, were published in the December, 1938, issue of the *Journal*.

spiralis, and that approximately 2.5 per cent of positive cases represent infestations of a degree capable of producing clinical trichinosis,

WHEREAS these facts, together with a marked increase in the number of cases reported during the past few years, would seem to indicate that trichinosis is a public health problem of greater importance than has been realized previously, and

WHEREAS the methods now employed in the United States are not sufficiently effective nor sufficiently inclusive to form a basis for any adequate control of the disease, and

WHEREAS human trichinosis is based for the most part on swine trichinosis, and the most important factor in the causation of swine trichinosis is the practice of feeding uncooked garbage, containing scraps of raw pork, to swine, and

WHEREAS it would appear that 40 to 50 per cent of American municipalities dispose of their garbage by feeding it to swine, a practice which is directly responsible for the dissemination of the trichina parasite in the local population, and

WHEREAS the control of the practice of feeding garbage to swine appears at the present time to be the most practical, the most inexpensive and the most logical approach to the problem of trichinosis control, therefore be it,

RESOLVED that the American Public Health Association lend all encouragement possible to any plan looking to the control of human trichinosis, and urge that all public health officials be requested to give active support to any campaign for the control of this disease; that local and state health officials be requested to take due cognizance of local conditions as related to trichinosis and endeavor, when possible, to make provision for suitable control meas-

ures, such as the licensing of garbage feeding plants, the cooking of garbage for a period of time sufficient to destroy all trichinae, and the supervision of such plants by health departments or other suitable agencies; and That health officials of cities and towns should take active steps to encourage the use of methods of garbage disposal other than disposal by feeding to swine, or to encourage the cooking of municipal garbage before its consumption by swine, as a health measure for the protection of citizens of the municipality.

XI. IN MEMORIAM

RESOLVED that it is with a sense of irreparable loss that the American Public Health Association records the deaths since our last Annual Meeting of the following of its Fellows and members:

- Elmer G. Balsam, M.D., Billings, Mont.,
Elected Member 1935
- George P. Barth, M.D., Milwaukee, Wis.,
Elected Member 1918, Fellow 1928
- Professor Theodore J. Bradley, Boston,
Mass., Elected Member 1920
- Lawrason Brown, M.D., Saranac Lake,
N. Y., Elected Member 1915, Fellow
1923, Life Member 1929
- W. Alfred Buice, M.D., Dr.P.H., Chelsea,
Okla., Elected Member 1925, Fellow 1934
- William C. Buntin, M.D., Staten Island,
N. Y., Elected Member 1936
- Ada B. Coffey, R.N., New York, N. Y.,
Elected Member 1931
- Royal S. Copeland, M.D., New York, N. Y.,
Elected Member 1918, Fellow 1922, Life
Member 1936
- Samuel M. Creswell, M.D., Tacoma, Wash.,
Elected Member 1931, Fellow 1934
- R. B. Durfee, M.D., Bisbee, Ariz., Elected
Member 1919, Fellow 1934
- Paul Eaton, M.D., Orange Park, Fla.,
Elected Member 1930
- W. F. Elgin, M.D., Glenolden, Pa., Elected
Member 1900, Fellow 1922
- John N. Force, M.D., Dr.P.H., Berkeley,
Calif., Elected Member 1920, Fellow 1934
- Robert W. Fowler, M.D., Richmond Hill,
L. I., N. Y., Elected Member 1937
- Wade H. Frost, M.D., Baltimore, Md.,
Elected Member 1909, Fellow 1923

- Arthur M. Gibbs, M.D., C.P.H., Hamburg, Ark., Elected Member 1931
- Marion A. Gleason, M.D., Providence, R. I., Elected Member 1924
- Maurice C. Hall, Ph.D., D.V.M., Washington, D. C., Elected Member 1936
- I. Malinde Havey, R.N., Washington, D. C., Elected Member 1922, Fellow 1932
- Edgar R. Hiatt, M.D., Troy, O., Elected Member 1927
- Charles H. Hood, D.Sc., Boston, Mass., Elected Member 1913
- Vera H. Jones, M.D., Denver, Colo., Elected Member 1936
- Charles E. Kaufman, M.D., West Haven, Conn., Elected Member 1935
- Charles D. Kline, M.D., Nyack, N. Y., Elected Member 1919
- Charles H. Lawall, Sc.D., Philadelphia, Pa., Elected Member 1914, Fellow 1922
- Renwick H. Leitch, D.Sc., Auchincruive, Ayr, Scotland, Elected Member 1933
- Mary Lucier, New York, N. Y., Elected Member 1936
- Lloyd Moffitt, M.D., Yakima, Wash., Elected Member 1931, Fellow 1933
- August G. Nolte, Jefferson City, Mo., Elected Member 1937
- Arthur O. Peters, M.D., Dayton, O., Elected Member 1936
- O. C. Pickel, Ph.D., Salt Lake City, Utah, Elected Member 1926
- Henry S. Plummer, M.D., Rochester, Minn., Elected Member 1924
- Gus H. Radebaugh, Urbana, Ill., Elected Member 1933
- John M. J. Raunick, M.D., Harrisburg, Pa., Elected Member 1915, Fellow 1922
- T. H. Rockwell, M.D., New York, N. Y., Elected Member 1916
- William F. Roberts, M.D., St. John, N. B., Canada, Elected Member 1936
- George H. Roth, M.D., Los Angeles, Calif., Elected Member 1920, Fellow 1933
- Henry A. Rowland, Toronto, Ont., Canada, Elected Member 1920
- John N. Ryan, M.D., Passiac, N. J., Elected Member 1915
- DeWitt T. Smith, M.D., Dallas, Tex., Elected Member 1926
- Bertha K. Spector, Ph.D., Chicago, Ill., Elected Member 1919
- Belle M. Wagner, Chattanooga, Tenn., Elected Member 1926
- Jason Waterman, Washington, D. C., Elected Member 1935
- Frank L. Watkins, M.D., Great Falls, Mont., Elected Member 1927, Fellow 1931
- L. J. Zoeller, Ivorydale, O., Elected Member 1930, Fellow 1934

Reports of Committees

THE By-laws of the American Public Health Association provide that no standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council. Except where specifically noted to the contrary, the following reports are in the nature of progress reports from committees, most of which have had Section approval, but which have not been presented for Governing Council action, and therefore are not to be interpreted as standards approved by the American Public Health Association.

Hygiene of Housing*

1. *The Problem*

It is increasingly clear that the housing movement constitutes one of America's major interests at the present moment. Fifty-one housing projects have been completed in 36 cities under the Public Works Administration program, and the U. S. Housing Authority has at its disposal a sum of \$800,000,000 for further urban developments. The growth of interest in public housing is reflected in the fact that 220 cities now have municipal housing authorities, as compared with 45 cities one year ago. Furthermore, there is increasing recognition of the importance of other aspects of the problem, such as public housing for relief groups, housing for the rural population, development of housing plans on a self-supporting economic basis for higher income groups (assisted by loans from the Federal Housing Administration), and general rehabilitation of urban blighted areas. This type of activity appeals not only to governmental agencies; it has shown remarkable attractiveness to certain types of private enterprise, as illustrated

by the sponsorship of housing projects by certain insurance companies and philanthropic agencies. Throughout the entire housing field, health considerations, including those of mental and social as well as physical health, must be paramount.

2. *The Rôle of the Committee*

The Committee on the Hygiene of Housing was established in 1936 as a committee of the American Public Health Association, serving also as our national group coöperating with the Housing Commission of the Health Organization of the League of Nations. The active work of the committee has been made possible by grants from the Milbank Memorial Fund for the latter half of 1937 and for the year 1938. The committee, comprising 16 representatives of various technical fields concerned, and drawing its personnel from the entire country, has held 7 well attended meetings.

The committee has been represented (at League expense) at 3 meetings in Geneva, and will have a delegate at another meeting this winter; American experience has also contributed in important degree to reports issued from

* Report of the Sub-Committee, presented to the Committee on Research and Standards.

Geneva on heating and ventilation and lighting of the home. At the annual convention of the American Public Health Association in 1937, the committee presented a symposium, and in October, 1938, the chairman delivered an address on the rôle of the health officer in the housing program. (It is gratifying to note that, in the new edition of the *Appraisal Form for Local Health Work*, items relating to housing are for the first time included.) At both meetings, the committee was represented in the exhibit section. It also is planning and carrying out an exhibit on the hygiene of housing for the World's Fair in New York (at the expense of the sponsor of this particular exhibit). Our relations with the National Association of Housing Officials have been intimate and satisfactory, and its recent report on Physical Standards and Construction has been worked out in intimate relations with our staff and is essentially based on our recommendations.

We reported last year the completion of our first general committee report, on Basic Principles of Healthful Housing, which has been accepted as authoritative by the governmental agencies interested in this field and has had wide circulation among housing officials, health officers, technicians, colleges, and universities. During the past year, the committee staff has completed an extensive study of heating and ventilation, lighting and problems of noise, and conditions affecting accidents, in occupied dwellings in New Haven, New York, and Norris, Tenn.—the first study ever made in this country which reveals the actual conditions obtaining in the home. With this study have been combined important researches under the direction of E. S. Draper in experimental houses operated by the Tennessee Valley Authority. From this work there have emerged numerous points which will be of substantial aid in

planning housing projects. Professor Adams, of the Massachusetts Institute of Technology, has been engaged in a study for the committee on recreational space requirements, a field where it is most important that concrete evidence should replace armchair generalization. Professor Chapin, of Minnesota, is conducting investigations of the social results which ensue when families are moved from bad to good housing conditions. Mr. Whittaker, of the Minnesota State Department of Health, has prepared an admirable discussion, with detailed plans, of sanitary provisions for the isolated rural home; and Mr. Britten, of the U. S. Public Health Service, is making an analysis of housing data in the National Health Survey which should prove of substantial importance.

3. Looking Ahead

At the recent meeting of the committee in Washington, it was decided that, in the immediate future, our major efforts should be concentrated on the development of a program for the effective coöperation of health officers in the housing program. In certain cities we have been asked to assist health departments in preliminary surveys to be conducted by them in connection with the housing program of the cities operating under U.S.H.A. grants, and other cities have asked for our help in the development of adequate housing ordinances. Under the stimulus of the federal program, it seems certain that more widespread and fundamental housing surveys will be conducted during the next year than ever before, and it is very probable that at no time in the future will quite such extensive investigations of this kind be carried out. The most immediate need is for a suitable survey technic which can be used as a basis for obtaining federal funds, as an aid in the selection of sites for new projects, and as a guide for

demolition and rehabilitation in sub-standard areas. The committee is now at work on such a schedule in coöperation with the U.S.H.A. and the F.H.A. Our next problem is to study existing legislation in various cities and to devise means for coördinating the efforts of the health department, the building department, and the fire department in evolving a unified plan for local work. Our field studies and the investigations of heating and ventilation, lighting, noise control, home safety, recreation space, and social aspects of housing will be continued. It is our belief that these studies will ultimately make a substantial contribution to rural housing and to housing of upper-income classes on an economic basis, as well as in the field of federally subsidized urban housing.

The invitations which representatives of the committee have received to participate in programs of the American Public Health Association, the National Association of Housing Officials, the American Society of Planning Officials,

and the International Management Congress, as well as the coöperation which has been shown by the United State Housing Authority, the Federal Housing Administration, and the official group now studying the possibility of a housing census in 1940, offer gratifying evidence of the fundamental rôle which the committee may play in this field.

Association Committee on American Museum of Hygiene*

AT the time of our report last year we had not been advised of the founding of the first organization set up in America specifically for the purpose of organizing, financing, and equipping a museum of hygiene. This institution was incorporated on December 7, 1936, as the Cleveland Museum of Health and Hygiene. This group has prepared a statement of its objectives and is now engaged in developing the necessary basic support.

We are now able to record the founding of the second such organization. This, the American Museum of Health, Inc., was incorporated on December 11, 1937, its principal office being in New York City. The incorporators of the New York organization were members of the Advisory Committee on Medicine and Public Health of the New York World's Fair. This museum expects to obtain the nucleus for its exhibit collection from the medical and public health exhibits which are being developed for that Fair. Mayor LaGuardia has promised the group that it will have a building available for its museum at the conclusion of the Fair, and plans are now being developed in preparation for the formal opening at that time of a museum of hygiene in New York City.

In the meantime, the American Museum of Health has signed a contract with the Fair under which it assumes direct responsibility for a number of exhibits in the Fair. Moreover, all contracts with sponsors of exhibits

in the medical and public health building of the Fair provide that these exhibits shall become the property of the Museum at the end of the Fair.

Our committee, mindful of its basic responsibility to promote and encourage the development of museums of hygiene in the United States, has given considerable support to the New York Museum in the belief that nothing could better assure the development of museums of hygiene in America than the example that would be set by the establishment of one such outstanding museum. The committee's experience with reference to Chicago where adequate advance preparation might have made possible the immediate creation of a hygiene museum in that city at the end of the Century of Progress, has led it to recognize that the advent of the New York and San Francisco Fairs offered unusual opportunities for the establishment of such museums in one or both of these cities.

Members of our committee have therefore been active in connection with the medical and public health exhibits at both Fairs. Although it is reported that the museum committee of the Western Branch of the Association has been practically dissolved, the health education section of that branch continues its interest and is hopeful that at the end of the San Francisco Fair it may be able to assemble some of the public health exhibits there as a nucleus for a museum on the West Coast.

While there was no organization ready to utilize the Century of Progress Exposition to the fullest extent in

* Seventh Annual Report of the Committee presented to the Governing Council

creating a museum in Chicago, a number of exhibits from that exposition have for the present been housed in the Museum of Science and Industry, founded by Julius Rosenwald. With this nucleus, the medical wing of about 35,000 square feet is rapidly being filled. This is a first class exhibit operating under trained direction and, serving as a demonstration, it may lead to the creation of an independent museum of hygiene.

In the meantime a further demonstration of the popular interest of such exhibits has been furnished by the health exhibit at the New York Museum of Science and Industry, which was opened in November, 1937. This exhibit occupies approximately 10,000 square feet of floor space and since its opening the average monthly attendance at this museum has been approximately 40,000. The principal item in this health exhibit is the comprehensive collection of material purchased by the Oberlaender Trust from the German Hygiene Museum in Dresden, in the selection of which our committee aided. This material of the Oberlaender Trust is without doubt the outstanding collection of health exhibit material in America at the present time. It is expected that most of it will be on display at the New York World's Fair in the summer of 1939.

The committee notes with satisfaction the rapidly growing interest in health exhibits. Members of the committee and its staff have been invited to present the museum idea before various groups, and there is a small but growing number of inquiries received at the office of the committee.

Since our last report the committee has issued two publications. The first,

referred to in our last report as then in preparation, is the study of the health museum idea prepared for the committee by Dr. Benjamin C. Gruenberg. The second is the proceedings of the conference held under the auspices of the committee at the last meeting of the American Public Health Association. At that conference there were presented the original drawings and floor plans for an ideal health museum, which plans were based on a functional study of such an institution made by the New York architect, I. Woodner-Silverman. A scale model of this museum is on display among the scientific exhibits at this meeting in Kansas City. This model is a part of the general exhibit of the Museum Committee.

The committee has enjoyed this year a continuation of the grant from the Carnegie Corporation. This, together with funds and services which have been made available by the New York World's Fair, have enabled the committee to carry on a constantly growing program.

Looking to the future, we believe the time is not far off when this program of museums of health for America will be able to stand on its own feet, supported by a group of museums throughout the country. Pending that time, and to insure its arrival, we recommend a continuation of this committee.

School Health Policies*

Child Hygiene Section

THE Section recommended that the report be published in the *Year Book* of the Association and that the report be referred to the American School Health Association for further consideration, discussion, and confirmation. It was recommended that an effort be made to determine a consensus of current opinion upon the policies outlined in this report.

Because of limited space this report cannot be printed. The following is a brief abstract. It is hoped that the American School Health Association can arrange for publication.

SCHOOL HEALTH POLICIES

This statement of school health policies is planned—(1) To delineate the responsibilities of School Health programs—and (2) To relate the school health program to the health programs or health activities of other groups. In other words, it is an attempt to outline those things which schools should and should not do in the field of health.

The report emphasizes that "the school health service program may satisfactorily be administered by either a Board of Education or a Board of Health. . . . In either type of administration, specific important responsibilities will be delegated to teachers and from many points of view, the teacher must be considered a key person in school health activities.

The teacher will need the assistance of specialists in the health field . . . nurses, physicians, etc. . . . and these can assist the teacher regardless of the department of civic government to which they are responsible."

The report points out "that the school health program is only one of many activities directed toward the preservation and improvement of child health and that it should be closely coördinated with all other community health activities."

"For purposes of discussion and simplification, the committee considers all school responsibilities for pupil health under 8 headings:

1. To provide a *Healthful Environment*—This includes attention to the arrangement of the school program and the social and emotional tone of the classroom as well as attention to school sanitation.

2. To have a *Planned Program for the Care of Accidents* occurring at school and for cases of sudden sickness.

3. To have a *Planned Program for Assisting in the Community Program of Contagious Disease Control*.

4. To *Teach Pupils Habits and Attitudes* conducive to the maintenance of good health, and to *Facilitate the Accumulation of Scientific Knowledge* relating to the causes of disease, the way certain diseases are spread, and the known methods of preventing disease from the point of view of both individual and community health.

5. To *Encourage the Periodic Health Examinations* of pupils, to develop a plan whereby such examinations will be obtained, and to keep a cumulative record of the findings and recommendations.

6. To *Give Special Attention to Those in Need of Medical or Dental Care* through a follow-up program which will, where necessary, guide pupils and parents to sources of medical and dental treatment.

*Excerpt from a Report of the Committee on School Health Service, presented to the Section. The full report may be obtained in mimeographed form from the Chairman, Charles C. Wilson, M.D., 145 High Street, Hartford, Conn.

7. To *Provide Special Education Programs* adapted to the needs of handicapped pupils.

8. To *Provide Supervision and In-service Training for Teachers* and to place specific responsibility in the hands of some person especially qualified in education and in school health work for coördinating all school health activities and for relating these to community health programs.

"Policies change with time. What is considered good policy at the present time may not coincide with what was recommended several years ago, and the

future will unquestionably modify present views. The committee is aware of the transient nature of policies, but believes that progress and understanding are dependent on clear-cut statements of viewpoints. Through, specific statements of policy it hopes to contribute to the progress of school health programs."

HAROLD H. MITCHELL

Analyzing Frozen Desserts and Ingredients*

Food and Nutrition Section

THE first year of the Frozen Desserts Committee was occupied mainly with organizing the committee and determining what to do and the best way of doing it. Since the committee is a joint one working with a similar committee from the Laboratory Section of the Association, it was necessary to work out certain policies to produce a harmonious joint committee. This has been done to the entire satisfaction of all members on both committees so that the work is now progressing in a very satisfactory way.

BROAD FIELD IN FROZEN DESSERTS

It is fortunate that the Association had the vision to create a committee to study the subject of frozen desserts, since it is not only an increasingly important field but also a very broad one. The scope of the work as comprehended by your committee includes not only all the frozen desserts, but also all the ingredients which enter into their manufacture. Furthermore, we are attempting to formulate standard methods for the bacteriological, chemical, and physical examination of the finished product, as well as the ingredients used in making the finished product.

We are certain that those familiar with the field will agree that this is an ambitious program and will take considerable time and work to formulate

standard methods covering so many products. When one considers the years of time and the vast amount of work that have been expended in producing Standard Methods for Milk and Water Analysis, he begins to comprehend the task before us. It is for this reason that we beg your patient indulgence.

ORGANIZATION OF COMMITTEE

The Frozen Desserts Committee as now organized, has three members from the Laboratory Section—F. L. Mickle, A. H. Robertson, and James Gibbard; and three members from the Food and Nutrition Section—F. W. Fabian, J. H. Shrader, and M. E. Parker. Five of these members are referees for the following:

- I. A. H. Robertson, *Referee*, Bacterial Analysis—Finished Products
- II. F. W. Fabian, *Referee*, Bacterial Analysis of Ingredients
M. J. Prucha, *Associate Referee*, Bacterial Analysis of Flavors, Colors, Extracts, etc.
P. A. Downs, *Associate Referee*, Bacterial Analysis of Condensed and Evaporated Milk
P. S. Prickett, *Associate Referee*, Bacterial Analysis of Dry Milk
H. H. Hall, *Associate Referee*, Sugars and Sweetening Agents
P. H. Tracy, *Associate Referee*, Bacterial Analysis of Fruits and Nuts
L. H. James, *Associate Referee*, Eggs and Egg Products
- III. James Gibbard, *Referee*, Bacterial Analysis of Stabilizers

* Report of the Joint Standard Methods Committee of the Food and Nutrition and Laboratory Sections presented to the Food and Nutrition Section.

IV. J. H. Shrader, *Referee*, Chemical Analysis of Frozen Desserts and Their Ingredients

V. M. E. Parker, *Referee*, Sediment Testing for Frozen Desserts

E. C. Thompson, *Associate Referee*, Sediment Testing of Condensed and Dried Milks

George F. Stewart, *Associate Referee*, Sediment Testing of Egg Products

NOTE: Preliminary reports of all the referees and associate referees are now in the hands of the committee. These reports will be edited and made uniform.

PLAN OF PROCEDURE

At the last meeting of the committee, it was decided that when Standard Methods had been formulated by a referee or associate referee, they should be approved by the Joint Committee if found satisfactory and mimeographed copies sent to as many laboratories as possible for trial and criticism. At the end of this period they would be revised and published in the *Year Book* of the Association for further trial and criticism. After which they will be published as Standard Methods, either

tentative or official, presumably as a part of Standard Methods for the Examination of Dairy Products. This may seem a long and to some an unnecessary procedure but the committee feels that this is the only safe way to get satisfactory methods.

Many of the methods are already written and will soon be mimeographed and ready for distribution during the coming year. The committee asks your wholehearted coöperation in this matter. If you are doing this kind of work and do not receive copies of the methods during the coming year, please write for them. If you do receive copies of the methods, please try them out and write your suggestions and criticisms.

Status of Pasteurization of Milk and Milk Products*

Food and Nutrition Section

SEVERAL reports of this committee in recent years have in part dealt with the subject of pasteurizing milk and milk products. Within the past few years, however, considerable has been added to our knowledge concerning the effects of pasteurization on milk, the efficiency of pasteurizing equipment, and the satisfactory control of the pasteurization process. For these reasons the members of your committee have decided to confine their report to a discussion of the present status of pasteurization.

The pasteurization process is without doubt the most important single factor from the public health standpoint in the handling of milk and milk products. The necessity to insure the safety of our milk supplies through pasteurization is no longer questioned by the vast majority of doctors, public health workers, and sanitarians. In this respect opinion has changed rapidly in the past few years. The general acceptance of the practice is clearly portrayed by the fact that, in all cities with a population over 10,000, an average of at least 88 per cent of the milk supply is pasteurized.¹ That the safety of raw milk, however carefully safeguarded, must be questioned is tacitly implied in the action of the American Association of Medical Milk Commissions. At their annual meeting in June, 1935, that as-

sociation voted unanimously to approve the sale of "Certified Milk-Pasteurized." Certified Milk-Pasteurized has been sold in several of our cities since 1935.

Pasteurization has been upheld in the courts in several instances, hence the power of municipalities and states to enforce compulsory pasteurization has been on several occasions legally recognized.²

Objections to the pasteurization of milk, however, are still voiced. Pottinger,⁴⁵ writing in the magazine, *Certified Milk*, presents the commonly expressed criticisms of heat-treated milks and gives data from his case records in an attempt to show evidence of the value of raw milk over heat treated milk.

Many tabulations of milk-borne epidemics of various diseases appear in the literature which show that such outbreaks of disease are almost always confined to raw milk. When disease has been transmitted through milk said to be pasteurized, and a study of processing methods has been possible, it has invariably been found that the milk was not held at the proper temperature, or for a sufficient time, or was contaminated after pasteurization. Milk-borne disease epidemics are often spectacular with many cases developing within a few days and some often resulting in deaths. This may impress the public and emphasize the need for carefully pasteurizing all milk. How-

*Report of the Milk and Dairy Products Com-

ever, when considering the public health value of pasteurization, the reduction in infant morbidity and mortality in areas where the process is in vogue, which is usually marked, should also be included in the study. Admitting these facts, let us consider the effect of the pasteurization process on the food value of milk.

FOOD VALUE OF RAW VERSUS PASTEURIZED MILK

The comparative food value of raw and pasteurized milk has been a controversial subject in past years. Fortunately the results of a sufficient number of researches have been published on this subject in recent years so that a satisfactory conclusion can now be drawn. Studies with experimental animals, too numerous for enumeration in this report, have been conducted here and abroad. These experiments invariably indicate that there is no difference in food value between raw and pasteurized milk. It is of much greater significance that this conclusion is borne out by studies with children. The most significant studies of the growth of children on raw and pasteurized milk have been those of Leslie C. Frank,³ who tabulated weight and height data for 3,700 children, and Leighton and McKinley,⁴ who studied the growth of 20,000 school children in Lanarkshire, Scotland. These studies show that children on pasteurized milk thrive fully as well as those on raw milk.

Of more than passing interest are two studies with calves which were carried out in England.^{5,6} Cow's milk is the natural food of the calf. Hence, the effect of heating milk for calf feeding should be of especial significance. The outcome of both experiments was similar in that no difference was found in growth and performance between the groups of calves fed raw milk and those fed pasteurized milk.

EFFECT OF PASTEURIZATION ON CERTAIN DIETARY ESSENTIALS

A considerable amount of work has been reported regarding the effect of pasteurization on the vitamins of milk. It is generally agreed that the process does not lower the vitamin A, carotene, or vitamin D content of milk.^{7, 8, 10, 42} However, pasteurized milk may contain less vitamin B (B_1), C, and G than raw milk. Dutcher⁹ found that the maximum destruction of vitamins B and G during pasteurization to be about 38 per cent, but states further, "under carefully controlled plant operation need not be as great as indicated above." However, Krauss, *et al.*, report that 25 per cent of the vitamin B is destroyed during pasteurization but vitamin G is unharmed. Kon¹³ found a 20 per cent destruction of vitamin B during pasteurization.

Since the vitamin C content of raw milk is low, it is impossible to judge accurately through bio-assays the effect of the pasteurization process on this vitamin. For several years it was generally conceded, however, that the vitamin was almost entirely destroyed by pasteurization. With the recent introduction of the titration method for ascorbic acid in milk, a technic for measuring accurately the vitamin C content has become available, and studies are being made by this method to make comparatively accurate determinations.

In the absence of copper contamination from the equipment, the loss of vitamin C by the titration method has been found to be much lower than anticipated. Two investigators, Fellers⁷ and Kon,⁸ report a loss of at least 20 per cent of vitamin C due to oxidation of ascorbic acid during pasteurization. Sharp, however, has shown that the presence of copper and time of storage have much more effect on the extent of oxidation of ascorbic acid than heating the milk.¹¹ Sharp draws the following

conclusions from this work, "It is commercially feasible to pasteurize milk by the holder method and maintain essentially as high an ascorbic acid content as that of raw milk at the same age. This removes the main nutritional objection of pasteurized milk."

Unless light is excluded the vitamin C content of milk decreases during storage, the rate depending on the light intensity. The recent work of Kon and Watson¹² shows that milk may contain two forms of ascorbic acid—the reduced and the reversibly oxidized forms. Milk taken directly from the udder without exposure to light contains only the reduced form of ascorbic acid and can be pasteurized without loss of the vitamin, in the absence of copper; the reversibly oxidized form of ascorbic acid is formed by the action of light upon the milk and is affected by pasteurization.

Guthrie, Hand, and Sharp⁴⁶ have found that the vitamin C content can be retained completely in milk if the air is removed from the fresh milk by placing it under partial vacuum. Raw, pasteurized, and pasteurized milk containing copper were stored for periods of 7 days with no measurable loss of vitamin C when treated in this manner.

It is possible that the wide variations previously reported regarding the effect of processing of milk on the vitamin C content may have been caused by the length of exposure of the milk samples to light before the titrations for ascorbic acid were completed.

References regarding the effect of pasteurization on the digestibility of calcium in milk are controversial. Mattick and Hallett¹⁴ report a 2 per cent loss in calcium due to pasteurization. Daniels,¹⁵ Magee,¹⁶ and Kramer¹⁷ also believe there is a slight reduction. However, Courtney¹⁸ found no discernible difference, while Krauss,¹⁹ and Kon⁸ found that calcium and

phosphorus both were as readily available in pasteurized as in raw milk.

Though there is evidently some loss of vitamins B, C, and G due to pasteurization, the fact remains that, with both children and experimental animals, no differences in food value have been found between raw and pasteurized milk. This indicates that milk in the quantities usually ingested contains more than enough of these essentials or is supplemented sufficiently by the other foods which make up the diet of the average child.

PASTEURIZATION OF MILK PRODUCTS

Less information is available concerning the extent of pasteurization of sweet cream for table use than is the case with milk. However, it is reasonable to assume that the process is as widely used with market cream as with milk. In general, slightly higher temperatures are employed with cream than with milk. In pasteurizing milk by the holder method, temperatures of 142 to 145° F. with a 30 minute holding period are most frequently practised. As for cream, at least 145° F. is maintained, and frequently temperatures as high as 150° to 155° F. are used to enhance the keeping quality, since the cream is frequently older than milk when consumed.

Evaporated, condensed, and powdered milk products receive during processing temperature treatments in excess of those used in ordinary pasteurization. Hence, from the public health standpoint they must be considered to have received at least the equivalent of pasteurization. The milk used in these products is invariably heated to temperatures higher than 145° F., often near the boiling point before it is condensed. Canned evaporated and condensed milks are also heated to relatively high temperatures after canning to insure satisfactory keeping proper-

ties and, therefore, are made bacteriologically safe.

Reference to the report of this committee for 1937¹⁹ shows that a fairly large number of disease epidemics have been traced to both butter and cheese. A considerable quantity of "farm" butter made from raw cream is still being sold and much of the cheese being consumed has been made from raw milk. The committee¹⁹ advocated the requirement that all milk and cream used in the making of butter and cheese be properly pasteurized. Not only is this sound from the public health point of view but is good commercial practice. The keeping quality of butter is enhanced when cream used in its manufacture is pasteurized. Since the process largely inactivates the enzyme, lipase, oxidation of the butter fat is less likely to occur. Pasteurization of milk for cheese making has been advocated frequently within the industry because a more uniform quality can be maintained, less spoilage occurs, and a better yield is realized. This has been shown by the work of several investigators, as Price,²⁰ Phillips,²¹ Tuckey,²² and Reid.²³

The optimum temperature for the pasteurization of ice cream mix has been a controversial question. A previous report of this committee (1929) indicated that 143.5° F. for 30 minutes was adequate to insure pasteurization of the mix.²⁷ Since that time there has been an increasing number of bacteriologists and public health workers who advocate a temperature sufficiently high to destroy *E. coli*. The absence of *E. coli* in ice cream is considered by some as an index of effective pasteurization, and by others as an indication of sanitary methods during handling and dispensing. Fabian and Coulter,²⁸ Meyers and Sorenson,³⁰ and Yale³¹ have shown that pasteurizing at 155° F. for 30 minutes will destroy *E. coli*. It has also been shown that

the amount of sugar present has a protective action for bacteria.^{28, 29} There has been a tendency in recent years to increase the sugar content of ice cream. For these reasons the ice cream manufacturer has gradually increased the temperature of pasteurization so that, at present, 155° to 165° F. for 30 minutes is common practice. These temperatures are adequate to destroy any pathogenic bacteria which might be present in the ice cream mix.

CHANGES IN PASTEURIZATION EQUIPMENTS AND METHODS

There has been a steady improvement in the efficiency of pasteurization equipment. In much of the earlier equipment faulty design and construction left channels through which viable pathogenic bacteria could pass, and improper construction often resulted in unnecessary physical changes in the product. Though considerable progress has been made in the engineering of pasteurization equipment, as Holmquist and Tiedeman point out in a recent survey of the problem,²⁴ there is still need for further improvement. Metals used in pasteurization have been studied and new alloys developed which are more suitable for milk-contact surfaces.

There has been a gradual change in pasteurization methods since the commercial pasteurization of milk began. High-temperature-short-time methods were commonly practised at that time. However, such pasteurization equipment was condemned by public health officials because proper control of the process seemed impossible. The development in the past few years of sensitive control devices and efficient milk heaters has again revived interest in high-temperature-short-time methods. As a result of these recent developments, plate heater pasteurizers and electric pasteurizers have been tested by public health officials in a number of states and accepted by some. High-tempera-

ture-short-time pasteurization has been reviewed recently by several investigators, among them both Yale²⁵ and Putnam.²⁶

TESTS FOR EFFICIENCY OF PASTEURIZATION

Since the entire quantity of milk or milk product being pasteurized must be heated to the desired temperature and held for the required time, if the process is to reach its greatest usefulness, some satisfactory way of determining the efficiency of pasteurization is highly desirable. In the past no such test has been available. Hence milk sanitarians have found it necessary to determine the efficiency of the process by inspecting pasteurizing equipment, thermometers, and records of temperature and time-holding recording devices.

Some laboratory tests have been suggested for determining pasteurization efficiency. A modification of the Rothenfusser test has been advocated but was found to be lacking in sensitivity.³² The standard plate count and tests for coliform organisms have also been found to be unsatisfactory.³³ The measurement of the activity of the enzyme, amylase, has been found to furnish a fair index to the temperature treatment of the milk,³⁴ although the test is not sufficiently sensitive for control work.³⁵ However, the phosphatase test, developed by Kay and Graham,³⁶ has been found to be sufficiently sensitive to indicate minor changes in the temperature and time of pasteurization, as well as contamination with very small amounts of raw milk.^{33, 35} The tremendous interest shown in this test is evident by the space given to it on the program of this Association for 1938, at recent meetings of milk sanitarians and dairymen, and by numerous articles in our scientific journals and trade papers.

The phosphatase test has been modi-

fied by Gilcreas and Davis³⁵ of the New York State Department of Health, and by Scharer of the New York City Department of Health.^{41, 36} A more rapid test was needed than the original Kay and Graham method or the modification suggested by Gilcreas and Davis. For routine plant or laboratory work where a large number of samples must be examined a relatively simple and rapid method is essential. The rapid field test of Scharer,⁴¹ however, was not sufficiently sensitive to indicate small but significant differences in temperature and time of holding milk during the pasteurization process. Further developments in the method recently worked out by Scharer³⁶ presumably have increased considerably the sensitivity of the rapid phosphatase test which he has formulated. Different color standards for the phosphatase test than those used by Gilcreas and Davis³⁵ have been suggested by Spencer,³⁷ Boynton,³⁸ and by Scharer.³⁶

The phosphatase test is being used satisfactorily in determining the efficiency of the pasteurization of table cream. A modification of the test has been applied to butter by Brown and Parfitt,³⁹ who found when examining samples of commercial butter, about 31 per cent of the butters appeared not to be pasteurized. Kay and Neave⁴³ also have studied the modification of the phosphatase test for use with butter as well as cheese. Hahn and Tracy⁴⁰ found that the phosphatase test can be used successfully with certain limitations to determine the pasteurization of ice cream mix. However, a number of flavoring materials appear to carry free phenol, hence the test cannot be applied to finished ice cream. The work of Krueger⁴¹ substantiates that of Hahn and Tracy.

It should be borne in mind that the phosphatase test, however useful, is not an official method. In the near future this Association should appoint a

special committee to study the phosphatase test and suggested modifications, with the purpose of proposing a standard procedure for adoption by the American Public Health Association as an official test for the pasteurization of milk.

Your committee has attempted in this report to review the many developments within recent years which have added to our knowledge of the subject of the pasteurization of milk and dairy products. It is our hope that this resumé will serve the purpose intended, which is to indicate to the reader the present status of pasteurization.

Present Status of Clinical Tests for Vitamin Deficiency*

Food and Nutrition Section

MOST estimates of requirement for vitamins today are based on determinations of the minimum amount necessary to prevent visible and recognized symptoms of deficiency, plus a factor of safety to cover individual variations. The size of the factor of safety varies with the viewpoint of the estimator. Such estimates when applied in dietary surveys supply a means for detecting gross deficiency but they do not tell adequacy, if we mean by the latter term amounts necessary to provide optimum needs, optimum health. Neither do they take into account the clinician's problem of how to detect and to follow treatment in an individual case.

For real determination of individual needs; for check on the success or failure of a given vitamin therapy regimen, the clinician needs quick and quantitative tests that can be applied to the patient. Such tests are developing and, while still imperfect, they give promise of what the clinician needs, of taking the guess work out of vitamin therapy.

In view of the importance of these tests it seemed best to the committee to present this year a summary of those tests that are in process of development and some of the problems to be solved to make them more efficient.

In general, two factors, at least, determine the individual's needs for

vitamins; the amount ingested and the amounts in storage in the body. To meet this requirement there is coming into general use the test dose method; the giving of large initial doses and determining from the amounts excreted the state of saturation of the individual. For this purpose it is essential that we have means of measuring the blood content of the vitamin as an index of tissue condition and the fecal and urine content of the vitamin to estimate amounts excreted. And even when these data are available we may still have problems of vitamin fate to determine, due to destruction or conversion of the substances in the body.

CLINICAL TESTS FOR VITAMIN A DEFICIENCY

1. *Dark Adaptation Tests*

It is generally agreed that hemeralopia is one of the earliest indications of vitamin A deficiency. The explanation is now shown to be that the regeneration of visual purple necessary to acuity of vision requires a continuous supply of vitamin A.

There are many devices that have been developed to measure this phenomenon, ranging from the use of a watch with a luminous dial to the complicated biophotometer of Frober-Faber, the adaptometer of Feldman, and the machine of Hecht. All, however, accomplish the measurement by first bleaching the visual purple in the rods of the retina with a bright light

* Report of the Committee on Nutritional
Requirements.

and then determining the time necessary to recover clear vision. That the methods truly measure rate of regeneration of visual purple and hence, indirectly the eye's supply of vitamin A is agreed. The test has been used by Jeans¹ who has reported that with the biophotometer he was able to show that an 11 year old boy required 3,000 International units of A per day to prevent hemeralopia. Jeghers,² working with adults and this machine, estimated that the daily requirement was at least 4,000 units of A per day and recommended 6,000 to cover individual variations. On the other hand, Feldman and Ezickson,³ while showing correlation between low dark adaptation tests and cases of urinary lithiasis, failed to correct the hemeralopia in these cases by feeding large amounts of vitamin A. And more recently, Isaacs, Jung, and Ivy⁴ go so far as to say: "Far more study is essential before the biophotometer or any similar instrument can be used *per se* for the detection of vitamin A deficiency in the human being."

It is generally conceded that retinal function is of two types: that of the cones, sometimes called photopic or day vision; and that of the rods, similarly sometimes designated as scotopic or night vision.⁵ The rod vision is known to be concerned with chemical changes in the visual purple and the ability to regenerate this pigment quickly is a function of the supply of A brought to it by the blood. Haig, Hecht, and Patek⁶ have recently pointed out a correlation between cone threshold and rod threshold and suggest that the visual violet of the cones may also be involved in vitamin A chemistry.

Those who criticise the present reports of vitamin deficiency as determined by dark adaptation tests do not quarrel with the above theory. They agree that hemeralopia is an early sign

of A deficiency. But some of these critics hold that the tests as conducted today are frequently not satisfactorily controlled to rule out factors other than A deficiency.

These devices were discussed at a recent meeting of the American Institute of Nutrition and while it was agreed that the test is valuable for sorting out individuals with sub-clinical deficiencies and hence valuable to the health worker in indicating need for dietary measures; for precise determination of subnormal A nutrition the test needs standardization in terms of eye physiology. Necessity for controlling the coöperation of the individual under test, methods of controlling light, standard position for the most sensitive portion of the eye, calibration of the instrument, were some of the features suggested as needing attention.

Feldman⁷ has made a special study of the problem and has devised a new form of adaptometer to control some of these factors. He says that the study indicates that there are at least two types of poor dark adaptation:

1. A definite and serious disturbance of rod structure for which there is no known cure
2. A functional type usually due to a deficiency and usually quite amenable to A therapy.

(Ophthalmoscopic examination is essential for excluding type 1.)

In the Feldman instrument, tests are performed in a dark room. The patient is first exposed to a bleaching out light of controlled intensity and during this period the operator is able to determine whether the eyes are kept open during the entire period; pupil opening is controlled by pilocarpine after the method of Derby.⁸ After the exposure light is cut off, the patient fixes his finger at a protuberance on the machine so located that automatically the light is focused on an area of the eye (20 degrees off fovea) where the rods predominate.

The patient reports not only when he sees clearly the lighted image but also the direction of an image which can be shifted by the operator. This feature insures true response of the patient.

There are other control features, but these are given to illustrate how the test is being studied and corrected to eliminate false conclusions. Feldman reports that individuals recognizing the image and giving its direction in 5 minutes or less are normal as to A supply; those requiring more than 5 minutes are abnormal and if the ophthalmoscopic examination does not show eye pathology, are probably examples of A deficiency.

Like most clinical tests the dark adaptation results need correlation with other means of detecting A deficiency. Such correlation is becoming possible by blood examination tests.

2. Blood Vitamin A and Carotene Tests

Carr and Price⁹ in 1926, developed a quantitative method of measuring vitamin A potency from its color reaction with antimony trichloride. Since the blue plates of the Lovibond Tintometer were used in matching the intensity of the color produced the Carr-Price method results are usually expressed in "Lovibond Blue Units." Correlating such tests with spectrophotometric tests and using a highly concentrated A vitamin preparation British workers reported that they got an "E" value of 1,600 and a blue unit value of 80,000; a ratio of 1/50. Holmes and Corbett¹⁰ with their pure crystalline vitamin A got an "E" value of 2,000 and a blue unit value of 100,000, the same ratio as the British workers. The Holmes-Corbett product bioassayed at 4,000,000 International units per gram. On that basis a blue unit value of 1 would correspond to a unitage of 40 I.U. per gm.

A method of applying the Carr-Price

reaction to blood plasma to detect its vitamin A content has been worked out and used for estimating vitamin A content per 100 c.c. Unfortunately, when one uses this test with vitamin A sources other than the pure or highly concentrated A materials, there are substances that interfere with the test. The color reaction is also transitory and it is difficult to detect the highest intensity attained. For that reason it is probably impossible as yet to use a conversion factor such as 40 I.U. per 1 blue unit of A found in a natural or biological source and be sure that it gives the absolute quantity of A in units. Use of the photoelectric colorimeter, such as devised by Evelyn¹¹ and by others, helps to make the readings more accurate. However the test does give relative results and is useful in detecting whether vitamin A intake is deficient and whether the therapy is being successful in getting the vitamin into the blood stream.

Using this method Menkin¹² has reported variations in blood plasma ranging from 0 to 8.4 blue units per 100 c.c. Eddy, Mackie, and Bach¹³ examined 38 apparently normal individuals before and after breakfast with the results shown in Table I.

TABLE I

Data	Before Breakfast	After Breakfast
No. cases examined	38 (same individuals) 38	
Ave. blue units per 100 c.c.	2.07	2.40
Range	1.0-3.3	1.1-4.4
Standard deviation	.05	.075

May has used the test rather extensively but as yet there is no apparent agreement as to what blood value constitutes a normal or a subnormal condition. We also have as yet little data on the correlation of this test with the dark adaptation test. Such data, when forthcoming, will help to clarify both means of estimating A deficiency.

BLOOD CAROTENE TESTS

Carotene also gives a blue reaction with antimony trichloride and in separating the vitamin A from the carotene values this must be taken into account. Carotene also, because of its intense yellow color may be estimated colorimetrically by extraction and comparison with standards of crystalline beta-carotene, or with dichromate solutions or with the yellow plates of the Lovibond Tintometer. When the latter are used as reference, results are given in "Yellow Units." Ferguson¹⁴ has worked out a curve for converting yellow unit values into milligrams of carotene which may be used in this test.

Data on blood carotene content are a little more extensive than on vitamin A values. Clausen¹⁵ in 1933 used this test to determine the effect on infection of the vitamin A potency of the blood. He states that he found the normal carotene level in children over 2 years of age to be fairly constant at .08 mg.%. Heyman¹⁶ using the method of Connor¹⁷ showed that the blood carotene content of diabetics was definitely higher than that of normal individuals. He gives these values for 7 normal healthy children: .08, .08, .08, .152, .140, .421, .182 mg.%. Connor himself¹⁷ reported that 3 c.c. of plasma is enough for the test and that he got from three normal persons .0, .04, .07 mg.% as against .05 to .16 mg.% in diabetics. He also quotes Van den Bergh, *et al.*¹⁸ as finding .4 to 1.34 mg.% in normal individuals and .45 to 1.9 mg.% in diabetic blood. Ralli, *et al.*¹⁹ report the fasting value for 4 normals as .145 mg.% against .145-.200 mg.% in 4 diabetics. Kaufmann and Drigalski²⁰ report estimation of carotene in 1,000 cases. They found 85 per cent to show less than .01 mg.%; of the other 15 per cent, the variation was to a maximum of .270 mg.%. Using the same individuals who took

the vitamin A test Eddy, Mackie, and Bach¹³ got the results shown in Table II.

TABLE II

<i>Data</i>	<i>Before Breakfast</i>	<i>After Breakfast</i>
No. cases	38	38
Ave. yellow units	.83	.97
Range	.3-2.7	.5-4.1
Standard deviation	.043	.06

Using the Ferguson curve to translate the yellow units into milligram per cent, the results show an average fasting value of .045 mg.% against an after breakfast average of .052 mg.%.

Correlating these tests with the A results they seem to justify the following conclusions:

1. Carotene content is not only usually less than A content but it is less variable.
2. There is no constant relation or ratio between carotene and A content of the blood.
3. Food intake produces a more immediate effect on the blood A content, affects carotene level less.
4. Single determinations are probably misleading in estimating the individual's saturation with A or carotene and repeated estimations of fasting levels on successive days probably give a truer picture of condition.

These conclusions appear to be supported by the observations of others²¹ who have reported on this test.

These tests are applicable to urine and have been made. There are few data on fecal tests. In general it appears that the normal person excretes practically no A in the urine. When such a test is positive, it indicates a serious condition in the patient. Cancer cases and tuberculous and general infection cases have shown urinary elimination of the vitamin.

The value of the test in following vitamin A therapy was strikingly illustrated by one ulcerative colitis case of Eddy and Mackie. This individual had been receiving 39,900 units of A by mouth for a considerable period with absolutely no rise in blood A. The

patient was put on topical application of cod liver oil (3 tablespoons twice a day rubbed into the chest). In 3 days, the blood A began to rise, proving beyond doubt the blockage of the path of absorption from the gut and incidentally indicating another route possible to restore blood supply. For following vitamin A therapy, the test has already proved its value.

CLINICAL TESTS FOR VITAMIN B₁ DEFICIENCY

In this field the most widely studied test is that based on a conversion of thiamin into thiochrome, the latter having a blue fluorescence whose intensity is measurable by colorimetric methods.

Formula for Thiochrome

This compound is producible by the action of potassium ferricyanide on thiamin or on the co-carboxylase, thiamin-pyrophosphate.

The principles involved in making this test are: (1) the extraction of the B₁ from the urine by an adsorbent, then the removal of the thiamin from the adsorbent by a suitable reagent.

Then conversion of the thiamin into thiochrome, production of fluorescence by ultra-violet irradiation and measurement of the intensity in contrast to standard solutions of thiochrome.²² In his adaptation of the test, Pyke²³ used the Cohen²⁴ fluorimeter.

In the hands of Westenbrink, Goudsmit, Jansen and coworkers²⁵ this test has given very satisfactory results in the determination of the B₁ content of urines. They adsorb the vitamin from a small sample of urine (about 6 c.c.) which is then diluted to 50 times with pH3 water and the B₁ removed with franconite (special form of Fullers earth). A feature of their recovery of B₁ from the franconite without destruction is their use of a small amount of methyl alcohol with the alkali and the prevention of oxidative changes by bubbling CO₂ or N₂ during the treatment. The thiochrome, when produced by the alkali ferricyanide, is gotten into solution in isobutanol. Jansen has designed a special fluorimeter after the Cohen type but with a filter between the activating lamp and the tube of thiochrome that concentrates the ultra-violet rays and another filter between the fluorescing thiochrome and the photoelectric cell so that the latter is affected solely by the visible rays of the fluorescing thiochrome.

The Dutch workers have reported results such as shown in Table III, as

TABLE III

Diets	Dates 1937	Gamma of Thiamin Excreted		
		9 A.M.-9 P.M.	9 P.M.-9 A.M.	24 Hr. Total
1. Normal plus 5 mg. thiamin given 1 mg. @ 9 A.M., 1 P.M., and 6 P.M.	4/20-21			
2. Ditto	4/21-22	290	170	460
3. Normal diet without the added thiamin	4/22-23	390	160	550
4. Ditto	4/23-24	80	40	120
5. Normal diet plus 3 mg. thiamin given 1 mg. @ 9 A.M., 3 P.M., 9 P.M.	4/24-25	30	10	40
		160	160	320

evidence of the value of the test in following changes in B_1 intake.

Their results check with those of Helmer.²⁶ Harris and Leong²⁷ have reported the normal B_1 excretion as from 12 to 13 I.U. daily and an amount less than 12 indicating inadequacy of B_1 intake. It is now generally agreed that 3 gamma of thiamin corresponds to 1 I.U. of B_1 . This would mean that 12 units corresponds to 36 gamma. It checks with figures the Dutch workers get on the normal diet.

In a recent paper Goudsmit²⁸ makes the following comment on their results which is perhaps worth quoting:

Two subjects excreting normally 100 gamma or more of aneurin daily (aneurin is the continental name for thiamin) were dosed with 5 mg. aneurin during several days. During this time they always excreted the same amount of aneurin which indicates they were saturated with aneurin.

The mean excretion of 10 men who were living on a very good diet was 230 gamma in 24 hours; after uptake by mouth of 5 mg. aneurin they excreted on an average 560 gamma in 24 hours. Ten women living on the same diet but eating much less excreted on the average 120 gamma in 24 hours and after the uptake of 5 mg. aneurin by mouth 460 gamma in 24 hours.

From a certain amount of aneurin given by mouth a larger part is excreted when it is given in several small doses than when it is given in one large dose; so from a larger dose a lower percentage is excreted than from a smaller dose. The excretion is higher after intramuscular injection of larger doses of aneurin than after the uptake by mouth of the same doses; the difference increases with increasing doses. The difference is only evident in the first hour after the uptake of aneurin; no difference was observed in the next hours. Obviously, the high excretion during the first hour after the injection is caused by a temporary, abnormally high aneurin concentration in the blood.

Further, we may conclude from the experiments that the aneurin is not destroyed in the gut or to a very slight degree. Moreover these results show that a saturation test of patients and other subjects must be carried out by giving the aneurin by mouth and not parenterally. The application of both testing methods to some patients confirmed this view.

A distinct influence of pregnancy on the excretion of aneurin was observed; pregnant women excreted on the average, as well without as with an extra dose of aneurin, considerably less aneurin than non-pregnant women, who might be expected to be living on the same diet. With very few exceptions, the pregnant women were far from saturated with aneurin. Among 20 pregnant women, originating from the poorer classes of the Amsterdam population, there was a group showing several symptoms. The excretion of aneurin of the first group was higher than of the second group, and its food intake was more adequate.

In this country the thiochrome test has been studied by Cerecedo and Hennessey²⁹ using zeolite as the adsorbent and a special fluorimeter. They note that if the co-carboxylase is present and remains in the aqueous layer during isobutanol extraction of the thiochrome the method will give lower values than the bioassay. This can be corrected by kidney extracts which on incubation convert the co-carboxylase by hydrolysis. Or, one can use the method of Jansen.³⁰ Jolliffe has also devoted study to this test but as yet has not published his findings.

Prebluda and McCollum³¹ have coupled thiamin with para-aminoacetophenone to form a red dye, estimable colorimetrically. Melnick and Field³² report the use of this test with urines. In that connection Dr. Prebluda sent me the following letter which I insert in the matter of information on the status of this test.

"I have just received a letter from Dr. Melnick and thought that you would be interested in the following excerpt in connection with a rapid chemical test method for urine involving the use of our reagent:

"I am happy to be able to tell you of our success with the application of your reagent to the chemical determination of vitamin B_1 in biological materials. We can now assay accurately and very rapidly extracts of rice polish, wheat germ, liver and yeast. As you well know, vitamin B_1 exists in biological materials both as co-carboxylase and as free thiamin. No chemical method has been able to pick up the B_1 activity due to the

presence of co-carboxylase in the preparation. However, we have also developed a quantitative procedure for the conversion of the phosphorylated vitamin into free thiamin. By difference we can now estimate chemically the co-carboxylase content of various preparations. In addition, we have also been able to apply the method to urine analysis. We expect to devote the major portion of the coming year to problems of clinical interest dealing with vitamin B₁ metabolism.'"

Several others³³ have suggested color tests dependent upon coupling thiamin with color producing reagents but none of these tests have as yet been sufficiently extended to judge of their efficiency.

THE YEAST FERMENTATION TEST

Another urine test that promises value has been developed by Schultz, Atkin, Frey, Light and coworkers.³⁴ This test measures the B₁ content of biological materials by their effect on the alcoholic fermentation of yeast. On a normal diet the average daily urine output by this method was found to be 497 ± 47 gamma for adults and 333 ± 60 gamma for children. With added B₁ in 5 to 10 mg. doses they got variable results and found that much B₁ passed out in the feces (see Table IV). The importance of the fecal determination in determining saturation is obvious from these results.

TABLE IV

Ave. daily excretion on 2nd and 3rd days on normal diet plus 10 mg. B ₁
Subj. D: In urine 2,350 gamma; in feces 7,360 gamma
Subj. F: In urine 2,600 gamma; in feces 6,900 gamma
Ave. daily excretion on 2nd and 3rd days after reducing doses to 5 mg. B ₁
Subj. D: In urine 2,600 gamma; in feces 2,210 gamma

This method is not absolutely specific for B₁³⁵ but is simple to operate and offers a good method for following vitamin B₁ therapy.

We have been unable to find any results to date on the blood content

of B₁. Farmer has stressed the importance of having all the determinations, blood, feces, urine, to arrive at satisfactory indication of saturation. We do have a test for pyruvic acid content of blood (by Clift and Cook).³⁶ Platt and Lu showed³⁷ that in beriberi there is an increase in this acid in the blood due to failure of oxidation from lack of B₁. Johnson, *et al.*³⁸ have developed from the Clift and Cook procedure a quantitative method for determining blood pyruvate. The method consists in measuring the bisulphite binding substance in the blood. Johnson, *et al.* report that the normal content of blood averages 2.81 mg. pyruvic acid per 100 c.c., range 1.96 to 4.00 mg.% in 22 cases.

THE BRADYCARDIA TEST

This test has been used as developed by Drury, Harris, and Maudsley³⁹ for estimating food content of B₁ but has not been well adapted for clinical purposes.

MATHEMATICAL FORMULA OF COWGILL

Cowgill⁴⁰ has reduced the expression of B₁ needs of the human being to a mathematical formula which in revised form and on the basis that 1 I. U. of B₁ is 3 gamma, is as follows:

Int. Units B₁ required equals:

$$.00142 \times \text{wt. in kg.} \times \text{calorie intake}$$

Of this formula Cowgill says⁴¹:

"It should be emphasized that estimates of the human requirement for B₁ derived from my formula pertain to the minimum or beriberi-preventing level; the optimum intake is undoubtedly much greater."

CLINICAL TESTS FOR VITAMIN C DEFICIENCY

Blood and urine tests for vitamin C have attained far greater study than those for other vitamins, and Farmer⁴² has reviewed the subject in the *J.A.M.A.* recently. He has also kindly supplied data from his unpublished material to

illustrate some of the problems still to be solved. Incidentally, he cautions against the use of cyanide in blood treatment as affecting the titration for ascorbic acid content.

The most used test is that of Farmer and Abt.⁴³ By this method Farmer estimates from his collected results that a blood content of .5 mg.% or lower is indicative of active scurvy. That between .5 and .7 is the prescurvy range. Amounts over this with an average around 1 mg.% are probably indication of adequate supply.

Using this method Eddy, Mackie, and Bach¹³ tested the blood of 88 apparently normal individuals and individuals whose statement of diets indicated a good supply of C. Of these, however, the blood test showed 25 per cent to have a blood ascorbic acid content of less than .5 mg.%. Of the 63 individuals above .5 mg.%, the average blood figure was 1.06 mg.%, in agreement with most observers as indicating satisfactory saturation. The standard deviation in this series was .37 mg.%.

King⁴⁴ puts the normal at 1.2 mg.%. He considers, like Farmer, a value below .5 mg.% as indicative of C deficiency. Eekelen⁴⁵ and Heineman⁴⁶ have pointed out that the amount of C in urine and in blood depends upon at least two factors: the amount ingested and the amount stored in the body. They considered saturation indicated by a blood concentration of 1.13 mg.% or higher. Ingalls and Warren⁴⁷ call 1.15 mg.% normal. Bauman⁴⁸ found the fasting value of saturated individuals to range from .45–2.5 mg.%. Neuweiler⁴⁹ considers that a blood C of 1 mg.% indicates the body well saturated. He reports that of those showing .6–.75 mg.%, 50 per cent had hypovitaminosis C; of those showing .8–.95 mg.%, 27 per cent showed a slight hypovitaminosis C. Hypovitaminosis was severe in all cases showing .6 mg.% or less.

Chu and Sung⁵⁰ reporting on the blood values for normal and sick children put .85 mg.% as indicating saturation; .5–.8 mg.% as presaturation stage; and below .4 mg.% as indicating deficient C metabolism. All breast fed infants examined by them had higher than .5 mg.% and all infants artificially fed, plus little or no cabbage water, ranged from .168 to .342 mg.%. They found plasma C low in acute bacillary dysentery even with large intakes, in kala-azar and in tuberculosis.

Nielsen⁵¹ using the methylene blue test (similar to Emmerie's test) found in 100 supposedly normal individuals on the normal Danish diet examined between April and May a low of .3 mg.%, and the highest value obtained was in September and reached .4 mg.%. They found blood C low in gastric and duodenal ulcer cases.

In a discussion reported in *J.A.M.A.*, February 26, 1938, Spellberg and Keeton reported 1.18 mg.% or higher for normal patients. Rinehart, *et al.*⁵² showed a low blood C in rheumatoid arthritis.

Eddy, Mackie, and Bach¹³ applied the test to 27 cases of varying degrees of ulcerative colitis. Of these only 7 showed a blood C below .5 mg.%. Thirteen were below the presaturation value of .8 mg.%; 7 averaged 1.0 mg.%. These results emphasize the importance of actual tests rather than generalizations that a given disease is certainty of C deficiency.

Before discussing Dr. Farmer's results we may note the status of urinary tests for C elimination.

Harris and Ray⁵³ suggested testing excretion of vitamin C in urine with and without test dose as a criterion of body saturation with vitamin C. They noted that if the daily excretion fell below 25–30 mg. in 24 hours there was a probable C deficiency, but since the amount varies with the intake and other factors they suggested giving a

test dose. On such a procedure the saturated individual shows a sudden peak of excretion after the test dose; the unsaturated individual does not, as his tissues are assumed to take up the dose and the peak is lacking or lower. King⁴⁴ puts it that the net loss between intake and excretion for a person in state of saturation may be taken as an approximation to the quantity normally destroyed or "burned" in the body daily; that it falls usually between 25 and 50 mg. The following results from the Eddy, Mackie tests¹³ illustrate the effect of the test dose method:

Case Record

Test dose: 500 mg. ascorbic acid by mouth in 500 c.c. water at 9 A.M.

Excretion results:

Time: 11 A.M. 6.3 mg. in 65 c.c. urine
1 P.M. 18.1 mg. in 260 c.c. urine
3 P.M. 9.1 mg. in 135 c.c. urine
5 P.M. 10.2 mg. in 90 c.c. urine

Total 43.7 mg. in 6 hours; less than 10 per cent of the test dose.

There is a general tendency today to consider that unless 50 per cent or more of the test dose is promptly eliminated the individual is not in saturation.

Dr. Farmer⁵¹ however, suggests that his studies indicate that this reliance on per cent of C excreted in urine after test dose is not reliable unless one determines at the same time blood and fecal values. The following case record from his files illustrates his point.

Case record of Farmer (cancer case)

Patient on entering hospital had a blood C of .16 mg. % and a urinary elimination of 16.5 mg. in 345 c.c. urine. A routine intravenous injection of 1,000 mg. ascorbic acid daily was begun on October 11, in the hospital. The tests on this patient on subsequent days with 1,000 mg. injections daily are shown in Table V.

Two observations are noteworthy in this case: (1) The blood values as indication of saturation fail to correlate

TABLE V

Date	Blood C mg. %	Urinary C mg. in c.c. urine	Fecal C mg. gm.
Oct. 12	1.42	630.08	1,560
13	1.01	531.28	1,160
14	1.50	281.18	1,845
15	1.05	111.0	1,480
16	406.7	1,500
17	1.05	565.76	442
18	0.97	385.53	1,810
19	1.27	626.45	1,340
20	Surgical	operation on this day	
21	0.75	668.1	2,320
22	0.90	588	1,960
23		1,210 in 2,485 c.c. on Oct.	
24	1.32	23 & 24, or 605 per day	

with the per cent of test dose excreted in the urine. (2) The failure is not due to fecal elimination but some factor as yet undetermined.

Contrast these data:

Date	Amt. C Injected mg.	Blood C mg. %	Urine C mg.	Fecal C mg.
Oct. 14	1,000	1.50	281.18	0.94
Oct. 17	1,000	1.05	565.76	1.70
Total Urine and Fecal Excretion			Per cent Ingested that Was Excreted	
Oct. 14: 282.12			28	
Oct. 17: 567.46			57	

What is the true index of saturation? On October 17, the excretion in urine is greater than the blood value on October 14, but the blood value indicates better saturation on the 15th, than on the 16th.

Farmer notes another problem still unsolved. On a constant daily dose the blood level does not stay constant. The case given above illustrates this and also the following from Farmer's records:

Case record (Farmer):

Amt. test dose was 1,000 mg. ascorbic acid daily.

Date	Blood C mg. %	Urine C mg. in c.c. urine	Fecal C mg. gm. feces
9/9	0.24		
9/23	0.88	763.8 in 1,900	4.43 in 110
10/3	0.68		
10/10	0.92		
10/21	0.57		

Why these variations? Failure to recover in urine and feces does not prove utilization in tissues. There may be other factors involved and the 50

per cent elimination criterion as an index of saturation does not hold.

There are, in brief, still problems to solve as to the fate of C even if we have urine, fecal, and blood values.

THE INTRADERMAL TEST

Rotter,⁵⁵ basing his procedure on observations of the discoloration of phenol-indophenol dye when injected into the soles of guinea pig feet, came to the conclusion that the decolorization of the dye could be taken as an indication of tissue saturation with C when the dye was injected under the epithelium.

Portnoy and Wilkinson⁵⁶ confirmed his observations using the method with human subjects. They stated that 5 minutes or less for decolorization meant saturation; 10 minutes or more meant scurvy.

Poncher and Steubenrauch,⁵⁷ on the contrary, have been unable to find such a consistent relation between blood C values and intradermal test results. They report the test to lack sufficient specificity to make it a reliable index of saturation.

THE CAPILLARY RESISTANCE TEST

The principal exponent of this test in this country is Dalldorf⁵⁸ and in Sweden, Göthlin.⁵⁹ Others⁶⁰ have had variable experience with the test; some getting good correlation, others poor

checks. The test measures the fragility of the capillary and when that fragility is due to lack of C the test is specific for C deficiency. Unfortunately, there are other factors than C which affect the bleeding tendency and the test is therefore not specific.

Using the instrument designed by Dalldorf⁵⁸ Eddy, Mackie, and Bach¹³ got the type of comparisons with blood C values shown in Table VI.

In this series it will be noted that those with the greatest number of petechiae were in the low blood C group. It is also true however, that those with high blood C did show some petechiae and two, a surprisingly high fragility.

The test is useful in surveys for checking possible C deficiency but needs check against other tests to prove actual scurvy.

CLINICAL TESTS FOR VITAMIN D DEFICIENCY

Jeans and Stearns⁶¹ preface their discussion of vitamin D requirements with the following statement:

"The requirements of vitamin D may be defined as those amounts which, with ample intakes of calcium and phosphorus and a diet otherwise adequate, insure sufficient retention of calcium and phosphorus to permit (a) normal growth and mineralization of the skeleton and teeth of infants and children, (b) maintenance of the bony and dental structures during adult life, and (c) a sufficient supply for mother and infant during pregnancy and lactation."

On this basis they recommend 300 to 400 units per day for all groups except the pregnant and lactating mothers, and for them 800 units. They are uncertain as to normal adult needs but suggest 300 to 400 units.

Park⁶² under the heading of "How to gage the success of vitamin D therapy" makes the following pertinent comment:

"One can assume that preventive treatment is succeeding if the signs of rickets do not make their appearance in the roentgenogram of the radius and ulnar . . . if the level of the

TABLE VI

Group I Individuals with Blood C Below .5 mg. %		Group II Individuals with Blood C Above .5 mg. %	
No. Petechiae *	Blood C mg. %	No. Petechiae *	Blood C mg. %
35	.001	4	.6
25	.04	17	1.72
30	.05	7	2.10
24	.07	14	2.8
16	.08 (3 cases)	5	2.97
26	.09	3	3.5
8	.14	7	3.85
5	.16	2	4.5

* Petechiae at 30 cm. mercury negative pressure

calcium of the serum remains above 9 mg. % and that of the phosphorus above 5 mg. %."

X-ray and blood Ca and P determinations are then the most commonly used clinical tests for adequacy of vitamin D in the prevention of rickets.

Park also suggests that the blood tests are valuable in detecting effect of overdose:

"The rule holds that the dose of D will not become toxic so long as the calcium and inorganic phosphorus levels in the blood are not affected. Apparently toxic action does not depend upon the level of vitamin D in the blood but upon its effect on the calcium and phosphorus metabolism."

Table VII gives an idea of the range of blood values in normal and rachitic types.

TABLE VII

Condition of Patient	Mg. % P	Mg. % Ca
1. Rachitis, no D	3	7
2. Normal with D	4-5	10
3. Hypervitaminosis D	8	15

Another method of using the blood figures on Ca and P for diagnosis is to multiply one by the other getting the Ca x P product. In general a product under 30 indicates rickets.

There is, however, increasing feeling that the blood P value and the X-ray tests do not detect satisfactorily the incidence of rickets or normal healing. For that reason other indices have been sought and at present the blood phosphatase content appears to be a means to better diagnosis.

THE BLOOD PHOSPHATASE TEST

Harris⁶³ says:

"... Another and more recent method depends on a measurement of the amount of the ferment, phosphatase, present in the blood. This is normally a constituent of the growing bone but when the bone is diseased as in rickets it leaks out into the blood in increased amounts. As the bone becomes healed, less phosphatase is found in the blood again."

Kay⁶⁴ has reviewed rather com-

pletely the rôle of phosphatase in the growth and disease of bone and has developed a test⁶⁵ for its presence and amount in the blood.

Some values reported by Kay⁶⁴ are given in Table VIII.

TABLE VIII

Disease	No. Cases	Phosphatase Highest	Content of Plasma Lowest	Average
None (normals)	33	.21	.08	.14
Rickets infantile	13	1.7	.42	1.03
Osteomyelitis	8	.41	.14	.27

More recent reviews of the subject have been made by Morris, Peden, and associates.⁶⁶ There are several methods of test devised which differ in method of expressing phosphatase values. Table IX shows results with 6 different tests from Morris and Peden's review.

TABLE IX

Method of Test	Normal Phosphatase Values in Units			
	Adults		Children	
	Max.	Min.	Max.	Min.
Bodansky ⁶⁷	4.0	1.5	12.0	5.0
Cayla ⁶⁸	15.0	10.0	40.0	35.0
Jenner-Kay ⁶⁹	7.9	3.2	11.0	3.4
Kay ⁷⁰	0.21	0.10	0.34	0.17
King-Armstrong ⁷¹	13.1	3.7	20.0	15.0
Roberts ⁷²	5.5	3.0

Morris and Peden report a study of 506 children below 2 years of age. In 84.1 per cent of the cases with clinical or X-ray evidence of rickets the plasma phosphatase was increased above the normal limits. They believe that the phosphatase rise is an earlier manifestation of the rachitic state than is provided by the ordinarily applied clinical or roentgenological tests. They show that the addition of vitamin D produces a prompt fall in the phosphatase, roughly proportional to the size of the dose. The test therefore, becomes an index of the success of vitamin D therapy.

Barnes and Carpenter⁷³ have also reported a study of this test with a large number of infants. They say:

"Serum phosphatase test appears to offer an excellent measure of rachitic activity and

a means of determining the rate and progress of healing."

There is at present some difference of opinion whether the healing of rickets is complete when the phosphatase has returned to normal. Bodansky and Jaffe⁷⁴ take the affirmative view, while Barnes and Carpenter question it. The latter suggest that treatment should be continued for some time after the normal level has been reached to insure complete healing.

Clinical tests for the other vitamins are not yet developed to a point where one can make comment. Those listed in this report need further study. It is the purpose of the report to supply suggestion of matters that need study, for exactitude in vitamin prescription must await the perfection of such tests.

Standard Methods of Vitamin D Bioassay of Milk

Food and Nutrition Section

THE method herein described incorporates the principles of the method outlined in the *U. S. Pharmacopocia*, Volume XI, page 478, for the vitamin D assay of cod liver oil. Terms herein used are defined in the U.S.P. XI. Subsequently, the Association of Official Agricultural Chemists¹ adopted tentative methods for the bioassay of vitamin D milks. Certain modifications of the U.S.P. method suggested by the A.O.A.C. when assaying vitamin D milks, are entirely optional with the assayer.

COLLECTION AND PRESERVATION OF THE SAMPLE

Wherever possible the sample of milk in the original bottle should be delivered to the assayer immediately after collection, or stored in a refrigerator until delivered. Shipments should be made in iced containers. Experience has demonstrated that dry ice is not suitable for shipping purposes unless very carefully packed. Even during the summer season the supercooling effect of dry ice in many instances causes the milk to freeze, resulting in the bottles cracking and a total loss of the sample. Shipping containers with icing pans (using ordinary ice) are preferable.

After acceptance by the assayer, the milk may be preserved in its original homogeneous state (a) by ordinary refrigeration (40° to 50° F.) for a period of not more than 1 week to 10

days, (b) for a period of not more than 30 days by the addition of two drops of 10 per cent formalin and ordinary refrigeration. Once a sample of milk becomes soured or curdled, it is unsuitable for assay purposes. Obviously, collection and preservation of evaporated or dried milk samples present no special problems; however, once they have been submitted to the assayer and opened, precautions with respect to preservation outlined above must be followed.

PRELIMINARY PERIOD

Rats suitable for test as standard rachitic rats may be prepared as follows: They must be born of and reared by rats kept on a stock ration low in antirachitic potency until they have attained an approximate weight between 45 and 60 grams at an age of 21 to 28 days.

A ration suitably low in antirachitic potency for this purpose has the following composition.

Yellow maize	71.0
Linseed oil meal	16.0
Crude casein	5.0
Alfalfa meal	2.0
Butter fat	5.0
Bone ash	0.5
Sodium chloride	0.5
Fed with fresh whole milk and water <i>ad lib.</i>	

If it is not convenient to use fresh milk, the diet may be modified as follows:

Yellow maize	57.0
Whole milk powder	25.0
Linseed oil meal	12.0
Crude casein	3.7
Alfalfa leaf meal	1.5
Iodized sodium chloride	0.4
Calcium carbonate	0.4
With water <i>ad lib.</i>	

All the solid constituents of the ration must be finely ground to prevent selection by the animals.

Throughout the preliminary period, each rat shall be raised under the immediate supervision of or according to directions specified by the assayer. Throughout the preliminary period, the rats, if maintained on either of the above dietary regimens, will be provided for normal development in all respects. The supply of vitamin D in the diets as listed is sufficient for maintenance needs and is limited to such a degree that rats weighing between 40 and 60 gm., at an age of 21–28 days, when placed on a suitable rachitogenic diet for 3 weeks will manifest evidence of severe rickets.

DEPLETION PERIOD

When the rats as produced above have reached the weight and age range above indicated, they are made standard rachitic rats by transference to and maintenance on a very finely ground rickets producing diet. Formulae for a suitable rachitogenic diet are given below.

McCollum Diet 3143²

1. Whole yellow maize ground	33.0
Whole wheat ground	33.0
Ground gluten	15.0
Gelatin	15.0
Calcium carbonate (CaCO_3)	3.0
Sodium chloride (NaCl)	1.0

Steenbock Diet 2965³

2. Whole yellow maize ground	76.0
Ground gluten	20.0
Calcium carbonate (CaCO_3)	3.0
Sodium chloride (NaCl)	1.0

It is advisable that each new lot of ration be used in a preliminary way

to determine whether it produces satisfactory rickets.

A rat shall be suitable for the depletion period when the age of the rat does not exceed 30 days, and if the body weight of the rat shall exceed 44 gm. and does not exceed 60 gm., and if the animal manifests no evidence of injury or disease or anatomical abnormality which might hinder growth and development. Throughout the depletion, each rat shall be provided with the rachitogenic diet and distilled water *ad lib.*, and during this period no other dietary supplement shall be available to the animal.

Throughout the depletion and subsequent assay period, the rats shall be maintained on wire screens in a room away from direct or reflected sunlight of sufficient intensity to influence rickets in the rat. A range of temperature between 72 and 80° F. is most suitable for the care of the animals during the depletion and subsequent test period as well.

ASSEMBLING RATS INTO GROUPS FOR ASSAY PERIOD

Rats which are suitable for the assay period shall be assembled into groups; for each milk assay there shall be one or more assay groups. In the assay of one vitamin D milk, there shall be provided at least one reference group, but one reference group may be used for the concurrent assay of one or more vitamin D milks. During the interval of assembling rats into groups, the total number of rats that shall have been assigned to make up any one group shall not exceed by more than 2 the number of rats that shall have been assigned to make up any other group. For a given sample, no less than 7 rats should be used, whereas 10 or more rats per given assay will reduce the error due to variation.

When the assembling of all groups shall have been completed, the total

number of rats in each group shall be the same. Not more than 3 rats from one litter shall be assigned to the assay group unless an equal number of rats from the same litter are assigned to the reference group.

In the reference group already mentioned, standard U.S.P. reference cod liver oil shall be used as a comparative standard for the vitamin D assay of milk. During the assay period the reference group shall receive separate from the rachitogenic diet ether extracted skim milk powder equal in weight to the solids not fat contained in the milk fed the assay group. This supplement shall be fed daily during those days of the assay period that the assay groups receive milk.

ASSAY PERIOD

A rat shall be suitable for the assay period, provided the depletion period shall have exceeded 18 days and shall not have exceeded 25 days, and provided a rat shall manifest evidence of rickets. The presence of rickets may be established by examination of a leg bone of one member of a litter by the "line test" described below or by X-ray examination of the animals selected for assay.

Rats suitable for the assay period are weighed and segregated in individual cages provided with screen bottoms, and shall be provided with the rachitogenic diet and distilled water *ad lib.* On any calendar day of the assay period, the assay and reference groups shall receive a rachitogenic diet compounded from the same lot of ingredients.

The assay period shall be 7 days. Throughout the first 6 days of the assay period, each rat in any one assay group shall be fed daily the calculated dose of vitamin D milk, and throughout the first 6 days of the assay period each rat in any one reference group shall be fed daily a dose of reference

oil, except that the following deviation from the daily feeding shall be permissible: that the daily dose of milk or reference oil may be doubled on the day preceding a one day holiday falling within the first 6 days of the assay period. At the termination of the assay period, each rat shall be killed by suitable means and one or more leg bones examined for healing of the rachitic metaphyses according to the line test described below.

The reference oil is diluted before feeding with an edible vegetable oil free from vitamins A and D. The diluted oil shall be stored in the dark at a temperature not exceeding 50° F., and the duration of this storage shall not exceed 30 days. Not more than 0.1 c.c. of the diluted reference oil shall be fed as a daily dose. Inasmuch as the dose of the reference oil required to give a standard narrow continuous line of healing may vary from laboratory to laboratory, depending upon conditions, the dose of reference oil to be fed shall be determined prior to the running of routine assays. By way of orientation, it may be said that a supplement falling between $\frac{1}{2}$ and $\frac{2}{3}$ U.S.P. unit of standard per day (U.S.P. reference oil) will be found to produce a narrow continuous line of calcium deposits in approximately three-fourths of the test animals. It is advisable to use the minimum amount of U.S.P. reference oil required to produce this degree of healing for comparison. The reference oil shall be diluted so that one-sixth of the dose determined to produce positive macroscopic evidence of calcification shall be administered each day for the first 6 days of the assay period.

PREPARATION OF STANDARD TO GIVE $\frac{1}{2}$ TO $\frac{2}{3}$ U.S.P. UNIT

Sample Calculation

Assuming that the reference oil contains 95 U.S.P. units per gm., then 1

unit is contained in 10.52 mg. If $\frac{1}{2}$ unit of oil is fed daily, 5.26 mg. of reference oil shall be diluted with 94.74 mg. of edible vegetable oil so that $\frac{1}{2}$ unit is contained in 0.1 gm. of the diluted oil. Inasmuch as the above dose is for one rat for one day, it is suggested that at least 50 or 100 gm. be prepared. This should suffice for any number of assays performed during a current 30 day period. If 100 gm. is the amount chosen, 5.26 gm. of reference oil shall be diluted with 94.74 gm. of the edible vegetable oil. For $\frac{2}{3}$ U.S.P. unit daily, 7.02 mg. of reference oil shall be diluted with 92.98 mg. of edible vegetable oil. From the amount of U.S.P. reference oil determined to be necessary to produce positive macroscopic evidence of calcification, the calculated amount of milk based on the unitage claimed is fed during the first 6 days in 6 equal doses. If $\frac{1}{2}$ unit per day for 6 days (3.0 U.S.P. or 31.56 mg.) is necessary to produce the type of calcification above described, then the dose of vitamin D milk which would be expected to produce a degree of calcification equal to or greater than the degree of calcification obtained in the reference group may be calculated.

For a vitamin D milk carrying 200 U.S.P. units per qt., this amounts to $\frac{3}{200}$ of 946 c.c. in 1 qt., or 14.14 c.c. total dose; if fed in graded doses during the first 6 days, $14.14 \div 6 = 2.35$ c.c. daily. A vitamin D milk carrying 400 U.S.P. units per qt. would require just one-half, or a total dose of 7.07 c.c. administered at a level of 1.18 c.c. for 6 days. If a higher increment of U.S.P. reference oil is required then the amount of milk to be fed, based on unitage claimed may be calculated. In the method just described, the milk shall be fed in small dishes separate and apart from the diet, and the reference oil may be fed in the same manner or by calibrated dropper or pipette.

The Association of Official Agricultural Chemists adopted a tentative method for the vitamin D assay of milk.⁴ Inasmuch as certain options or alternatives are permitted, it may be said that there are no objections to following the alternatives outlined in the A.O.A.C. if one chooses to do so.

Explanatory Note: Experimental trials and the experience of those now conducting routine assays of vitamin D milk show that departures from the U.S.P. XI method may be made in the manner in which the milk sample and the reference oil are fed, and in the length of the assay period.

If it is necessary to feed a relatively large quantity of milk, a single feeding may not be possible, and daily feedings for a period of days are necessary.

The extent of calcification at the end of a 7 day assay period is not as marked as at the end of a 10 day period. Hence it may be necessary to feed higher levels of milk and reference oil to obtain an adequate response at the end of a 7 day period.

As has been indicated, if use is made of any of the alternatives described, the dose of reference oil and milk will have to be calculated according to the chosen option. In any event, both the U.S.P. reference oil and the milk sample must be fed according to the same plan.

LINE TEST

The effect of the milk feeding and response to the U.S.P. reference oil is determined as follows: The line test shall be made on the proximal end of the tibiae or distal end of the radii or ulnae. The end of the desired bone is removed from the animal and cleaned of adhering tissue. A longitudinal median section shall be made through the end of the bone with a clean sharp blade to expose a plane surface through the junction of the epiphysis and diaphysis. In one assay, the same bone of all the animals must be used and sectioned through the same plane. Both sections of the bone shall be rinsed in distilled water and shall then be immersed in a 2 per cent aqueous solution of silver nitrate for 1 minute. The sections

shall then be rinsed in distilled water, and the sectioned surfaces of the bone shall be exposed in water to daylight or other source of actinic light until the calcified areas have developed a clearly defined stain without marked discoloration of the uncalcified area. Evidence of congestion in the rachitic metaphyses should be clearly distinguished from calcium salts stained with silver, as the principal criteria of healing are the development of the line at the zone of provisional calcification.

As an optional procedure, the bone after being removed and sectioned may be placed in 10 per cent formalin or 95 per cent alcohol for a period of 3 to 4 hours, after which it is rinsed in distilled water and stained with silver nitrate in a manner previously described. The use of this modification is purely optional; however, the bone specimens seem to stain more distinctly, the tissues harden and clear. The small time that the specimen is resident in the formalin is too short to cause any significant decalcification due to formic acid. If longer periods of storage are used 95 per cent alcohol is preferable. Other modification of the staining technic may be used providing they are equally satisfactory in showing calcified areas.

RECORDING OF DATA

Records shall be made immediately after staining of the extent and degree of calcification of the rachitic metaphyses of every section. Numerical values shall be assigned to the extent and degree of calcification of the rachitic metaphyses of the bones examined by the line test so that it will be possible to average the performance of the group. Assayers using the distal end of the radii and ulnae shall follow the method described by Dyer⁵ when evaluating numerically. If the tibia is used the method described by Bills⁶ should be followed. On the day be-

ginning the assay period and on the 7th day thereafter, a record shall be made of the body weight of each rat. A record shall be made of the quantity of the rachitogenic diet consumed per rat during the assay period.

VITAMIN D POTENCY OF THE MILK

In determining the vitamin D potency of the milk, the average performance of groups with respect to healing of rachitic metaphysis shall be considered, provided such average performance of a reference group shall be determined by data from rats which individually show an extent and degree of calcification equal to or greater than a condition described as positive macroscopic evidence of calcification, but less than an extent and degree of calcification described as complete healing. The data from a reference group shall be considered valid for establishing the vitamin D potency of the milk only when two-thirds or more, but not less than 7 rats, individually show macroscopic evidence of healing but not complete healing. The data from an assay group shall be considered valid for establishing that an assay milk conforms with labeled potency in terms of U.S.P. units only when two-thirds or more, but not less than 7 rats individually show macroscopic evidence of healing. The data from a rat shall be considered valid for establishing the average performance of a group only on the condition that the weight of the rat at the termination of the assay period shall equal or exceed the weight of the rat on the beginning day of the assay period, and that the rat has consumed 28 gm. or more of the rachitogenic diet during the assay period, and on the condition that the rat has consumed each prescribed dose of milk within 24 hours from the time it was fed.

The vitamin D potency of the milk is then calculated as follows:

CALCULATION OF POTENCY

The vitamin D potency of the milk may be calculated by using the following formula:

$$Y \times \frac{946}{X} = \text{U.S.P. units per qt.}$$

Y = U.S.P. units of vitamin D (total dose) necessary to produce a narrow line of calcification in the reference groups.

946 is the c.c. in 1 qt.

X is the c.c. of milk (total dose) necessary to produce in the assay group an equal or greater degree of calcification than that produced in the reference group.

Part I

Suggested Standards

IN brief review, the present Committee on Ventilation and Atmospheric Pollution was appointed in 1931 at the 60th Annual Meeting of the Association, Montreal, and finally reached a unanimous agreement on so-called "Working Standards" which were adopted by the Section on Industrial Hygiene at the 64th Annual Meeting, Milwaukee, 1935 (Year Book 1935-1936, page 74). With very slight changes these standards have been similarly adopted, as reported in the subsequent Year Books.

The committee resubmitted its report of the two previous years (Year Book 1936-1937, page 82 and 1937-1938, page 81) at the Kansas City Meeting, October 25, 1938. Only one slight change was made—for Item 14, "Ultra-violet or actinic ray effects on air or occupied space to be disregarded for the present," the last phrase was changed to read, "deferred for later consideration."

A movement to have these general standards adopted by the Governing Council of the Association after endorsement by the Committee on Research and Standards was held in abeyance, after due discussion at the Kansas City Meeting, to await further developments in the field, particularly in regard to more exact specifications.

It will be noted that, with the exception of Item 9, none of the 15 numbered items are specific in nature,

but are of general character and have been advisedly so drafted in view of the rather wide range of physiological adjustments and thresholds available to the normal individual, within which the committee felt it was not desirable to lay down closer specifications at this time.* In fact, Item 9 opened the way for controversy at the Governing Council meeting in Kansas City.

These standards are devised for the maintenance of comfort, health, and efficiency, assuming altitudes not exceeding 10,000 feet above sea level, and are to apply to *any and all* atmospheric or space environments intended for human occupancy by reasonably normal individuals.

Air and space intended for human occupancy shall possess the following qualities and conditions:

1. Cool rather than hot †—but avoiding a sense of chilliness.
2. Dry rather than damp. ‡
3. Still ‡ or moving depending upon physical activity. ‡
4. Some diversity in temperature—time and space—rather than uniformity and monotony. ‡
5. Foot level as warm as head level.
6. Radiant, *i.e.*, local heat source as an item in heating, preferred.
7. Shockless temperature differentials between air-conditioned quarters and outer air, depending upon the length of stay indoors, *i.e.*, less differential for brief stays.
8. Essentially noiseless conditioning apparatus.
9. Minimum of 25 sq. ft. and 200 cu. ft. per person, otherwise air displacement equivalent

lent to 1,200 cu. ft. per hour per person.

10. Reduction of obnoxious dusts, bacteria, fumes, vapors, and gases to their sub-danger thresholds.

11. Satisfactory primary sense impression upon entering the room or space.

12. Maintenance of comfortable conditions during occupancy (room comfort impression).

13. Sufficient replacement of "foul air" with "fresh air" to meet odor-comfort requirements. Entrainment or filtering out of objectionable industrial odors.

14. Ultra-violet or actinic ray effects on air or occupied space to be deferred for later consideration.

15. Intelligent supervision.

The items of compressed or rarefied air are not considered here.

The Committee desires to call attention to *Report No. 76* of the Medical Research Council (Industrial Health Research Board), London, 1936, 109 pp., entitled, "The Warmth Factor in Comfort at Work. A

Physiological Study of Heating and Ventilation," by T. Bedford. (Note especially "Equivalent Conditions of Warmth"—discussion of Scale with Chart—pp. 50-56 of this *Report*.)

Comments and criticisms are invited and may be addressed to the chairman or any member of the committee.

* Agreements as to the majority of the exact specifications, of interest to engineers, and correlation with A.S.H.V.E. standards were summarized in the report of this Committee (*Year Book*, A.P.H.A., 1934-1935, pp. 108-112).

† Adapted from the British Health of Munition Workers' Committee, Memorandum No. 9, 1916.

‡ "Still" implies air motion under 25 ft. per minute.

Part II

Standard Methods for the Examination of the Air

THE organization of this committee was described in the *Year Book* of 1935-1936, page 75, and the same membership of seven persons has obtained to the present time.

Some changes, however, have been made, from year to year, in the membership of the four sub-committees. These changes, chiefly additions of personnel, may be seen by referring to the annual *Year Books*.

The subtended reports for sub-committees I to IV were presented, discussed, and referred back, at the Kansas City Meeting, to the general

committee chairman for final format.

As heretofore, comments and suggestions are invited and may be taken up with any member of the committee or sub-committees as befits the subject matter.

I. Report of Sub-Committee on Physical Procedures in Air Analysis*

Instruments and Methods for Recording Thermal Factors Affecting Human Comfort

1. Air Temperature: Mercury or alcohol thermometers, preferably with silvered bulbs, capable of recording temperature within 0.5° F.

2. Humidity: Sling psychrometer.

3. Air movement: Silvered kata thermometer,^{1, 2} heated thermometer anemometer,³ or hot-wire anemometer.⁴

4. Radiation: Radiation thermopile,^{5, 6} or globe thermometer.⁷

PHYSICAL AND PHYSIOLOGICAL BASES OF COMFORT

Comfort, in so far as heat or cold is concerned, is associated with a normal heat balance between heat production and heat loss, at normal body temperature, and with no sensation of effort on the part of the heat-regulating mechanism. Four of the basic factors affecting thermal comfort are: air temperature, radiation, air movement, and humidity. No one of these is independent of the others, but their effects are quite different under conditions of minimal or maximal perspiration.

In men at rest under ordinary air conditions, the metabolic rate remains approximately constant, but the proportion of heat loss by radiation, convection, and evaporation may vary greatly, depending upon the environmental conditions, and upon individual constitutional factors. In still air at 70° , radia-

tion and convection ordinarily account for about 75 per cent of the total heat loss, and evaporation for 25 per cent. Muscular exercise may alter these values.

Loss of heat by radiation depends on the temperature of the surrounding surfaces (walls, ceiling, floor, furniture, etc.) and is independent of air temperature. The latter directly affects heat loss by convection from the body surfaces, and, indirectly, evaporation loss. Air movement increases convection loss and may reduce the radiation loss by lowering the body-surface temperature.

Insensible perspiration is regulated according to requirements for heat balance and remains substantially unaffected by humidity. Cutaneous insensible loss is now known to take place by diffusion of water through the capillaries and involves no sweat-gland activity. Cutaneous loss is also influenced by changes in the water lost from the respiratory passages, as shown by Kuno⁸ and others. When the inspired air is dry, there appears to be a compensatory decrease of cutaneous perspiration, and when the air is moist, cutaneous perspiration increases, so as to maintain the total water loss approximately constant, according to requirements for heat regulation at any given temperature.

There is a critical temperature between 75° and 90° F. (depending on

* PUBLISHED NOV. 15, 1935.

individual constitutional factors, amount of clothing, acclimatization, etc.) at which sweating breaks out. Below this critical temperature (zone of insensible perspiration) evaporation loss remains approximately constant at about 25 per cent of the metabolic rate in persons at rest, regardless of the usual variations of temperature or humidity, and the body maintains thermal equilibrium by altering its surface temperature. When physical work is performed, the critical temperature may fall below 75° , and heat loss by evaporation may be considerably increased.

Above the critical temperature of 75° to 90° F., evaporation rapidly increases according to the output of sweat that is necessary for heat regulation. Winslow and his associates⁹ have recently demonstrated that in this region of "evaporative cooling," humidity, as well as temperature, affect the rate of sweat secretion through reflex changes of blood supply to the skin, a process that is accurately adjusted to maintain heat balance at a given temperature with low or high humidity, so long as moisture can evaporate at all.

It is clear from the foregoing that under ordinary conditions, during the heating season, the rate of heat loss from the body and the degree of comfort experienced depend largely upon radiation and convection. The principal environmental factors involved are air temperature, mean surface temperature of surrounding walls and objects (or mean radiant temperature), and air movement, and the best single index of their combined effects is body surface temperature.

In warm summer weather, sensations of comfort or discomfort depend largely on the rates of sweat secretion and evaporation, as these are indicative of the effort the body must make to maintain a normal heat balance. All four environmental factors are involved, and when the external temperature ap-

proaches that of the body's surface, humidity becomes the most important factor of all.

INSTRUMENTS FOR MEASURING INDIVIDUAL THERMAL FACTORS

1. *Temperature and Humidity*

The use of air thermometers and sling psychrometers is too well known to be described here; it is important, however, that the dry-bulb thermometer be silvered or suitably screened from radiation when measuring the true air temperature.

2. *Air Movement*

Instruments for measuring air movement in rooms generally depend in principle upon the rate of cooling of heated bodies, which varies approximately with the square root of velocity. The principal ones are the kata thermometer,^{1,2} the heated thermometer anemometer,³ and several types of "hot-wire" anemometers.⁴

The *dry kata thermometer* is the simplest of all low-speed anemometers now in use. It is well suited for measuring velocities between 30 and 400 f.p.m. in air currents that do not depart greatly from a horizontal direction. In ascending or descending currents that obtain in rooms ventilated by "upward," or "downward" supply systems, kata readings are not entirely reliable, as shown by Vernon,¹⁰ owing to natural convectional currents created by the heated kata bulb, which modify the true air movement. Errors due to convectional currents may be reduced somewhat, by turning the kata to a horizontal position after the spirit has left the expansion reservoir.

Standard katas are also subject to radiation errors if the temperature of surrounding walls and objects differs much from air temperature. By the use of silvered katas, this error may be reduced to within 4 per cent of the

velocity.² When measurements are made in temperatures near 90° F., or above, it is more convenient to use a high-temperature kata (blue kata) because the standard kata takes too long to cool over its range, 100–95° F.

*The heated thermometer anemometer*³ consists of an ordinary glass thermometer having a small bulb, with an electric heating coil wound around the bulb. Small dry cells furnish the heating current, and the voltage is regulated by a rheostat according to the velocity to be measured and sensitivity desired. Readings to be taken are the temperature of the heated and an unheated thermometer, and the voltage used. The velocity is read off a table, or chart, or computed from an equation. By varying the voltage, any velocity can be measured from 10 to 6,000 f.p.m.

Owing to its small bulb size and small temperature difference between air and bulb surface temperature (10 to 15° F. for measuring room air currents), the instrument is not appreciably affected by convectional currents of its own when held in a horizontal position. By painting the bulb with aluminum paint, or by covering it with tin foil, errors due to radiation from hot surfaces are reduced to 1.5 per cent of the velocity or less. The chief disadvantage is the necessity of a source of electricity.

The hot-wire anemometer,⁴ in its simplest form, consists of a short length of platinum wire which is heated electrically to a suitable temperature, usually between 200 and 300° F. when measuring room air currents. The hot wire forms one arm of a Wheatstone bridge, and the resistances of the other three arms are adjusted so that when the bridge is in balance, the resistance and, therefore, the temperature of the heated wire is at the desired value. Changes of air movement over the heated wire change the temperature of the wire and throw the bridge out of balance. The heating current must be

readjusted in order to restore the wire temperature to its former value, and the change in current is a measure of air movement.

As a laboratory instrument, the hot-wire anemometer gives excellent results, and by the use of three wires in a pyramidal grouping, it is possible to determine current direction as well. The chief disadvantage is the elaborate apparatus it requires, and this has hitherto limited its use.

3. Radiation

The ordinary thermometer is not sufficiently affected by radiation and little if any by air movement. A room may feel too cool at 75° or too warm at 65°, depending upon the temperature of surrounding surfaces or objects. Various types of radiometers are available, but the most suitable laboratory apparatus for measuring surface temperature, or amount of heat radiated, is a sensitive radiation thermopile used in conjunction with a suitable galvanometer or potentiometer. In the field, such instruments are not convenient because they are too delicate, as well as expensive, and a great number of readings are required to integrate radiation from all directions.

Bedford and Warner⁷ have found that readings of an unheated globe thermometer (consisting of a 6" blackened copper sphere with an air thermometer at the center) may be utilized for estimating mean radiant temperature or mean radiation intensity from its surroundings when the air temperature and air movement are determined simultaneously. The mean radiant temperature (t_w) may be computed approximately from a simple equation derived by these workers:

$$t_w = t_r + 0.169 \sqrt{V} (t_r - t_a)$$

and the mean radiation intensity from the surroundings is given by:

$$1.72 \times 10^{-9} T_w^4 \text{ B.t.u./sq.ft./hr.}$$

t_w = mean radiant temperature ° F.

$$T_w = 460 + t_w$$

t_g = globe temperature ° F.

t_a = air temperature ° F.

V = air velocity in f.p.m.

The mean radiant temperature, as estimated from the globe thermometer readings was found to be within $1\frac{1}{2}^\circ$ F. of radiation thermopile readings when the difference between air temperature and temperature of surroundings did not exceed 10° F.

Radiation in rooms heated by convection methods—Under ordinary living and working conditions in this country, the extent of radiation encountered is not great, except under unusual conditions. In an unpublished study, Yaglou found that in ordinary frame or masonry dwelling, office, and school buildings, heated to 69° – 75° F. by hot water, steam, or warm air, the mean radiant temperature was never more than 2.5° F. below or above air temperature. These readings were made at points 3 ft. above the floor in the center of rooms having one to three exposures. The outside temperature during the observations was between 6° and 35° F.

Observations made 6" from a large single-glass window on a cloudy day showed a maximum cooling effect equivalent to 4° F. approximately on a windy day when the outdoor temperature was 21° F. On another day, under approximately identical conditions, but with the sun shining through the glass, the maximum solar heating effect was equivalent to about 34° F. An ordinary glass thermometer under the same conditions showed a temperature only 9° above the true air temperature.

Vernon¹¹ reported a similar experience in British factories and homes. His globe thermometer readings were seldom more than 1.5° F. above or below air temperature, except in front of coal fires or furnaces which increased

the readings as much as 75° F. above air temperature.

COMPOSITE INDICES OF WARMTH AND COMFORT

Various physical instruments have been devised to combine into a single index two or more of the four thermal factors affecting warmth, and some success has been attained within the zone of insensible perspiration when the air movement was low. Among these devices are the Eupatheoscope,¹² the resultant thermometer,¹³ the thermointegrator,^{14, 15} the unheated,⁷ and heated¹⁶ globe thermometer, and others. Valuable as these instruments may be in integrating radiation from surrounding surfaces, their indications cannot be taken as a true index of warmth or comfort, since it is difficult or impossible for any physical instrument to anticipate human response to environmental conditions.

This committee is entirely in accord with conclusions recently reached by the Housing Commission of the League of Nations¹⁷ that in all research and experimental work the four constituent thermal factors (air temperature, humidity, air movement, and radiation) should be recorded separately, whether special integrating instruments are used or not. Such readings can generally be translated into the terms of any special instrument, or special scale, combining two or more environmental factors into a single index, such as "effective temperature,"¹⁸ "equivalent temperature,"¹⁹ or "operative temperature."²⁰ A brief description of physical instruments and thermal indices now in use will be found in a recent report of the Committee on Air Conditioning of the American Medical Association.²¹

DESIRABLE AIR CONDITIONS

The test for adequate air conditions should be the comfort of the individual, his psychological and physiological re-

actions to the conditions, and last, but not least, his inclination for work. No single comfort standard can be fixed to meet every purpose. The requirements differ according to the state of health, sex, age, clothing, activity, climate, season, and degree of acquired adaptation.

For persons at rest or in light sedentary occupations, an air temperature between 68° and 73° with a moderate or natural humidity, and with an air movement under 40 f.p.m. will prove satisfactory to the majority of healthy persons, during the heating season, provided that air and wall temperatures do not differ much. When this difference is great, some physical instrument must be used for estimating the mean radiant temperature in order to arrive at the proper air temperature for comfort.

Under conditions of sensible perspiration, as during warm summer weather, desirable air conditions are difficult to establish owing to the liability of chilling during sojourn to a cooled space, when the skin and clothes are wet from perspiration. For continuous stay in a cooled space, when little regard need be paid to prevailing outside temperature, the summer comfort zone of the A.S.H.V.E.²² will probably prove satisfactory to inhabitants of the northeastern section of the United States. For most practical purposes, however, this zone has more academic than practical significance, since sudden temperature changes are difficult to avoid under ordinary living and working conditions.

Current engineering practice in cooled buildings follows a sliding temperature scale, from 4° to 15° F. below the prevailing outside temperature, when the occupants remain in the cooled space 40 minutes or more.²² According to this schedule, when the prevailing outside temperature is around 80° F., the indoor temperature is adjusted to about 75° F., and when the outside

temperature is about 95° F., the indoor temperature is kept at 80° F. The relative humidity is kept between 50 per cent and 60 per cent in both instances.

Experience with this schedule has not been satisfactory and it proved quite difficult to find a substitute that would satisfy the majority of occupants. On entering a building cooled to 80° F. in 95 degree weather, all persons invariably experience a transient feeling of chilliness, which may be pleasant to some and unpleasant to others. After about an hour in the cooled space, the majority would be comfortable, a few would still shiver, and a few might feel a little too warm. On leaving the cooled space, all persons invariably experience more or less discomfort in readjusting themselves to heat; a few may become dizzy and depressed, while others who were cold may be contented at first, but they too may have difficulty in readapting themselves to heat later.

There is much to be learned about cooling in warm weather, and how the indoor conditions should be varied in relation to those out of doors. Some persons advocate dehydration of air with a temperature reduction only a few degrees below the prevailing outside temperature; others believe that the solution of the problem lies in radiant cooling methods, but there is not sufficient evidence to favor any particular method at present.

For men at work, suitable air conditions are almost impossible to establish, owing to the changing character of the requirements, particularly with respect to the type and rate of work, type of occupancy, duration of exposure, clothing, adaptation, etc. Each industrial process presents its own factors. The manufacturer should study and regulate conditions so as to bring about maximum comfort and work output.

Suitable air conditions for various kinds and rates of work have been

studied in the laboratory by Houghton, *et al.*,²³ Arnaoutow and Weller,²⁴ McConnell and Yaglou,²⁵ and in the field by Vernon,²⁶ Sayers, *et al.*,²⁷ and others.

II. Report of Sub-Committee on Chemical Procedures in Air Analysis

THIS sub-committee, which reported rather fully in preceding years, presented no report this year. In the meantime its very efficient Chairman, Warren A. Cook, found it necessary to resign because of his change of position and increasing separation from laboratory analytical procedures. At his recommendation and that of others, Dr. F. H. Goldman, another member of the committee, was appointed its new Chairman. Dr. Goldman is Chemist

of the Division of Industrial Hygiene, National Institute of Health, Washington, D. C., where his work has been long and favorably known. The remaining personnel of this sub-committee obtains as before.—E.R.H.

F. H. GOLDMAN, *Chairman*
ALLAN L. COLEMAN
HERVEY B. ELKINS
H. H. SCHRENK
CLAYTON A. SMUCKER

III. Report of Sub-Committee on Dust Procedures in Air Analysis

THIS sub-committee rested for the current year to give more time for comments and suggestions regarding its two previous annual reports—one on dust sampling and dust counting, and the other on chemical and petrographical analyses of industrial dust. The committee especially invites expression of

opinion along these or similar lines, to be considered for inclusion in subsequent reports. The committee personnel remains as for last year.

J. J. BLOOMFIELD, *Chairman*
THEODORE HATCH
CHARLES R. WILLIAMS

IV. Report of Sub-Committee on Bacteriological Procedures in Air Analysis to the Committee on Atmospheric Pollution

Measuring Sanitary Ventilation

IN the last report of our sub-committee (Year Book, 1937-38, p. 90), two questions involving analytic bacteriologic procedures were considered: (1) the application of a bacteriologic indicator of nasopharyngeal contamination in the semi-enclosed atmospheres of our habitations; and (2) methods for the estimation of the adequacy of ventilation of these semi-enclosed spaces for the removal of microorganisms discharged into these atmospheres by the occupants.

During the past year we have studied the following analyses made by the method of sanitary air analysis described in the first report of our sub-committee (Year Book, 1936-37, p. 97):

1. 2,000 air samples in the Laboratories for the Study of Air-borne Infection, University of Pennsylvania

2. 2,500 air samples collected by the WPA Air Pollution Survey of the New York Department of Health, and analyzed at the DeLamar School of Public Health, College of Physicians and Surgeons, Columbia University

3. The results of many more analyses as yet unreported (called to our attention through personal communications)

Two simple routine procedures fulfil most of the present requirements in the measurement of sanitary ventilation:

1. Determination of the number of microorganisms present at any moment in the air of an occupied space as a result of the balance between the addition of microorganisms and their elimination by sedimentation or otherwise, this equilibrium indicating the hazard of infection to those breathing the atmosphere for a given time.

2. Determination of the rate of elimination of microorganisms by air displacement, or by disinfection by any physical, chemical or biological means.

The total count on blood agar tubes, incubated at 37° C. for 24 hrs. is found to be as useful in distinguishing general pollution of indoor air as was the body temperature agar count in sanitary water analysis. A counter has been devised for the rapid estimation of the number of colonies on tubes when too numerous to count with the naked eye. The use of this counter was described in the first report of the sub-committee, but a cut is provided for those interested.

Nasopharyngeal streptococci (*Streptococcus viridans*, predominantly *Streptococcus salivarius*) indicate potential respiratory infection in breathing air as do *Esch. coli* indicate potential intestinal infection of drinking water. Isolation of alpha streptococci from sample volumes of 5 cu. ft. of air may be quantitatively compared to the isolation of *Esch. coli* from 100 c.c. of drinking water, since these volumes represent roughly similar proportions of the daily per capita consumption.

The recognition, isolation, and identification of *Streptococcus viridans* colonies on blood-agar centrifuge tubes requires experience. The small amount of blood permissible in the tubes does not permit the formation of the characteristic green color on blood agar plates, and hemolysis due to crowding of other colonies obscures the reaction. The colonies themselves are small, round, above or below pin-head size, tending toward transparency. The peculiar color and shading of the iron rust halo surrounding each colony is, however, characteristic and almost unmistakable to an experienced eye, though, in the variety of blood alterations in the tubes, easily overlooked by less experienced observers. The effect becomes more pronounced after 24 hr. incubation.

The time of fishing the colonies from the tubes onto blood agar plates for confirmation is reached by a compromise

between the increasingly characteristic appearance of the colonies, and the danger of the more delicate colonies dying if fishing is too long delayed. A satisfactory plan has been to fish and ring colonies on the second day (24 hrs. incubation at 37° C., then keep the tubes another day or two and re-examine for development of further colonies, the second 24 hrs. being either at 37° C. or at room temperature).

In ordinary air samples, these streptococci are not so numerous but that all colonies can be fished onto blood agar plates. For convenience and economy, the blood plate may be divided into 8 sectors. The appearance of the streaks on blood agar plates is familiar to those who have studied nasopharyngeal flora. Formation of the typical green color of *Streptococcus viridans* provides sufficient identification for sanitary air analysis. Sugar tests have shown *Streptococcus salivarius* or *Streptococcus mitis* (i.e., lactose fermenting) to predominate, and sub-culturing hardly seems to repay the effort. When searching for pneumococci, inulin broth provides a rapid method for choosing those strains to which the bile solubility test is to be applied.

The air centrifuge provides a convenient method of sampling quantitatively the air for mouth streptococci in conjunction with Gordon's enrichment method of identification. In this manner the air pollution by respiratory organisms can be titrated against these mouth streptococci as an indicator in the same way that the intestinal pollution of drinking water can be titrated against *Esch. coli* as an indicator in the well known fermentation test. Comparative experience between the two methods is not yet sufficient to judge the accuracy of the enrichment method, but its simplicity recommends it for further investigation. We are now engaged in studies attempting

to determine the accuracy of, and also if possible to improve Gordon's enrichment medium in the light of later knowledge of the streptococcus group.

The second procedure has been tested under a great variety of practical conditions during the year. Since the facility of transfer of an infection from an infector to an infectee constitutes a single determination between two specific points in an atmosphere, it may be desirable to repeat the determination with the infector and infectee in reversed positions so as to compensate for the prevailing air currents, and to dis-

tribute the infection uniformly by means of an electric fan. In extensive atmospheres, several locations may be tested to obtain average conditions.

Various accessory measures may be needed for a thorough analysis of ventilating conditions.

This may include determinations of temperature, relative humidity and movement of the air, and, in the use of ultra-violet light, a suitable photometric measure of light intensity.

Coördinating Committee on Standard Methods*

Laboratory Section

ON this, the fifth anniversary of our committee, we might be pardoned if we took the time to review more than the work of the past year. However, it seems sufficient to mention but two outstanding accomplishments and rest our case on them. Our plans include developments in so many directions we can with confidence let the future take care of itself; especially is this true because we know the coming year will be conspicuous for the outward and visible signs of activities which it will reveal.

At first our functions were not clearly defined, and the reasons for our very existence were called into question. We have gradually found our place. Every member of the committee has been actively at work during these 5 years, and since work always begets work, we have found our functions expanding. Starting with 5 members, we have from time to time discovered the need for additional undertakings which have made advisable the appointment of additional members to the committee. There are now 9 members.

Methods for the bacteriological examination of shellfish constitute one of the most ancient functions of the Laboratory Section. Recollection of such matters always brings back the memory of Professor F. P. Gorham and the group of brilliant students inspired by his enthusiasm who always came to the meetings with him. If he could return now, his pride in their accomplish-

ments would be equal to the gratification he felt in their development while working with him. During the past 5 years Dr. Robert Breed has held as one of the functions of his committee the inheritance of Standard Methods for the Examination of Shellfish. During the past year it has seemed to us that the importance of the problems involved in the bacteriological phases of shellfish sanitation demanded a special committee. This has been made evident especially by the fine work of Dr. C. A. Perry. The result is that during the past few months such a group has been organized with James Gibbard as its Chairman. This committee will work toward the most efficient methods for the bacteriological examination of shellfish and shellfish waters, constantly revising such methods as knowledge advances. They will work in the heartiest coöperation with other committees of the Association interested in sanitation, in particular with the Shellfish Committee of the Public Health Engineering Section. The objectives of these two committees are identical; their functions are definitely different but wholly complementary.

For some years past the Laboratory Section has maintained a Committee on Biological Products. Therefore this group has not been affiliated with the Coördinating Committee. The belief has been growing that a better opportunity would be afforded for work toward the common purposes of the Laboratory Section if all chairmen of such committees might meet together

* Report of the Chairman.

occasionally to discuss problems which often are identical. At its last meeting the Coördinating Committee recommended to the Section Council that Dr. Elliott S. Robinson, Chairman of the Committee on Biological Products, be made a member of the Coördinating Committee. This recommendation was approved by the Section Council.

Of the two outstanding accomplishments mentioned at the beginning of this report, one is the development and establishment of a more efficient and economical method for the identification of the coliform organisms in water and sewage. This fundamental technical advance is to be credited to our Water Committee, of which Dr. John F. Norton is Chairman. I am certain, however, that neither Dr. Norton nor Mr. McCrady, who has been the Referee in personal charge of the investigation, would be willing to have omitted here recognition of the fine coöperation given us by Harry Jordan, of the American Water Works Association. He has the eternal gratitude of every one of us. Among the outstanding features of this Annual Meeting is the symposium arranged for discussion of slow lactose fermenters. The work to be reported there is destined to erect another milestone of progress in water bacteriology.

The investigations made by the Milk Committee, under the Chairmanship of Dr. Robert S. Breed, have given us more thorough and more accurate methods for the enumeration of bacteria in milk. It is the belief of the Coördinating Committee that these methods which involve the use of a special culture medium should be officially recognized and recommended. Not everyone is yet in entire agreement with this decision. Scientific progress must always be bringing about such differences of opinion. Always changes in the direction of progress will be opposed by a certain proportion of those who

have been applying the older methods. In deference to such persons the procedures commonly in use during the past several years are still permitted as alternate methods. The recommendation that we gradually go over to the more accurate and more searching technic does not imply that great things were not accomplished by the older methods. We know that their application brought about revolutionary improvement in milk quality. We can scarcely hope that the new methods will do more than lift the standard a little higher and cause the results of the examinations made in different laboratories to be more nearly uniform. At this meeting Dr. Breed is presenting a final revision of his volume on *Standard Methods for Milk Analysis*. The volume will be a reliable guide to all public health laboratory workers; it is our repository of the most recent technical and practical information on the subject.

Progress toward the compilation of a manual devoted to the Biology of the Laboratory Animal is reported by Colonel R. A. Kelsner, Chairman of the committee which has that work in charge. This volume will be an exceedingly useful one to public health laboratory workers. In it they will find all the directions required for the care and selection of laboratory animals and complete information with regard to their usefulness.

The Committee on the Analysis of Frozen Desserts, of which Dr. Friend Lee Mickle is Chairman, has had a meeting recently at which reports were received indicating active work and fundamental progress.

The committee which has been most active of all, possibly, is that which concerns Diagnostic Procedures and Reagents, and of which Dr. William D. Stovall is Chairman. Several members of this committee have already completed their re-

ports, and other manuscripts are in process of final editing. It is hoped that by the end of the year the entire group will be ready for publication; soon thereafter we shall have available a volume of technical methods for the isolation and identification of the more important causative agents of communicable disease. Its value to laboratory workers can scarcely be overestimated.

It is always a temptation for the Chairman of the Coördinating Committee to tell all he knows about the work of the various committees and thus duplicate to a certain extent the reports of the committee chairmen themselves. This temptation is particularly strong in a discussion of the magnificent work done in the past year by Dr. Stovall's committee. It is only through the exercise of a strong conscious effort that I refrain from doing so.

In closing this report I must call attention again to the gratifying accomplishments of the Coördinating Committee. There has been no unnecessary lag at any point. The work at which we have aimed each year has been accomplished; we have even gone beyond such aims. We believe our Coördinating Committee has proved that as an administrative set-up it has thoroughly justified the ambition of its instigators and may be held up as an excellent example to other sections and organizations which have technical committee work to be done.

Analyzing Frozen Desserts and Ingredients*

Laboratory Section

IN the progress report¹ of this committee to the Laboratory Section last year the *raison d'être* of the committee was sketched. Attention was called to the fact that at a Joint Session of the Laboratory and Food and Nutrition Sections, held during the Sixty-Fifth Annual Meeting in New Orleans, La., in 1936, favorable action was taken on a recommendation² that a joint committee be appointed from representatives of the two sections to prepare standard methods for analyzing frozen desserts, and that this committee be placed under the supervision of and made responsible to the Coördinating Committee on Standard Methods of the Laboratory Section. Further, in the report of last year it was recorded that a chairman had been appointed by the Section Council, with the advice of the Coördinating Committee; that a committee had been selected; that, at the two committee meetings held during 1937, refereeships had been apportioned among the members representing different portions of the United States and Canada; that much attention had been given to discussion of the functions of the committee; and that the scope and policy of the committee had been defined as follows:

The Committee for the Examination of Frozen Desserts will undertake to study and recommend methods—microbiological, chemical, and physical—which are to be used by

public health laboratories for the examination of frozen desserts other than plain ice cream and products used as ingredients which are already not within the scope of other committees. It will coöperate to the fullest extent possible with existing organizations such as the Association of Official Agricultural Chemists, the American Dairy Science Association, and the International Association of Milk Sanitarians, or other organizations which are active in this field. When other methods are considered necessary, we shall request the association which has been active in the respective field to recommend a desirable procedure. If no satisfactory method is available, this committee will use its best effort to recommend a method.

During 1937–1938 the refereeships in the committee have remained unchanged although additional associate referees have been appointed by some of the referees to assist them in the development of various phases of their problems. The full personnel of the committee will be published in the *Year Book*. A proposed additional refereeship to be filled in the near future is one on Methods of Testing for and Significance of the Presence of Coliform Organisms in Frozen Desserts.

It is urged³ again in this report that the members of this Section hear and study the report³ that the representatives on the committee from the Food and Nutrition Section will make to that Section at this Annual Meeting because that report will cover in greater detail certain of the activities of the committee. Attention is again called to the report of that committee presented at the last Annual Meeting to the Food and Nutrition Section.⁴

* Report of the Joint Standard Methods Committee on Analyzing Frozen Desserts of the Laboratory and Food and Nutrition Section (presented to the Laboratory Section).

Following the presentation of our report last year a meeting of the Joint Committee was held during the 1937 Annual Meeting. During 1938 a meeting of the committee was held in New York City at which a progress report was received from each member. The minutes of that meeting make it very evident that the committee is making real progress in developing methods for analyzing both frozen desserts and the ingredients they may on occasion contain. It has not seemed wise to rush forward so hastily that methods can be included as supplements to the Seventh Edition of *Standard Methods for the Examination of Dairy Products*, soon due to appear. Progress reports of some of the referees and associate referees are being mimeographed for distribution to as many interested persons as can be found who will review and criticise them.

Dr. F. W. Fabian, Referee for the Microbiological Examination of Ingredients, has reported that all but one of the associate referees for the microbiological examination of ingredients have placed manuscripts in his hands and he is engaged in the task of editing these reports to place them in the form of methods for circulation among any interested persons. Action by the committee has been taken so that no methods for analyzing frozen desserts or ingredients will be brought forth as official publications of the committee until approved by the Coördinating Committee on Standard Methods and by the Laboratory and Food and Nutrition Sections and until they can be released through the usual Association channels.

M. E. Parker, Referee on Sediment Testing of Frozen Desserts, in collaboration with his associate referees, has presented a report setting up in outline form the methods that have so far been studied. These cover proposed methods for sediment testing of frozen desserts,

as well as for dry milk, condensed milk, evaporated milk, and other ingredients. This referee has been asked to define for the committee, with the assistance of his associate referees, what shall constitute sediment in frozen desserts. Mr. Parker is endeavoring to work harmoniously with the referees for the sediment testing of milk and butter on the Committee for the Examination of Dairy and Food Products, and with the chairman of that committee, to the end that the procedures from this committee may be as uniform as possible with those proposed for determination of sediment in milk and in other dairy products.

Dr. J. H. Shrader, as Referee for Chemical Methods for Frozen Desserts, has been actively contacting the chairmen of committees of the Association of Official Agricultural Chemists to obtain coöperative action on several chemical methods for examining dairy products. He has reported that it seems likely that referees and associate referees may be appointed to act jointly for both associations. Dr. Shrader is asking persons working in that field to collaborate with him in the special technic involved in the application of chemical methods for colors and for saccharin in ice cream.

Dr. A. H. Robertson, as referee on that phase of our activity, has presented in practically finished form a manuscript on the Microbiological Examination of Frozen Desserts exclusive of plain vanilla ice cream, and is collaborating with Dr. Fabian, in the latter's capacity as Referee for Bacteriological Examination of Ice Cream on the Standard Methods Committee for the Examination of Dairy and Food Products, in an attempt to make the microbiological procedures for the examination of plain ice cream and those for other frozen desserts as uniform as possible.

James Gibbard, Referee for Methods

for the Examination of Gelatins and Stabilizers, in collaboration with his associate referees, has submitted proposed standard methods for the examination of those products. These methods are in so finished a form that doubtless they can soon be placed before interested persons within and outside of the Association for criticism and review.

It will be seen from this progress report that your committee is slowly emerging from the stage of closeted study into a phase of activity that may be participated in by any member of the two parent sections or by interested persons. Criticisms and comment are earnestly sought for and will be welcomed by the referees and associate referees. If furnished to the chairman of the committee, any suggestions will be placed before the committee for consideration by the appropriate referee. It is requested that the committee be continued, if such be the pleasure of the Section, for it is planned and expected that further progress can be made during the year. The hope is here expressed by your committee that in the not too distant future an edition of the *Standard Methods for the Examination of Dairy and Food Products* published by the Association

will contain supplements covering in a rather complete way the microbiological, the chemical and the physical examination of frozen desserts, ice cream mixes, and the ingredients used in the manufacture of the many frozen products that are now on the market. That accomplishment will demand the continued full coöperation of all interested persons in this and in other associations.

Examination of Dairy Products*

Laboratory Section

DURING the past year the Dairy Products Committee has continued its study on suggested formulae for standard agar. This work has been carried out under the supervision of C. A. Abele, *Referee*, with the co-operation of a half dozen or more public health laboratories. A preliminary report on his findings has been presented to the committee and is published in this Year Book.

The chairman of the committee, during the past year, attended the Western Branch A.P.H.A. Convention in Portland, Ore., in order to present in person the recent investigational work carried out under the supervision of the committee. This has resulted in unanimous support for recommendations regarding changes in the present standard procedure which are being made at this meeting.

The manuscript of the seventh edition of *Standard Methods for the Examination of Dairy Products* is now in final form and is being presented for approval at this meeting. The new edition should be available soon after

the beginning of 1939. A list of the most important changes has been drawn up for immediate publication in the *American Journal of Public Health*.† Laboratory directors are requested to coöperate in every way possible in bringing about acceptance of the recommendations and requirements made in this new manuscript. Each step forward has been taken after careful consideration and with the full realization of the fact that we have not yet completely accomplished the purpose for which the committee was originally appointed in 1905. It had been found by experience at that time that counts from duplicate samples of milk sent to different laboratories did not agree as well as was felt desirable. Even to this day, this remains a real problem in milk control work so that every effort made to bring about better uniformity in procedure is useful.

Comparative Tests of Agar Media for Standard Milk Work*

Laboratory Section

YOUR referee is at this time presenting only a preliminary report of a study of the results obtained by plating samples of milk on several media under test, and at incubation temperatures of 37°C. and 32°C. Numbers of such studies have been conducted, and the results reported in the literature. However, in order to have a basis for official action the committee was of necessity required to conduct its own study.

Plate counts of milk being subject to so many factors which materially affect the results, the initial objective of your referee was the establishment, in all laboratories participating in the study, of a procedure in full conformity with that prescribed in Standard Methods—as published in the Sixth Edition, and in manuscript for the Seventh Edition. Accordingly, with the aid of Drs. Robert S. Breed and A. H. Robertson, of the committee, an Outline of Procedure was prepared.

In the spring of 1938 an invitation to participate in the committee's study, in the manner set forth in this Outline of Procedure, was sent to the directors of 41 public health and university laboratories, and a number of laboratories were subsequently approached by Dr. Breed, making a total of 48 invitations. Ten directors agreed to

participate. To these report forms were forwarded, and the Difco Laboratories and the Baltimore Biological Laboratory furnished prepared media sufficient for the number of sample examinations promised.

Prior to October 18, 1938, reports on 244 series of sample results had been received from 6 laboratories, and have been considered in the compilation of this preliminary report. Names of the laboratories, their directors, and the participating assistants, are given later in this report.

It early became evident that results given in every report must be carefully checked, and that some definite rules must be adopted in arriving at the counts to be reported and used in this study. Because of the fact that the Outline of Procedure to be followed prescribed duplicate sets of plates of each of two dilutions, Standard Methods is not quite clear as to the procedure to be used in arriving at the count to be reported when the results of the duplicate platings do not correspond exactly. It was also quite clear that extreme caution must be exercised in accepting and including in the data counts which had been derived from overgrown or under-developed plates, and from sets of duplicate plates the results of which did not correspond with a reasonable degree of closeness. Consequently, your referee arbitrarily adopted the following rules of procedure:

* Preliminary Report of the Referee to the Committee on Standard Methods for the Examination of Dairy Products.

1. Counts based only upon obviously overgrown plates are not to be considered.

2. Counts derived only from plates having less than 20 colonies are not to be considered.

3. The ratio of the calculated counts from the two plates of any set (1:100 and 1:1,000, or 1:1,000 and 1:10,000) of the duplicate platings must be less than 1:2.5, for the final count to be considered.

4. The variation in the calculated counts from the two duplicate sets of plates must be within the limit of a deviation of 25 per cent from the mean, for the final count to be considered.

The application of these rules resulted in the discarding of a considerable number of the counts reported. Your referee must also accept the responsibility for having altered numbers of the counts reported, both to correct arithmetical errors and to make them conform to methods of reporting prescribed in Standard Methods. All counts on which this study is based have been calculated only to two significant digits.

Your referee has conceived the object of this study to be a search for trends in plate counts, when samples of milk are plated and incubated under closely controlled conditions, as prescribed in Standard Methods. Therefore, every report has been checked for media pH, media pouring temperatures, and incubation temperatures. Conformity to the criteria fixed for these conditions has been very gratifying.

This study pertains to trends in plate counts obtained by the use of 3 media—Standard Nutrient Agar, Trypton-Glucose-Extract-Milk Agar, and the agar prescribed by the American Association of Medical Milk Commissions—and incubation of the plates, as before stated, at both 37°C. and at 32°C. Each report, therefore, presents 6 distinct, but related, results. Since numerical tabulations do not necessarily produce either a clear or an accurate impression of the relationships they are intended to present, except by laborious analysis, your referee

has dispensed with tables in this preliminary report, and is presenting to the committee for consideration now the results of the platings on each medium, and of incubation at each temperature, in comparison with the results from the same samples when plated on Standard Nutrient Agar, and incubated at 37°C., in graphic form. (Note: These graphs or charts will appear in a formal final report to be published at some subsequent date.) Since this is a preliminary report, and because these charts have been too recently completed to have allowed time for analysis and comparison with published results of similar studies, no attempt to make comparisons or to draw parallels is now made.

Advantage is taken of this occasion, however, to point out that the striking variations in counts obtained under the several conditions under study are somewhat disconcerting to one interested particularly in the plate count as a criterion or factor in the grading of milk supplies from a public health standpoint.

The average lay milk control official probably ascribes to plate counts of milk on Standard Nutrient Agar, at 37°C., a greater degree of uniformity, stability, or fixity than the facts justify. In the charts presented the accuracy and fixity of counts on Standard Nutrient Agar, at 37°C., is taken for granted as a point of departure for determining the deviation of counts determined by means of other media, and a lower incubation temperature. Were another measure of bacterial content taken as a point of departure—such as the microscopic count or the methylene blue reduction time—these same counts on Standard Agar would probably also appear to be variable and misleading. But, custom and usage has made the plate count on Standard Agar, at 37°C., the basis for such bacterial count limits for milk supplies as have

AGAR MEDIA

been fixed, and these counts must, therefore, be used as the basis for comparisons made in this study. It is rather disconcerting, therefore, to note that samples yielding counts of an identical magnitude on Standard Agar, at 37°C., may yield counts of 3, 4, or even more magnitudes under several of the other cultural conditions studied. This denotes complete unpredictability in the relationships of counts made with a new medium and at a lower incubation temperature (particularly the latter), and presages great difficulty in fixing bacterial count standards and limits for milk, ice cream, and other dairy products.

However, this report presents preliminary data only. Your referee does not now express an opinion about the desirability of prescribing changes in medium and incubation temperature in Standard Methods, leaving that to be determined, after discussion, by the members of the committee.

The laboratories which have thus far participated in this study are:

Division of Bacteriology, New York State Experiment Station (Cornell University), Geneva, N. Y. Dr. G. J. Hucker, Chief in Research, William Walters, Bacteriologist.
City Health Department, St. Louis, Mo. Dr. Joseph C. Willett, Chief of Laboratories, J. Lazarov, Bacteriologist.

Bureau of Health, Portland, Ore. Dr. Leigh H. Churchill, City Bacteriologist, Wilfrid C. Kennell, City Chemist.

Bacteriological and Serological Laboratories, Department of Health, Louisville, Ky. Dr. James A. Kennedy, Director, W. L. Williams, Sanitary Bacteriologist.

Ontario Department of Health Branch Laboratory, Ottawa, Ont. Dr. Frank S. Letts, Director, J. Baron, Asst. Bacteriologist.

New York State Department of Health, Bureau of Milk Sanitation, Mobile Laboratory. W. D. Tiedeman, Chief, N. J. Hohl, Bacteriologist.

(NOTE. After this preliminary report had been presented, a number of reports were received from the Bureau of Laboratories, Detroit Department of Health, Detroit, Mich. Dr. Joseph A. Kasper, Director, Gail A. Smith, Laboratory Medical Aid.)

The committee is deeply indebted to all of those named for the time, use of equipment, and directional effort devoted to these multiple examinations of milk samples, without which this study would have been impossible. And it is also indebted to Dr. H. G. Dunham, of the Difco Laboratories, Detroit, and to R. J. Carski, of the Baltimore Biological Laboratory, Baltimore, for supplying the participating laboratories with Standard and T-G-E-M Agars, and with A.A.M.M.C. Agar, respectively, without charge.

C. A. ABELE, *Referee.*

Industrial Sanitation*

Public Health Engineering Section

IN addition to work done by engineers specializing in industrial hygiene, there remains a broad field of work for public health engineers in industrial sanitation. Both the specialized work and the work in industrial sanitation done by the general engineer continue to grow in scope and amount.

The latter is handicapped by a grave difficulty of collecting and keeping up to date files of the voluminous and necessary working data which are amassing on the subject. The engineer promoting and applying practical methods to the field of industrial sanitation encounters one certain difficulty in a degree worse than in most specialties. His source material must be culled from many specialties, he must follow the contributions of the physician, the chemist, the sanitary engineer, the safety engineer, the heating and ventilating engineer, the electrical engineer or physicist, and the bacteriologist in their respective groups of publications.

The Committee on Industrial Sanitation has undertaken to study these sources of material with a view to reporting progress on what means should prove practicable for expediting the assembly of the most valuable part of such working material for the public health engineer. The motive underlying this activity is advancement of the application of industrial sanitation.

The committee has also given consideration to the part the engineer

should play in the development and administration of programs. For three consecutive years verbal reports have been made by the chairman at annual meetings to interest members of the Public Health Engineering Section in extending the work of the engineer in this field.

Specific recommendations on desirable policy have not been formulated for this report because the committee has not yet reached unanimity of opinion on the proper scope and direction of industrial sanitation or the best relation of the public health engineer to it.

However, a joint session on industrial sanitation between the Public Health Engineering and the Industrial Hygiene Sections has been secured for the 1939 annual meeting at which time opportunity should be available to clarify many problems which have arisen because of the overlapping of jurisdictions or interests of the two sections in many phases of industrial sanitation.

The committee sponsored a questionnaire to ascertain the desires of some 75 non-medical industrial hygiene technologists in the matter of adequacy of existing organizations for meeting their needs when it was learned that a new national organization of these workers was being formed. The situation was placed before the Executive Board of this Association in Kansas City from whom assurance was received that every reasonable effort would be made

* *Proceedings, P. H. E. S.*

within the flexibility of the Association's framework to retain the interest and affiliation of this group. The problem still confronts the two sections mentioned inasmuch as the leadership in the technology of industrial sanitation now enjoyed by this Association

is threatened if this group cannot be induced to forego complete deflection.

CHARLES LUNDY POOL, *Chairman*

ALEXANDER ZIMMERMAN

Qualifications for and Training of Milk Sanitarians*

Public Health Engineering Section

THERE is a definite tendency on the part of health administrators to fix by statute, regulation, or otherwise, qualifications for milk sanitarians or inspectors. This year your committee has undertaken a study of these qualifications in the various states as well as the educational facilities available throughout the country for both the general and special training of milk sanitarians.

So-called "dairy and milk inspectors" who came and went with every change in local administration regardless of education, fitness, or experience, are almost a thing of the past. Today, however, there are many milk inspectors or sanitarians, particularly in local municipal employ, who have had little if any opportunity to study the technical side of milk sanitation.

We recognize that the protection of public health through sanitation of our milk supplies requires technical knowledge in the light of which some health department efforts of former days, based only upon the principles of good housekeeping, look foolish. The spectacle of uneducated and untrained men literally "straining at gnats and swallowing camels" in the name of milk sanitation is evidence enough of the need for fixing qualifications and providing means for the men already in and

entering this field to meet those qualifications.

As an indication of what health officials expect of milk inspectors we quote the following from a paper¹ by Dr. John L. Rice, Commissioner of Health of New York City:

The inspector has to be enough of an architect to give advice on the construction and layout of a milk plant, and enough of a mechanical engineer to pass judgment on the sanitary construction and proper operation of milk equipment. He should be enough of an expert on water supply and sewage disposal, at least to have sufficient ability to detect irregularities, and understand the operation and sanitary precautions for the relatively simple water or sewage plants. He must to some extent be a bacteriologist and chemist in order to make microscopic counts and simple field tests and interpret the results, and to understand laboratory reports of analyses. He should be a psychologist and educator of sufficient ability to sell himself and his milk control program to producers and dealers of milk. He must have poise, alertness, and at times a knowledge of court procedure in the event that court action becomes necessary.

For the sake of brevity the term "milk sanitarian" as used here includes both the positions bearing the title of milk sanitarian and milk inspector.

Our information has been obtained by correspondence with state departments of agriculture, state health departments, and universities. In practically all states either civil service requirements or department regulations fix qualifications for *state* milk sanitarians. While it may be desirable

* Report of the Joint Committee on Milk Supply of the Conference of State Sanitary Engineers and the Public Health Engineering Section, A.P.H.A.

both to set and raise standards and provide special courses for state personnel, the major problem at present has to do with local or municipal employees.

All 48 states have reported. Six states, namely, California, New Jersey, New Mexico, New York, Washington, and West Virginia, have either statutes or regulations fixing qualifications for municipal milk sanitarians. These differ widely.

California law requires that city or county inspection services be "approved" by the State Director of Agriculture, who in turn fixes qualifications for inspectors by formal regulations.

Under the laws of New Jersey, the State Department of Health is authorized to and does give qualifying examinations to local health officers and sanitary inspectors, including milk inspectors. The law further provides that licenses, in three classes, be issued to those approved by the State Department of Health as a result of these examinations.

In New Mexico, regulations of the State Board of Public Welfare require that county and district sanitarians be certified as sanitarians by the State Bureau of Public Health, and further include qualifications as to education and experience and require a written examination by the Bureau of Public Health.

The public health law in New York State authorizes the Public Health Council to prescribe by regulation the qualifications of dairy and milk inspectors paid from public funds. Under this authorization, regulations have been incorporated in the State Sanitary Code fixing qualifications as to education and experience for milk inspectors in three grades and specifying the grade of inspector required to be in charge of milk sanitation in municipalities in various population groups.

The statute in the State of Wash-

ington requires that milk inspectors "shall be graduates of a recognized dairy school or shall have completed a course in dairying in a college where such instruction is given."

In West Virginia, regulations of the State Public Health Council set certain age and educational requirements, and in addition require special training, including 6 weeks at the West Virginia Public Health Training Center or its equivalent.

The methods used in California, New Jersey, New Mexico, New York, and West Virginia are flexible enough so that standards can be raised at will by the authorities. The Washington statute so fixes the requirements that another act of the legislature is necessary to change them.

Some milk sanitarians now in service are inclined to view with fear the fixing of qualifications. When new qualifications are established consideration is generally given and rightfully so to the men in service who are willing to improve themselves by taking special training. Qualifications should serve to curb the tendency to change milk sanitarians with every change in administration, giving the municipality better service and giving the sanitarians a greater sense of security. Qualifications covering experience should not be placed so high that there is no place in the system for men with adequate training to get started.

Recognizing the demand for trained milk sanitarians, some colleges offering public health work are strengthening general undergraduate courses having a bearing on milk sanitation. Others are offering, either on their own initiative or in coöperation with state health departments and conferences of mayors, special short courses for either postgraduates or for practical milk sanitarians with limited education. These short courses vary considerably in duration, frequency, and composi-

tion. Three day courses with programs comparable to those offered at the annual meetings of some of the larger associations or with milk inspectors have been offered at the University of Missouri, Ohio State University, Texas A. & M. College, and Texas Technological College.

Another opportunity for the milk sanitarians to obtain special training has been offered by the U. S. Public Health Service in the form of 1 week seminars.

We have not attempted to circularize state associations of dairy and milk inspectors. It is known, however, that associations in California, Connecticut, Massachusetts, Michigan, New York, Oklahoma, Pennsylvania, Texas, and West Virginia in addition to the International Association of Milk Sanitarians carry on active meetings with programs designed to keep members informed on current developments in the field of milk sanitation.

Special short courses of instruction in milk sanitation have been offered by a few colleges. These are open to milk sanitarians as *in* service training. Cornell University in New York State offered a 15 day course for the first time this year and the Pennsylvania State College offers a course of similar length yearly.

There is a tendency on the part of some to discount these special courses and to insist that broad general education is essential. For new men entering the field, there is no doubt that broad general training in public health, particularly in public health engineering, constitutes an important background. For the men already employed, general education through regular courses is impractical, and some form of special education is important if progress is expected. Otherwise we must sit back and wait for relatively young untrained men with tenure now in service to grow old and die before we can expect to secure

necessary improvements. Such courses also offer an opportunity to men with broad educations but little experience to get practical detailed information in a short time. It appears that there is need for these short courses as well as for broad training in regular undergraduate college courses.

Eleven colleges including Yale, Connecticut State College, Massachusetts State College, Massachusetts Institute of Technology, University of Michigan, Michigan State College, University of Minnesota, Cornell University, University of North Carolina, Texas Technological College, and West Virginia University are reported as offering courses which include material of special public health value to milk sanitarians in varying degrees. Courses in dairy management, animal husbandry, milk products judging and dairy manufacturing, such as are offered in most agricultural colleges, have not been considered because of the general lack of public health emphasis in such courses.

SUMMARY

The need for better trained men is recognized in the field of milk sanitation as in many other fields. Six of the 48 states prescribe qualifications for local milk inspectors by statute or official regulation. Eleven colleges in 8 states are offering fundamental courses in regular undergraduate work that are of special value in training milk sanitarians from the standpoint of public health. Two colleges in different states are offering special 15 day courses of instruction for milk sanitarians. The U. S. Public Health Service offers 1 week seminars. State departments of health, colleges, conferences of mayors, and milk inspectors' associations in 10 states and the International Association of Milk Sanitarians have technical meetings or conferences annually which are usually of 3 days' duration. Increasing opportunities for both under-

graduate and *in* service training in milk sanitation should make it possible for milk sanitarians to meet higher educational requirements.

The committee does *not* propose that this association adopt qualifications for milk sanitarians. Although it is too early for the committee to recommend definite qualifications, for consideration by state officials, the goal is suggested that all new appointees should at least be graduates in sanitary engineering, dairying, veterinary medicine, or some other field allied to milk sanitation, and

that either as graduates or undergraduates they should have attended the equivalent of one short course or seminar in the more specialized public health aspects of milk control.

Engineering Service in City Departments of Health*

Public Health Engineering Section

IN 1919 less than half of the 48 states had engineering sections in the state departments of health. But, within the decade following, all but four or five of the least populated states had public health engineering divisions, and since then there has taken place a steady, progressive enlargement of engineering organizations in the state health departments. The advance in this type of state work has continued with increasing momentum up to the present day. Before this movement began in 1919, the situation, in the majority of the states of this country, was such that haphazard, ill-planned water and sewage works would be installed by cities and towns; uncontrolled pollution of streams was common; and there was little state direction or supervision of major environmental health problems relating to water supply, sewage, milk, foods, mosquitoes, etc. There were of course, some notable exceptions to this general picture, particularly in the few commonwealths where state health engineering supervision was given an important place.

This brief account of the transition period in state public health engineering work is here presented in the belief that it will help make understandable the present status of public health engineering services in the municipalities. The initial move toward this widespread advance in engineering services of the

states did not in general come from the individual state health officer. It got its impetus from many sources, such as the surveys of state health work conducted by the U. S. Public Health Service, the focusing of publicity on calamitous results where this supervision was lacking, the organization in 1920 of the Conference of State Sanitary Engineers, the repeated presentations of the need for this supervision at the annual conferences of the State and Territorial Health Officers, and, finally, the offer of funds and technical assistance by the U. S. Public Health Service and the Rockefeller Foundation, for inaugurating such work in the states.

The situation today in city public health engineering divisions does not approach the level that had been reached by the states for this work by the year 1919. It is, on the whole, comparable to the 1895-1905 period when the first few engineering divisions in state health work were being established. Professor Charles Gilman Hyde¹ reports as a result of his study and collection of data, that he found in 1934 "there are probably not more than 30 public health engineers employed in 24 city health departments in 13 states." At the same time he points out that there are 320 well organized, full-time city health departments. It is Professor Hyde's conclusion that each of the 211 cities with a population of 50,000 or over "should enjoy the benefit of the full-time services of one or more sanitary engineers in an or-

* Report of the Committee on Municipal Public Health Engineering.

ganized, properly equipped bureau." In summarizing the picture he adds, "It is only recently, and as yet in a pitifully small way, that appreciation of the value of such service has been recognized and expressed by the employment of public health engineers in the smaller units of public health administration: county, district or unit, and municipal."

It was for the purpose of finding out if there had been any marked change in this situation, that a brief questionnaire was sent out by the Municipal Public Health Engineering Committee this past summer to the state sanitary engineers, to gather information about public health engineers in municipalities. Each state engineer was asked also to give information about local unit health departments where the population was at least 60 per cent urban. Replies from 44 states were received. The data indicate that in July, 1938, there were employed in the health departments of 53 cities and urban units, 66 public health engineers. This represents an increase of more than 100 per cent, in the past 4 years, in the number of cities employing public health engineers. Most of this increase is made up from the number of municipal health engineers added to local health departments in the 4 states: Minnesota, Missouri, Ohio, and Texas. In one state, Alabama, where the local health work is entirely on a county basis, with no municipal health department, it was reported that there were 29 engineering sanitary officers in county health units. The number of engineers employed in counties with predominantly urban population in Alabama was not furnished; thus, this figure is not included in the above totals.

The present situation, in this phase of municipal health work, may be summarized by pointing first to the fact that in only one in four of the 211

cities with population of 50,000 or over, are public health engineers employed, and secondly that of the 37 largest cities with a population of 250,000 or over, only 14 have one or more public health engineers in their health departments.

The question whether or not the larger cities in this country have a need for the services of engineers in their health departments is ably discussed in the paper of Professor Hyde cited above, and also in papers by Joel I. Connolly,² and James L. Barron.³ In these reports one finds accounts of the engineering bureau's activities, which range over a very wide field—from water supply and waste disposal matters, to the problems of insects and nuisances; from control of milk, food, and air supplies, to projects in industrial hygiene, plumbing, and housing sanitation. Some health workers might question the soundness of the principle of having a health department carry on, through its engineering bureau, the supervision of all these environmental health matters, asserting, perhaps, that this work is already covered by other agencies, such as, for example, the water department, or that it could be directed by non-engineering personnel.

A discussion of some of the activities of an engineering bureau of a city health department will perhaps explain why our committee shares with Professor Hyde the belief that each of the 211 cities with a population of 50,000 or over "should enjoy the benefit of the full-time services of one or more sanitary engineers in an organized, properly equipped bureau."

In the field of water supply, the local health official has indisputably the responsibility for the safety of the public water supply, even though the planning, construction, and operation of the system is up to another department or rests with a private corporation. An experienced health officer would hesi-

tate to shift this responsibility by accepting the assurances of other departments of the city or state, without a check directly under his own supervision. He would want his department to have a collateral supervision and a continuous check on this most important source of disease. The unfortunate position in which the local health officer may find himself, as a result of the failure of his department to check conditions relating to a water supply was strikingly revealed in the investigations and hearings concerning the Croydon (England) typhoid epidemic of 1937. In addition to the regular public water supply, the local health department regulates directly many small subsidiary water supplies, such as private wells, springs, etc., which are used for domestic purposes or at food establishments. The complicated hydraulic and sanitary problem of checking the hazards to the consumers' water supply from plumbing defects in buildings, has been one of the recent jobs brought to local health departments, or, more correctly, a job that has been returned to the health department.

With respect to the disposal of wastes, the city health department has somewhat the same function as with the general water supply. The actual collection, treatment, and final disposal of sewage, garbage, and other wastes are the work of other departments, but it is the health official's task to see that the necessary health requirements are fully met in carrying out these city functions. Here again the health official will need the help of his engineer to insure that water supplies are not endangered, that beaches and other recreational areas are not polluted, or that nuisances from garbage or other wastes do not occur.

In the field of food protection, local health departments are confronted with ever widening responsibilities. The outstanding health achievement in the

thorough, exacting protection of milk, attained in various cities, has led health workers to give similar specialized attention to many other food problems, and to the methods of their preparation, *e.g.*, shellfish, baked custard products, cheese manufacturing, syrup and jelly manufacturing, restaurant sanitation, etc. That the public health engineer's part in the achievement in milk sanitation has been of major significance, is clearly evidenced by his work on the problem of correct pasteurization. His share is apt to be of like importance in the further advances in food control, and in the sanitation of food processing plants. In the very large cities where separate bureaus for food control are warranted, the direction of such work need not be limited to engineers. It may properly be held by one of the other specially trained sanitary workers.

In industrial hygiene and sanitation, the demands upon the city health department are becoming ever more pressing. The control of dust, fumes, excessive temperatures, harmful chemicals, etc., in shops and factories is largely a job for the engineer. Similarly, pollution of the general atmosphere in most large cities, from industrial operations and the burning of fuel, presents a control problem which the local health department must to a large extent take over, and for the solution of which engineering guidance is obviously a prerequisite.

The activities of the health department in mosquito control both for malaria eradication and pest elimination have largely resolved themselves into drainage and land grading operations or the manipulation of impounded waters. In other problems of pest control, such as rodent eradication, fumigation, and disinfection, the effective measures are properly formulated and supervised by the local public health engineer.

It is not believed necessary to

lengthen still further this list of local health services of an engineering nature. It should by now be obvious that in modern cities environmental health factors have reached such a large number, and are of such technical complexity and importance as to warrant an engineering service. New products, new processes, new machines and structures; new ways of working, playing, living; all ceaselessly changing and modifying every problem—require renewed investigation and continuous control of ever present hazards by health minded, technical experts, if the public health is to be safeguarded intelligently. Because of his specialized training and experience in subjugating the forces of nature for the benefit of man, the public health engineer is well qualified to carry on and direct the activities in the various phases of the environmental health field. He is, furthermore, best fitted to correlate the health influencing activities of official public works departments, the public utilities, and private industry into a coöperative, unified, efficient community environmental health program. This job is beyond the capacity of the sanitary inspector. The non-engineer health worker, finding himself on unfamiliar grounds, would be handicapped in initiating this work. But the trained public health engineer can directly stimulate vast amounts of public health work in other departments and agencies, for he can talk the language of the engineers who are the ones planning, building, and operating the basic physical works

of the city. The committee holds that the cost to a city of appointing one or more public health engineers would prove to be a sound investment.

It is also the committee's belief that the old as well as the new fields of environmental health which are best handled by engineers in municipal health departments, should be brought to the public's attention. In this education work the federal and state health engineers can play a rôle of paramount importance. They, themselves, are becoming more aware of the outstanding place the municipal health engineer occupies in the community's health protection, and they can bring this information to the citizens of their state. To make up the lack of municipal public health engineers, especially in the larger cities, is in the opinion of this committee, one of the more immediately and definitely necessary tasks to be included in any national program for better health protection.

Plumbing*

Public Health Engineering Section

THE Joint Committee on Plumbing during the past few years has devoted its studies to the health hazards involved in plumbing installations due to interconnections between drainage systems and water distribution systems in buildings. It has pointed out that there is a growing recognition of the folly of permitting contamination of drinking water in buildings through faulty plumbing installations after spending huge sums to deliver water of safe sanitary quality to the mains in the street.

The large number of investigations made during the past few years by federal, state, and municipal health authorities, and by associations of plumbers and manufacturers have produced unquestionable evidence that designs and methods of installation commonly used with many plumbing systems and fixtures have been responsible for localized pollution of water supplies in buildings. Such pollution frequently results from back drainage or back siphonage into water lines of the contents of these fixtures or the contents of a water pipe or drain into which these fixtures discharge. In most of these investigations special emphasis has been laid on hospital installations, where the maximum of care against infection is essential, but the evidence collected has general application to all plumbing installations whether in a large institution or a private residence.

So much publicity has been given to the health hazards involved in defective plumbing systems and fixtures, and as to how contamination of water supplies in buildings may occur through back siphonage caused by the creation of partial vacuums in water distribution systems, that it does not seem necessary to discuss these matters in this report.

Notwithstanding this publicity, faulty plumbing installations are still being made and potentially dangerous types of fixtures are still being manufactured. Although many plumbing inspectors are well informed, there are still some who do not know how to correct the conditions they find. Some water works officials have not as yet recognized the danger of polluting their water supplies from such interconnections, or the importance of proper pipe sizes within buildings in preventing the occurrence of a partial vacuum. There are also other very important plumbing hazards, such as, for example, leaking sewers and drains located over places where water, ice, or food are stored or handled.

In considering measures to prevent or eliminate health hazards due to defective plumbing and to comply with the requirements of plumbing codes, a distinction may properly be made between proposed new installations and existing or old installations. In new installations the maximum protection can and should be obtained, because many protective features can be embodied by the architect during design,

* Progress Report of the Joint Committee of the Conference of State Sanitary Engineers and the Public Health Engineering Section, A.P.H.A.

and the selection of individual fixtures, satisfactory types of which are available, is unrestricted so that protected types can be used. In old installations the incorporation of desirable design features is often precluded by existing structural conditions, and as the fixtures are already in place, they cannot be completely protected except by replacement. Consideration should be given also to the relative importance of various defects from a health standpoint; e.g., a submerged inlet on a wash basin is less dangerous than on a bedpan washer. Furthermore, one should not lose sight of the fact that the frequency of vacuum may vary both as between different buildings, and between different floors of the same building.

In undertaking a campaign to eliminate health hazards caused by faulty plumbing fixtures a survey of existing installations should first be made. This survey should be made by a trained personnel. When the survey has been completed, a table listing the unprotected fixtures should be prepared, and recommendations for the correction of the conditions found should be made. When making recommendations it should be borne in mind that some fixtures are interconnections at all times, others are interconnections under normal operations, while others become interconnections under certain conditions which may exist at infrequent intervals. In dealing with existing installations the worst conditions should be corrected first. A definite program should be worked out. The corrections should be made as soon as practicable and, if possible, without unduly curtailing the normal daily routine of the occupants of the building in which the protective devices are being installed.

A large amount of work has been done in the testing and development of fixtures which will prevent the pollution of water supplies by back siphonage. New developments are constantly

taking place. It is believed, however, that sufficient progress has been made so that fairly definite recommendations can be made.

The problem of preventing contamination of water through plumbing defects involves both material things such as fixtures and the more intangible human equation. Properly-designed fixtures, adequate pipe sizes, and well trained plumbers to install them, are equally necessary.

FIXTURES IN NEW BUILDINGS

In new buildings, hazards to health may be eliminated by requiring permits and the submission of plans. It is necessary to have

1. Plans covering both fixture design and piping layout and sizes, approved before building permits are issued, followed by
2. Requiring the construction and installation to be done by qualified plumbers bonded and licensed under a system requiring proof of ability to recognize and avoid dangerous connections
3. Having the job inspected by conscientious, competent plumbing inspectors, both at the time of erection and periodically thereafter
4. Identifying by distinctive colors, water piping systems conveying potable water and those carrying water which has been polluted or is subject to pollution, to prevent confusion during subsequent repairs or replacements
5. Requiring plan approval, permit and reinspection whenever changes are made in a plumbing system

Direct connections between potable water supplies and unsafe water supplies may, in general, be avoided by maintaining an unenclosed air gap of sufficient size between the point of discharge from the potable supply pipe and the highest level to which sewage or non-potable water can possibly rise. Additional measures for preventing leakage of unsafe water into a supply used for drinking purposes are the prevention of submerging of any part of a potable water supply pipe in any sewer or container holding non-potable water

and, conversely, by preventing pipes carrying impure water or sewage from passing through or over containers of safe water. This principle has been applied, for example, in dual water systems, where the potable supply is piped outside of a tank up to a point above the top of the tank, discharging above the rim, while the non-potable supply may enter the tank at the bottom, if desired.

It has been suggested that it would be practicable in new buildings to run special pipes to flush valves of toilets and to no other fixture from an elevated tank used solely to supply this piping system, with the potable water discharging into the tank at an elevation above the rim. The object is to assure that if siphonage should occur, no fixture except a toilet would be supplied by the contaminated water and, at the same time, avoid placing a protective device on every individual flush valve. In favor of such a plan there have been urged the following considerations:

1. Economy of installation
2. No moving parts to stick
3. Quietness of operation
4. No "spitting" through openings

Opposed to this plan is the fact that it is not foolproof. Changes in fixture locations may lead to connections to the most conveniently available source of water, without regard to its safety. Having two water systems, one of which is actually or potentially contaminated, invites interconnections between them. Therefore, this arrangement is not recommended by this committee.

A suitable device for flushing water-closets and assuring that siphonage from them into the water supply will not occur, is a flush tank meeting the following conditions:

1. The bottom of the flush tank higher than the rim of the water-closet
2. The tank overflow large enough to carry away readily the full flow of water through

the supply pipe to the fixture when the valve is wide open and the pressure is the maximum available.

3. The overflow drained into a suitable fixture, thereby removing possible temptation to plug the overflow

4. The discharge opening and all other openings in the water supply to the tank not less than one inch above the highest possible level of the water surface in the tank

5. No part of the water supply pipe, valves, or fittings submerged in the water within the tank

6. Free access of air into the flush tank above the water surface without passing through the water-closet

7. The tank so constructed and covered that foreign materials cannot accidentally be introduced into the tank

8. Provision made for adequately hushing the sound of the water as it fills the tank

9. The cover fastened on the tank in such a way as to require the use of tools to remove it.

Attention is invited to the fact that the customary flush tank, equipped with a hush-tube discharging below the water level, fails to meet these conditions in several respects. There does not appear to be any insuperable obstacle in supplying a flush tank which will meet the conditions named.

Manufacturers' representatives, with whom this matter has been discussed, point out that the second condition mentioned, namely, that the tank should have an overflow large enough to carry away readily the full flow of water into the tank, is possibly the most difficult to meet. That is because the trend is toward higher rates of flow into the tank to permit quicker refilling. Even old ballcocks, in many instances, when the float is held down, will admit water faster than the customary overflow will remove it, and increasing the rate of filling would necessitate still larger overflow pipes. Furthermore, such large overflows are not desired by manufacturers who wish to keep the flush tanks small, so as to compete more easily with flush valves in small toilet rooms.

FIXTURES IN EXISTING BUILDINGS

When one considers the problems of making the plumbing safe in an existing building, there is usually less latitude than in the design of a new one. Extensive revamping of the plumbing design is ordinarily prohibitive in expense. There is possible the use of flush tanks meeting the requirements already outlined. In many cases, there may be great difficulties in getting such tanks installed, because

1. The necessary space may not be available for a flush tank
2. Objections are raised against waiting for a tank to refill before it becomes possible to flush the fixture again
3. The owner feels that he has an investment in his present equipment which he is loathe to lose
4. The margin of safety afforded by such a tank over a protected flush valve is not very obvious to owners generally.

When faced with such a situation, the health official may find himself between the horns of a dilemma. If he insists upon a complete physical separation of the potable supply of water and the fixtures, the difficulty of securing the remedy may unduly delay, if not altogether prevent, his success. On the other hand, if he does not secure any improvements, he fails to protect the public health.

At such a time, one may perhaps consider the possibility of a compromise upon some less complete means of protection which gives greater promise of ready acceptance, on the theory that half a loaf is better than none. It may be expedient to permit the use of devices, which, though giving a considerable degree of confidence that siphonage will not take place, yet provide less than complete protection. There are many such devices and there will undoubtedly be others. Among them are vacuum breakers for application to the discharge side of the flush valve.

Many, if not all, such vacuum breakers draw in air to prevent siphon-

age and may not only draw air through the ports provided for the purpose, but through the water-closet as well. It is considered undesirable to obtain air from the latter source for entry into a pipe conveying potable water. Also, if the water surface in the fixture is at suitable elevations, a spray of water may be carried into the water pipe through certain vacuum breakers, by a stream of air drawn from the toilet. Therefore, the more conservative view has been that a loose disk or other similar device should be used in addition to the vacuum breaker, not with the vain hope that such a device will remain tight, but with the expectation that even though it does not usually remain tight, the effect of the device will be to reduce sufficiently the velocity of air entering through the rim openings, that no spray or particles of solid matter will be carried into the water supply pipe. Such a device also may serve as a second line of defense temporarily, pending repairs if the vacuum breaker gets out of order.

The committee believes that in existing buildings where the difficulty of securing complete protection is so great as to be out of proportion to the benefit, certain combinations of vacuum breakers with loose disks or similar devices, may, in the discretion of the health authority having jurisdiction, be permitted without approval, and with no guarantee that permission to use them will continue indefinitely.

Building owners occasionally ask a health authority to agree that, if they will put in vacuum breakers and loose disks to correct potential health hazards upon their property, the health official will never ask them to make further changes. In the present state of development of knowledge and invention in this field, any guarantees should be made by the manufacturer rather than by the health officer.

When hydraulic conditions in a

building, as determined by tests made by competent personnel, indicate that the likelihood of a partial vacuum occurring is extremely remote, and where it would be impracticable to meet all the usual requirements, health authorities may be warranted in permitting the omission of the loose disk or similar device (but not the vacuum breaker), upon the water pipe leading to non-syphon-jet types of water-closets. Syphon-jet types of toilets have constantly submerged water inlets and, therefore, in most cases, present a greater health hazard than most simple flush-rim water-closets without a syphon-jet, in which the water inlets are only occasionally submerged, as when a stoppage of the drain occurs.

The results of tests of the hydraulic conditions in any building should be presented to the health authority having jurisdiction before permission to omit the loose disks is granted.

A convenient form of loose disk for use with a flush valve equipped with a vacuum breaker is the "non-return stop." A number of combinations of such loose disks with vacuum breakers have been tested. Others no doubt will be tested from time to time.

It is the belief of competent investigators, in which this committee concurs, that in the present state of the art, a health official may permit in existing buildings, without approval or guarantee of any kind, expressed or implied, devices which are to be installed for the prevention of siphonage from fixtures through flush valves into potable water supply systems, provided these devices are designed, constructed, and installed in accordance with the general principles set forth below, and provided, further, that they are properly maintained in good condition and have passed suitable tests:

1. The bottom of the vacuum breaker shall be at least 4" above the spill line of the fixture

2. The breaker shall be of non-corrodible material and shall be so designed as to be able to prevent the formation of any partial vacuum of more than 1" of water in the flush valve tail-piece, regardless of the condition of the flush valve

3. The air valve shall be so constructed that it can be inspected or renewed with a minimum of expense and labor

4. A complete cycle of all moving parts, if any, shall be made each time the flush valve in the supply piping is opened and closed

5. Vacuum breakers shall not leak under any degree of back pressure

6. Vacuum breakers shall operate quietly and not prevent adequate flushing of the fixture

7. Little or no air shall be drawn from the fixture to break a partial vacuum, and especially at no time shall the velocity of any air drawn from the fixture be enough to permit the withdrawal of any solid particles or liquid from the fixture

There are devices on the market which, while in good repair, have fulfilled the conditions outlined above when subjected to rigid laboratory tests. It is possible, of course, that some weaknesses may develop after these devices have been in operation for a period of several years, which are not apparent at this time, or that their use with a type of water which causes increases in back pressure, through liming up of water passages, may develop difficulties. Therefore, any permission granted for their use should be revocable.

TENTATIVE SPECIFICATIONS

Following are descriptions of certain devices which appear to meet the above conditions at the present time, when used with loose disks, as previously mentioned.

A. One type of vacuum breaker for use on the outlet end of direct flushing valves is an assembly of a ring-type disk holder unit concentrically around the tube which forms the inlet end of the vacuum breaker.

The disk holder is normally in position to prevent full force of a vacuum in the water supply line from acting on the

contents of the water-closet or other fixture which the flush valve supplies. Under this condition the air-ports are fully open.

When the valve is flushed, the disk holder is pushed up by the flowing water and closes the vents, or air-ports. The disk holder drops to normal position as soon as water stops flowing. It completes a cycle of these movements each time the flush valve is operated, and does not interfere with proper flushing of the fixtures.

B. Another type of vacuum breaker has a 1" opening to the atmosphere, with air valve constructed so that it can be inspected or renewed without disturbing the flush valve or flush connections. The air valve seat is not over 1" in diameter. The air valve moves freely and clears the nearest wall by $\frac{1}{8}$ " so as to prevent sticking or wear. Vacuum breaker places no material restriction on rate of flow, and the moving parts go through the entire cycle each time the fixture is flushed.

C. Still another type is a "Venturi" vacuum breaker for use on the outlet end of direct flushing valves. In the inlet end of the vacuum breaker, it contains a non-corrodible disk, having 4 slotted openings near its outer edge, and a $\frac{1}{4}$ " diameter hole through its center.

When the valve is flushed, the water flows through the openings in the disk, into a $\frac{3}{4}$ " diameter tube and then into the fixture. This tube is surrounded by a slightly larger tube, leaving an annular opening between the tubes. When subjected to a sustained vacuum of $\frac{1}{2}$ atmosphere, a sufficient quantity of air is drawn through 2 slotted openings in the $1\frac{1}{2}$ " outer pipe, then through the annular space between the tubes, and finally into the water-supply line to prevent the water from rising more than 1" in the tail-piece of the flush valve.

The committee will add descriptions of other vacuum breakers to this list

from time to time, as sufficient additional information concerning them becomes available.

Because of the differences in back pressure in certain water-closets, several different types of vacuum breakers are made by some manufacturers. It is important that the proper type be used for the fixture which it serves.

With certain waters, liming up of the passages in a water-closet may occur, requiring a change from one type to another after a period of use, to avoid "spitting" of water through the air-ports when the fixture is being flushed. Therefore, permission to use a vacuum breaker and loose disk combination should be based not only on having it installed and maintained properly, but also upon its continued suitability to the purpose. If water spurts from the air-ports during flushing, the vacuum breaker cannot be considered suitable, because it will not be long before it occurs to someone that closing the ports will save a lot of mopping of the floor. With the ports closed, the usefulness of the device vanishes.

As an additional safeguard, a stable type of flush valve should be used in all cases, inasmuch as there is a great difference between the tendency of various types of flush valves to open under a negative head. By "stable" is meant that when the valve is in the closed position, a partial vacuum in the water supply pipe tends to seat the valve more firmly.

A water-closet of the side-spud type, wherein the water connection is below the flushing rim, is more subject to siphonage than other types. Bowls of this type should not be permitted in new installations and should be replaced when any general revamping of existing plumbing is undertaken. Special care should be used to safeguard the water supply in such cases by the use of loose disks to supplement the vacuum breakers. The submerged-inlet type of

integral spout lavatory and the bathtub with submerged inlet are other fixtures which should not be sold or installed in future. Manufacturers should cease to encourage the production and sale of side-spud toilet fixtures, and the making of these and other submerged-inlet fixtures unquestionably will cease if the public refuses to buy them.

The size of a safe air gap has been given considerable study. Inlets should be raised above the top of the fixture a distance equal to not less than twice the diameter of the water inlet. The Minnesota State Board of Health suggests the following minimum distances: lavatory, 1"; laundry tray, 1½"; bathtub, 2".¹ The University of Iowa and the Board of Health of Chicago, working independently, have also come to regard these minimum distances as adequate for the prevention of siphonage. These air gaps should be measured vertically from the elevation at which the water would overflow onto the floor, to the level of the bottom of the water inlet. "Overflows" connected to the drain are not considered in determining the air gap.

SUMMARY AND CONCLUSIONS

All plumbing fixtures should be proof against siphonage. In new buildings it is practicable through the use of definite air gaps to give 100 per cent protection against back siphonage. In existing buildings local conditions should determine the degree of protection which is feasible and practicable. These local conditions may be ascertained through inspections and tests made by

qualified personnel. Certain vacuum breakers which have been tested and found to give a high degree of protection are described. Safe air gaps for certain common types of fixtures have been determined. Only air gaps are recommended by the committee for the prevention of siphonage, but substitutes may be permitted without approval where conditions with respect to pressure in the pipes and type of fixtures installed warrant their use.

Action should be taken by appropriate state authorities to prevent "dumping" of unsafe fixtures barred from cities upon small villages and rural communities.

Water superintendents should cooperate with the health authorities in preventing future sources of water contamination from plumbing, and in locating and eliminating existing ones.

The plumbing industry should help by refusing to manufacture, sell, advertise, or install unsafe fixtures and devices.

The public health workers should seek to educate the public on the need for safe plumbing, encourage further studies, and promote more adequate and effective plumbing inspection.

Shellfish

Public Health Engineering Section

IT was decided the committee's report this year should cover procedures recommended to be followed in determining areas from which shellfish may be marketed directly.

The following report, therefore, is based on the papers and discussion presented at this meeting and on subsequent correspondence with those attending.

FACTORS TO BE CONSIDERED IN DETERMINING AREAS FROM WHICH SHELLFISH MAY BE MARKETING DIRECTLY

Decision with reference to approving areas from which shellfish may be marketed directly should be based on information obtained by technically qualified competent persons, making a careful detailed sanitary survey of the area. This decision should be based upon information obtainable both by physical survey and by bacteriological examination of overlying waters. The water examinations may be supplemented by bacteriological examinations of the shellfish themselves, but wherever the results so obtained are inconsistent with the results of water examinations, the conclusions based on the water examinations should prevail.

The areas from which it is finally decided shellfish may be marketed directly should be separated from the unapproved or contaminated area by a zone or band of water from which shellfish may not be marketed, without first subjecting them to an approved cleansing procedure.

THE SANITARY SURVEY

Adequate maps or charts of the area and of the adjacent shorelines are necessary. U. S. Coast and Geodetic Survey charts are usually admirably

suited for this purpose. On the maps or charts should be shown water depths over the shellfish producing areas, and the location of the natural and the planted areas. All properties ashore, particularly houses and sources of pollution close enough to the water's edge to be significant, should be shown. The locations of public and private sewer outlets, privies, etc., should be plotted. The average quantities of sewage discharged and the degree of treatment it has received should be recorded. The stations at which water and shellfish samples are being collected should be shown.

The principal sources of pollution are usually (1) cities, towns, or small communities discharging sewage and trade wastes, (2) houses situated along the shore, and (3) shipping.

The effects of the contamination from resort places upon shellfish areas should be studied. Summer residents in the vicinity of oyster growing areas are not so much a threat to the safety of the oysters as are residents occupying properties during the active shellfish season. Summer colonies near clam flats may, however, be sources of serious contamination.

Current studies should be made, and the course of floats released near important sewer outlets at several stages of the tide should be plotted when such information is significant.

The probable dilution of contamination with clean sea water should be considered. So also should recentness of contamination. Pollution probably originating from human sources should be considered to be much more serious than that from animals or from cultivated fields or from marshland, etc.

BACTERIOLOGICAL EXAMINATIONS

Bacteriological examinations of water or of shellfish should preferably be made during the actual shellfish season. Since there is a difference between the summer and winter concentration of coliform organisms in some areas where shellfish are taken the year round, the decision should be based upon conditions prevailing when the sanitary risk is greatest. Bottom samples, if taken from very deep water, probably portray with greater exactness and fidelity the actual condition of the water surrounding the shellfish at the time of sampling than surface samples. In ordinary shellfish growing areas, however, wave action and currents may bring about an interchange of bottom water for top water, and vice versa, so that over a period of time there may be little or no difference between top and bottom samples. In practically all instances coming to the attention of the committee this has been found to be the case, even for deep waters. In view of the fact that the top samples can be collected more cheaply and rapidly, and in view of the fact that sewage being fresh water, flows over the salt water rather than under it, top water samples from a practical standpoint are in most instances to be preferred to bottom samples, in that the most highly contaminated portion of the overlying waters is apt to be

sampled. The top water sample should be collected in a sterile bottle, either while held in the hand or secured to the end of a stick in such a manner that with a circular stroke the bottle is plunged to a depth of a foot or two beneath the surface.

A large number of reasonably accurate samples at a given station or in a given area collected at all stages of the tide, are to be preferred to only a few samples more meticulously collected and more precisely and more accurately determined. Adequate care, however, should always be exercised both in collecting and examining samples.

Water samples should be examined bacteriologically according to *Standard Methods of Water Analysis*, current edition, American Public Health Association. One or more tubes in each of three dilutions; namely, 10 c.c., 1 c.c., and 0.1 c.c., should be examined for each sample. In special studies where oyster and overlying water samples are to be compared, five tubes in each of three dilutions may be examined. The results should be recorded as most probable numbers per 100 c.c. of sample. There is no objection to examining more than five tubes in each dilution if laboratory facilities permit. Generally speaking, it is hardly advisable to examine more. For shellfish samples 1 c.c., 0.1 c.c., and 0.01 c.c. dilutions may be employed advantageously. Tables for the numerical interpretation of fermentation tubes results, in terms of most probable number of coliform organism per 100 c.c. of sample, may be made up following McCrady's suggestions as outlined in *Public Health Journal* (Canada), May, 1918, or *Reprint 1621, Public Health Reports*, March 23, 1935.

When water samples are being collected, the date, location, and depth at which the sample is taken should be recorded; the temperature and density of the water in the area should be de-

terminated from a sufficient number of observations, but need not be taken for all samples unless they are spaced far enough apart to make it necessary to do so; the stage of the tide should be stated. This can conveniently be recorded as the number of hours since low water at some controlling point in or near the area. The direction and velocity of the wind at time of sampling should also be noted. Tide predictions for any area can be obtained from the tide tables published by the U. S. Coast and Geodetic Survey, Washington, D. C., or can be obtained from that agency by correspondence. The average bacteriological density at high water and at low water can be reported in most probable numbers per 100 c.c. of samples.

Stations may be established on the chart by the intersection of vertical and horizontal lines drawn at some convenient interval apart as 1,000 ft., 500 ft., etc., the sample being credited to the intersection to which it is nearest. By giving the vertical lines numbers and the horizontal lines letters, each intersection or station can be designated by a letter and a number; for example, 7 A, 10 G, 9 AA, 17 GG, etc.

Sampling stations can also be determined by two sextant angles taken simultaneously between objects on shore whose positions are plotted on the chart. This degree of precision is, however, seldom warranted in taking water samples, but may be at times justified when oyster samples are collected, or may be used to plot positions of the sample collecting boat whenever the course is changed if more convenient determinations of its position cannot be made.

INTERPRETATION OF RESULTS

When an area obviously subjected to more or less direct contamination of human origin as ascertained by float and current observations is thus

studied, restriction lines can be drawn as soon as decision is made regarding the degree of contamination deemed to be sufficient to warrant condemnation. For a number of years regulatory authorities in the United States have assumed that where the contamination shown by the bacteriological samples was probably of human origin and more than 50 per cent of the 1 c.c. portions were positive, they were warranted in prohibiting the taking of shellfish directly from such areas for market purposes. This has been shown¹ to be equivalent to a most probable number of about 150 coliform organisms per 100 c.c. of sample. Where the pollution is definitely not of human origin, a standard of cleanliness established by esthetical considerations which public opinion will support should be set.

Experience with this standard seems to indicate that it is apparently sufficiently rigid to protect shellfish consumers from disease, provided reasonable sanitary precautions are taken by those engaged in gathering the shellfish. In most of the instances in which shellfish have been blamed for the spread of disease, the shellfish became contaminated while being held for market after having been gathered, and were eaten raw on the half shell. There seems to be, however, at least one instance² in which shellfish were taken from waters meeting the standards above set and yet having become responsible for an outbreak of disease, because they were gathered from relatively shallow waters by a typhoid carrier who may not have taken the precautions he should have taken while over the oyster beds.

Unpublished reports seem to indicate that an outbreak may have occurred recently in another state in a similar manner.

These two instances may point to the need for passing all shellfish for the half-shell trade through a cleansing

process after they are gathered unless carriers can be rigidly excluded from the shellfish industry. Sanitary control of shellfish products would then be placed on a plane comparable to that recommended for the production of milk, in that all areas from which shellfish are marketed would first have to attain a minimum standard of cleanliness after which the shellfish taken from there for the half-shell trade would have to be passed through a cleansing or conditioning or storage process in a sense comparable to pasteurization in milk production. While your committee does not believe that the time is at hand when such a rigid standard could be enforced throughout the whole industry, the desirability of striving for such a goal should be pointed out, particularly in the production of shellfish for consumption on the half shell.

Possibly if shellfish growers who take these precautions were permitted to market their product under a preferential branding or labeling, such as "Grade A Cleansed," or "Grade A Conditioned," the day when oysters could be marketed on the half shell only after having been grown in clean areas and cleansed or conditioned in approved plants, would be hastened.

ZONE BETWEEN CLEAN AND CONDEMNED AREAS

This zone has not always been clearly defined in the past. We stated above that when more than half of the 1 c.c. portions of the water samples were positive, corresponding to a most probable number of 150, the taking of oysters for market directly from such areas should be prohibited unless subjected to some approved cleansing procedure. This locates the off-shore boundary for the zone. The in-shore boundary of moderately contaminated areas from which shellfish may be taken for cleansing in shellfish cleansing

plants has been set in some jurisdictions by the line on which 50 per cent of the 0.1 c.c. portions of the water sample are positive. This is, of course, an arbitrary line. Experience over a period of several years seems to indicate that it is safe for soft clams, and this line might be considered as forming the in-shore boundary of the zone.

Soft clams found inside the above line have been considered as being too badly contaminated to be suitable for cleansing in shellfish cleansing plants. It is believed the same standards may be applied to oysters.

CONCLUSIONS

Additional experience is needed before one can say with certainty that the standards above suggested will always result in producing shellfish entirely safe for consumption. It is believed that a conservative course to follow has been laid out above, and that it can only be modified with safety after sufficient further experience.

Those desiring to liberalize these standards should remember that the best interests of the shellfish consumer must always be borne in mind by the shellfish producer if his business is to be placed on a permanently successful basis, and should not ask the consumer to take chances. Even though it cannot be proved that the use of shellfish from sewage contaminated areas causes sickness, such taking is esthetically objectionable.

With respect to waters from which shellfish intended for the half-shell trade—and therefore always eaten raw—may be taken, your committee is of the opinion, in view of the difficulties encountered in enforcing sanitary regulations to be observed by those engaged in gathering and marketing such shellfish, that before they can be considered to be free of all possibility of spreading disease, they will have to be gathered from clean areas as outlined above, and

then be passed immediately prior to shipment through a properly operated state supervised and licensed, cleansing or conditioning plant.

In bringing about this improvement, your committee is also of the opinion that permitting such packers or shippers to label or brand their product with a label, brand, or tag issued by the state and protected against imitation, would hasten the universal adoption of this procedure without at first actually making it mandatory. The committee should keep in close touch with the results being obtained at shellfish cleansing plants, both in this country and abroad.

The grading of shellfish products, similarly to the grading of milk and milk products, may be a subject worthy of future study and report by your committee.

NOTE: The committee desires to express its appreciation of the helpful criticisms received from Sol Pincus, Deputy Commissioner, New York City Health Department; H. N. Old, District Engineer, U. S. Public Health Service, New Orleans, La.; Warren J. Scott,

State Sanitary Engineer, Connecticut Department of Health; Walter J. Shea, Chief, Division of Purification of Waters, Rhode Island Department of Public Health; A. P. Miller, District Engineer, U. S. Public Health Service, New York, N. Y.; James Gibbard, Department of Pensions and National Health, Ottawa, Canada; C. A. Perry, Director of Laboratories, Maryland State Health Department; Dr. G. H. Coombs, Director, Maine Department of Health and Welfare; and others who took part in the discussion and correspondence leading to the preparation of this report.

House Trailers and Trailer Camp Sanitation*

Public Health Engineering Section

HOUSE trailers and the many problems created by their widespread use continue to be of interest to public health officials and many others.

The public health principles involved in the control of house trailers and trailer camps are basically the same as those encountered in the sanitation of tourist camps having cabins and camping facilities and were discussed in the committee's 1937 report.¹ These factors pertain to sewage and waste disposal, water supplies, milk and food supplies, control of contact infections, and the control of insect-borne diseases. The opportunities for the pollution of water supplies by the promiscuous dumping or discharge of sewage and wastes from house trailers have been obvious. The necessity for safe water and milk supplies for house trailer occupants is apparent also. Proper spacing may be of great assistance in controlling the spread of certain communicable diseases as well as controlling the spread of fires. Persons traveling from areas in which malaria or other insect-borne disease are epidemic or endemic might readily disseminate infection in far distant areas, and, similarly, people from areas free of certain insect-borne diseases might easily contract such diseases in regions that constitute reservoirs of infection.

To the end that the factors outlined above may be brought under reason-

able control, many public health officials have expressed a desire for a set of uniform, recommended regulations. It is the purpose of this report to present rules and regulations for consideration which your committee believes will suffice for the purposes outlined.

TREND IN HOUSE TRAILER USE

It is difficult to obtain reliable statistics pertaining to trends in house trailer use. Business depression undoubtedly affects all forms of travel, including house trailers. Some observers report a decrease in tourist travel in years just preceding events like the Chicago world's fair in 1933-1934 and the scheduled world's fairs in New York City and San Francisco in 1939. Weather certainly exerts some general influence on travel.

From observations in the far west and in Yellowstone National Park,[†] it seems that tourist travel of all sorts as well as travel via house trailer decreased in the western part of the country in 1938 as compared to 1937. Of the motorists who entered Yellowstone in 1936, 1.23 per cent towed house trailers; in 1937, 1.76 per cent; and in 1938, 1.5 per cent. In this group 10 per cent of the house trailers were being used as permanent living quarters in 1937, whereas in 1938 an increase to 12 per cent was noted. Florida reports an increase in house trailer use in 1938 over 1937.

In the far western states, two com-

*Report of the Joint Committee on Summer Camps and Recreable Places of the Conference of State Sanitary Engineers and the Public Health Engineering Section, A.P.H.A.

[†] See Appendix.

mittee members observed during the summer of 1938 an average of about one house trailer for each 50 miles of travel on main highways, not including units parked in roadside camps. In Florida this many have been observed during the "off" season in the summer months, while in winter many more are seen.

NATIONAL INTEREST IN PROBLEMS

Many organizations have concerned themselves with the house trailer, its use, and the new problems which its use has created. Included in this group are the American Municipal Association² and the Council of State Governments,³ both of whom printed reports in 1937. Other organizations such as the Conference of State and Provincial Health Authorities of North America, the National Safety Council, The American Association of Motor Vehicle Administrators, the Society of Automotive Engineers, the American Camping Association, and the National Association of Master Plumbers, as well as state and multi-state camp owners associations have taken active interest in developments. Papers were presented at both the Western Branch and Southern Branch, A.P.H.A. annual conventions by members of this committee.

The California Camp Owners Association and the National Association of Master Plumbers have gone on record as favoring the installation in house trailers of standard plumbing equipment provided with traps and vents and having standard couplings for connections to sewers.

SPECIFICATIONS FOR HOUSE TRAILER CONSTRUCTION

Although it would be nearly impossible to regulate the construction of all house trailers, the larger manufacturers might be induced to follow reasonable, uniform specifications for the installation of water tanks, toilets, sinks, waste

tanks, and drainage outlets in accordance with recommendations of the American Public Health Association and the Conference of State Sanitary Engineers.

It has been suggested by some persons connected with the manufacture of house trailers that facilities be installed at gasoline service stations for the purpose of emptying house trailer tanks containing sewage and other water-carried wastes. The further proposal has been made that such stations provide parking space for house trailers on the basis that camp operators are not warranted in making the expenditures necessary for house trailer accommodations on the basis of probable return on their investment. Such a plan is predicated upon the service station operator being able, by reason of probable sales of gasoline and similar products, to obtain more business from house trailer occupants stopping on his premises.

Your committee fails to see how or why gasoline service station operators could afford to install satisfactory sanitary facilities and make a smaller charge than camp operators. Special facilities are needed for house trailers and trailerites should be willing to pay a reasonable charge for the service provided.

There is lack of agreement among health authorities as to whether or not the use of chemical or septic tanks on house trailers should be permitted at all. Certainly no such units should be equipped with overflows or flushing valves which might discharge on to the highway or ground. The most objectionable feature about septic or chemical tanks is the ease with which they may be dumped. Neither specifications nor standards for tank construction are included in this report because it is believed that their installation should not be encouraged until better protective devices are available. Most states

regulating trailer camps do not permit the use of toilets in trailers while parked in camps but expect house trailer occupants to use camp facilities. The extreme difficulty in completely enforcing such a regulation may be readily appreciated, especially in so far as the use of chemical toilets is concerned.

The following construction specifications are suggested:

HOUSE TRAILER SPECIFICATIONS

1. *Water Storage Tanks*

a. *Removable Tanks*

(1) Openings, filling, and pouring spouts shall be protected from contamination by adequate covers.

b. *Stationary Tanks*

(1) Overlapping caps shall be provided for the protection of the lips of filling pipes and spouts.

(2) Tanks and filling connections shall be located so as to preclude contamination by leakage, spillage, or discharge of liquid wastes.

2. *Sewage and Waste Disposal*

a. *Toilets*

(1) Whenever water flush toilets are provided they shall be installed in compliance with a plumbing code acceptable to the state department and the soil pipe from the toilet shall have a fitting which will allow for its easy connection to a sewer system and which will be leakproof when not so connected.

(2) Chemical toilets shall be constructed of substantial, corrosion resisting material. Instructions regarding correct chemicals, quantity required, and means of disposal of toilet contents, shall be permanently posted in toilet compartment by manufacturer.*

(3) Dry toilets are not recommended.

b. *Sinks, Refrigerator Drains, etc.*

(1) All waste lines from sinks and similar fixtures shall be properly trapped and vented and discharged through one outlet which may easily be connected to a sewer system.

3. *Screens*

(1) All windows, doors, and ventilators shall be fitted with 16 mesh corrosion resisting screen.

4. *Stoves and Heaters*

(1) All stoves and heaters shall be installed and vented in a manner which reduces fire and carbon monoxide hazards to a minimum.

TRAILER CAMP RULES AND REGULATIONS

After considerable study, the committee presents herewith, a set of rules and regulations which may be used by either municipalities or states or both for the uniform regulations of house trailer camps. In areas in which no statutory authority exists for the enforcement of such rules and regulations, they may nevertheless be incorporated as a part of recommended public health procedure. Owners of trailer camps complying with established standards should be given recognition in some way which will assist the travelling public to choose a camp on the basis of health safeguards provided.

RECOMMENDED TRAILER CAMP RULES AND REGULATIONS

Section 1. Definitions

(a) A trailer camp is herein defined as any tract or parcel of land, maintained, offered, or used for the parking or camping of house trailers, house cars, or similar portable units of habitation.

(b) A house trailer is herein defined as any house car, house trailer, trailer home or similar mobile unit which may be used for semi-permanent or temporary living quarters.

Section 2. Supervision

(a) Every trailer camp shall have at least one competent attendant or caretaker whose duty it shall be to maintain the camp, its facilities, and equipment in a clean, orderly, and sanitary condition. He shall also keep a record of all house trailers parked in the camp under his supervision including the name and address of the owner, the license numbers, and state of origin of cars and house trailers, and the number of occupants of each unit.

*The policy of some states is against the use of any trailer camp on highways or in camps.

Section 3. Location and Space

(a) No trailer camp shall be so located that the drainage of the camp area will endanger any water supply. All camps shall be well drained and located in areas free from ponds, swamps, and similar places in which mosquitoes may breed.

(b) Each car and house trailer shall together be allotted a space of not less than 700 sq. ft. Each unit shall abut or face on a driveway or clear unoccupied space of not less than 20 ft. in width, which space shall have unobstructed access to a public street or alley. There shall be a space of at least 10 ft. between every house trailer and any other house trailer, building, or other structure.

Section 4. Water Supplies

(a) An adequate supply of safe water under pressure shall be provided in all parts of every trailer camp. At least one water supply outlet shall be provided for every two house trailer units and in no case shall a house trailer site be more than 100 ft. from a water supply outlet.

(b) Special hoses shall be kept for the filling of water tanks on house trailers and shall be stored off of the ground under sanitary conditions when not in use. These hoses shall be used for no other purpose than the watering of house trailers, and shall be so handled and used that they may not cause contamination of water either in house trailer tanks or in the water supply system.

(c) The dipping of water from open springs, wells, streams, or lakes for water supply purposes is prohibited.

Section 5. Toilet, Bathing and Laundry Facilities

(a) All plumbing in trailer camps shall comply with the state plumbing code, the rules and regulations of the state department of health, and with any or all local ordinances pertaining to plumbing and the disposal of sewage and other water carried wastes.

(b) Water flush toilet facilities shall be provided in conveniently located, well constructed buildings having good, natural, and artificial lighting, adequate ventilation, and floors of concrete or similar impervious material. Concrete curbs extending at least 6" above the floor shall be provided, and the floor sloped to adequate drains. The interior walls and ceilings of such buildings shall

be of smooth material painted with a light colored paint.

(c) Separate toilet facilities marked by appropriate signs shall be provided for males and females, at least one for each 15 persons or fraction thereof. At least one urinal shall be provided in each toilet building for males. (d) Toilet buildings shall be located so as to be within 200 ft. of all house trailer camping spaces.

(e) One lavatory shall be provided for every three toilets or toilets and urinals.

(f) Separate showers with hot and cold water shall be provided for both males and females, and the buildings containing them shall comply with the requirements of Section 5, item b. One shower head shall be provided for each 20 house trailers or fraction thereof. Wooden or cloth mats, grids, boards, or walkways are prohibited.

(g) All floors in shower and toilet rooms shall be disinfected daily by the use of chlorine compounds or other materials in strengths approved by the state department of health.

(h) A laundry room or building constructed as specified in Section 5, item b, shall be provided with laundry trays and hot and cold running water.

Section 6. Slop Sinks

(a) Slop sinks properly trapped and vented shall be provided in convenient locations, at least one within 200 ft. of each house trailer camping space. All slop sinks shall be equipped with water faucets which shall be protected from back-siphonage. Slop sinks shall be so constructed and installed that they may be used for the cleaning of both cans and slop jars.

Section 7. Disposal of Sewage and Other Water Carried Wastes

(a) All sewage and other water carried wastes shall be disposed of into a municipal sewer system wherever possible. In camps in which city sewer connections are not available, disposal shall be into a private system which includes a sanitary means of disposal, the operation of which creates neither a nuisance nor a menace to health and which is approved by the state department of health.

(b) A sewer connection shall be made available at each house trailer camping site for connection to the combined liquid

waste outlet of the trailer. The type of connection used shall conform to all state and municipal plumbing code requirements and the rules and regulations of the state department of health.

(c) No water flush toilets may be used in trailers unless connected to the sewerage system in accordance with state and municipal plumbing code requirements and the rules and regulations of the state department of health.

(d) Facilities shall be provided at each house trailer camp for draining the contents of chemical toilets and sewage storage tanks into the sewer system. Such facilities shall have concrete or equally impervious floors and shall be adequately screened against flies and other insects. The management shall provide for the thorough cleaning of these facilities at least once daily and oftener whenever necessary to maintain them in a clean, sanitary condition.

(e) Wastes from sinks and refrigerators may be discharged into covered, metal receptacles and disposed of into slop sinks without being discharged on the surface of the ground, provided specific approval is obtained from the state department of health.

Section 8. Garbage and Refuse Collection and Disposal

(a) Fly tight metal containers shall be provided for the deposition of garbage and refuse, at least one for every two trailers; one for each trailer is recommended. At least one depository shall be located within 100 ft. of each trailer camping site.

(b) Garbage cans shall be emptied at least once every 2 days and shall not be allowed to become foul smelling or breeding places for flies.

(c) Garbage and refuse shall be disposed of in a manner approved by the state department of health.

Section 9. Cleanliness of Premises and Fire Protection

(a) All camping areas shall be kept free of litter, rubbish, and inflammable material at all times. Hoses and portable fire extinguishers shall be available and in good repair for use in fighting fires. The fires shall be made only in stoves, incinerators or other equipment intended for that purpose.

Section 10. Electrical Outlets

(a) Electrical outlets for each trailer camping site shall be provided and installed in compliance with all state and local electric wiring codes and ordinances.

Section 11. Miscellaneous Laws and Regulations

(a) In addition to the requirements set forth in these regulations, all house trailer camps and facilities shall be established and constructed in compliance with all existing state and local statutes, ordinances, codes, and regulations.

Section 12. Communicable Diseases

(a) It shall be the duty of all house trailer camp managers to report immediately to the local health officer all known or suspected cases of communicable diseases.

CONCLUSIONS

While the use of house trailers has created some new problems in public health control, fundamentally they are all related to known and tried procedures. Some persons have been unduly alarmed over the house trailer. Dr. Guy S. Millberry, Dean of the College of Dentistry of the University of California, reports⁴ that he travelled 20,000 miles in 42 states and 3 provinces of Canada during 1937 and 1938 without observing any flagrant violation of sanitary precautions by trailerites. He makes the pertinent observation that it is difficult if not nearly impossible to expect to obtain sanitary accommodations in trailer camps much better than those which exist generally in the area in which the camp may be located.

Experience in various states seems to indicate that trailer camps may best be supervised or regulated by existing laws and rules and regulations pertaining to tourist camps. In some instances certain amendments or additions to existing statutes and regulations may be needed. The regulations set forth in this report should be

adequate in most cities and states in so far as they pertain to public health.

Recent Development in Waterways Pollution Control*

Public Health Engineering Section

UNDER the impetus of increasing public interest in waterways pollution abatement, many important events have been taking place. Recent years have brought forth a number of outstanding developments that clearly show certain trends in pollution control. Administrative practices have been undergoing analysis, and legislative needs emphasized. Concepts of how best to cope with interstate or major drainage basin pollution problems have been undergoing revision, as evidenced by the present trend away from informal pollution control agreements toward definite compacts between states, backed by state legislation and Congressional approval. Accordingly, in the preparation of this report of your Committee on Waterways Pollution, it was decided that a brief review of some of the more important developments would be timely and stimulate further interest in pollution control measures. References are given to pertinent publicized material. Grateful acknowledgment is also made of data and information obtained from correspondence, unpublished reports and memoranda which were made available to the committee.

EARLY LEGISLATION

In the United States, early legislation looking toward correcting pollution conditions was enacted in Massa-

chusetts. In 1872 the first important investigation was authorized, and this was carried out by the State Board of Health. The precedent established would appear to have influenced legislation in other states, as many subsequent laws for pollution control have designated boards of health to be the administrative agencies. In addition, conservation or game and fish departments, and public service commissions, and other state agencies have been called upon to carry out certain phases of pollution control legislation.

In 1893 Congress authorized¹ the U. S. Public Health Service to cooperate with state and municipal boards of health in the execution and enforcement of the rules and regulations of such boards; and further, in 1912² authorized studies and investigations either directly or indirectly of navigable streams and lakes of the country. The Public Health Service has accordingly extended assistance to states in making pollution surveys, in carrying out water, sewage, and trade waste treatment studies, and in conducting other important activities from the pollution control point of view.

The trend in legislation appears to be away from the inflexible prohibitory type, such as the Oil Pollution Act passed by Congress in 1924, and toward the regulatory type with policy fixing boards or commissions. The Sanitary Water Boards of Pennsylvania and Illinois, the Michigan Stream Control

* From Report of the Committee on Waterways Pollution.

Commission, and the State Committee on Water Pollution of Wisconsin are examples of state bodies created by law to control pollution.

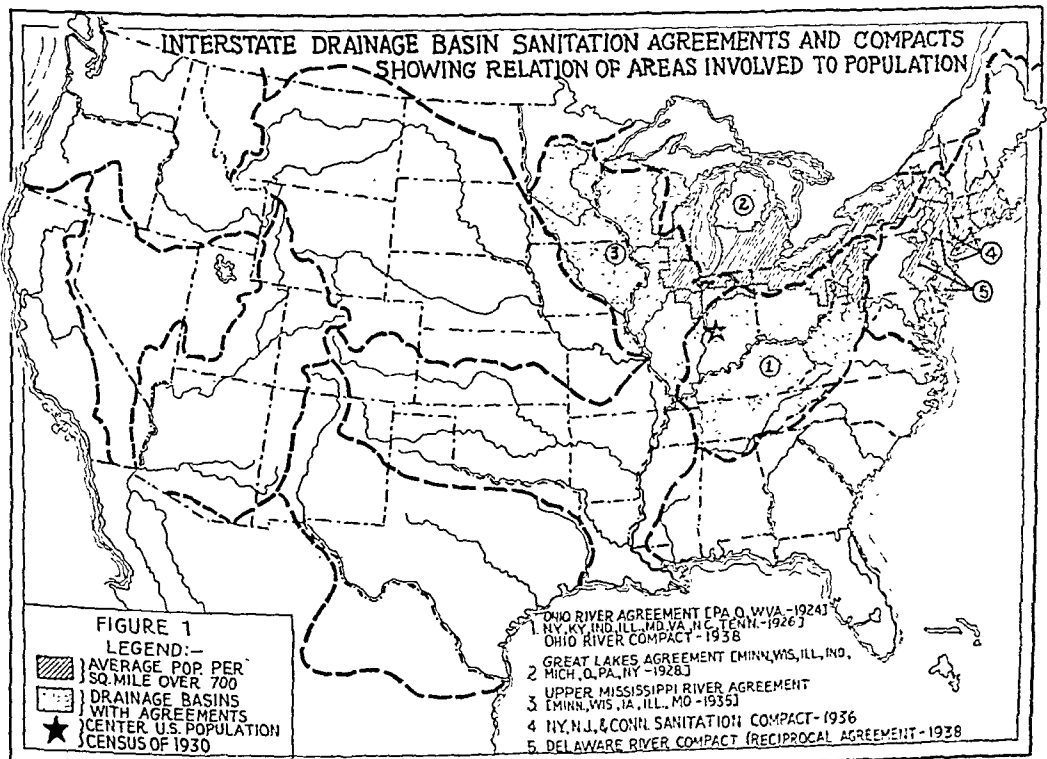

PROGRESS MADE

Creation of these regulatory bodies has aided materially in the development of plans and procedures for curtailing pollution that best fit local needs. Activities of this nature have been more pronounced, as might be expected, in those states where population is the greatest (see Figure I), and major industrial growth has taken place. The progress made has been slow until the advent of federal aid through emergency relief measures passed by Congress in 1933 and subsequently. Many municipal sewage treatment works have been installed under the impetus of federal grants. The progress in reducing industrial waste pollution has been retarded to some extent by technical and economic considerations. The situation as regards industrial wastes has been very ably summed up as follows:

The essential approach to the problem of ridding stream waters of undesirable industrial wastes lies in the active coöperation of the industries involved, always assuming, however, flexible and reasonably administered pollution legislation. The problem cannot be settled by abstract studies on the part of the government, nor by inflexible and arbitrary state or federal legislation. Waste materials are so diverse and complex that each industry and possibly each plant presents a special problem.³

There has been increasing evidence that various industries are recognizing the advantages of group action in solving some of their common problems of waste utilization or disposal, such as the employment of engineers especially for this purpose by the American Pulp and Paper Association and the American Petroleum Institute.

Interstate as well as intrastate pollution control problems have been given attention by states under informal agreements between various state health departments, legislative acts, or compacts (see Figure I), assisted by the U. S. Public Health Service and other

federal agencies. The trend in administration of stream pollution laws has been definitely toward development of comprehensive watershed clean-up programs, the effort being directed toward securing collective, cooperative action to reduce pollution to an unobjectionable minimum.

The indications are that the federal government will more definitely participate in pollution control activities in the future. This especially applies in regard to those problems involving interstate streams.

FEDERAL LEGISLATION DEVELOPMENTS

The past 4 years have seen much effort directed toward securing federal pollution legislation. Following the Dern-Lonergan conference of experts on stream pollution December 6, 1934, proceedings of which are set forth in *Senate Document #16*, 74th Congress, first session, enactment of adequate federal laws was advocated. It was recommended that proposed legislation embody these provisions:

1. Designate a federal agency to study and report on water pollution and pollution abatement projects.
2. Provide for loans and/or grants to public agencies, and loans to non-public agencies for pollution abatement works.
3. Provide that loans or grants be cleared with a water resources planning agency to insure reconciliation of pollution abatement work with the comprehensive utilization and control of water resources in the drainage areas affected.
5. Give congressional consent to negotiation of interstate compacts for pollution abatement.

A number of bills were introduced in the 74th Congress and gradually resolved through numerous hearings and conferences into the amended Barkley-Vinson bill that was passed in 1938 during the closing days of the 75th Congress. This bill was vetoed by the President on June 27, 1938, on the grounds that it

... provides for the direct presentation through the Secretary of the Treasury of the recommendations of the Surgeon General for the authorization by Congress of specific projects to be carried out under the loan or grant-in-aid provisions of the bill, without any opportunity for review by the Chief Executive. Thus the bill provides for the legislative assumption of responsibilities of the executive branch, and therefore, seems counter to the fundamental concept of our budget system that the planning of work programs in the executive agencies and their presentation to Congress in the form of estimates of appropriation is a duty imposed upon the Chief Executive and not one for exercise by the legislative branch.

It would appear that objections raised can be satisfactorily overcome in an amended bill during the next session of Congress. In the meantime, it is evident that further study is being given to federal pollution control legislation. In a recent announcement of a state division of the Izaak Walton League it was stated:

We expect to introduce a bill in the opening of the next Congress which will embrace the following essential provisions:

1. Additional study and research that may be needed and a clearing-house for dissemination of existing information on water pollution and its correction.
2. A definite provision that clean streams remain clean as a safeguard against the threat of additional or new pollution.
3. Adequate authority to administrative agency to enforce compliance with pollution abatement measures when necessary.

With much interest being shown it is likely that federal legislation will be forthcoming in the not distant future.

INTERSTATE COMPACTS

The first interstate compact for pollution control was developed by New York, New Jersey, and Connecticut and with Congressional approval became effective in 1936.⁴ The compact provides for the formation of an Interstate Sanitary District and the establishment of the Interstate Sanitary Commission, with the states pledging cooperation in the control of future pollution and in

abating existing pollution in the tidal and coastal waters in adjacent portions of the signatory states. Enactment of adequate legislation is agreed to by each state which will enable it to put and maintain the waters thereof in a satisfactory sanitary condition, and especially to protect the public health; to remove such pollution as becomes obnoxious or creates a nuisance; to prevent oil, grease, and solids from forming an offensive surface slick on the waters; and to prevent formation of sludge deposits along the shores or in the waterways. Authority is granted the commission, following suitable studies and hearings, to group the designated waters of the district into classes, and provide for standards of cleanliness for each class.

During June, 1938, a reciprocal agreement was entered into by New York, New Jersey, Pennsylvania, and Delaware. This agreement, proposed under the auspices of the Interstate Commission on the Delaware River Basin, was formally ratified and placed in effect by the Departments of Health of the 4 states. Minimum requirements covering sewage, industrial wastes, and other artificial polluting matter are specified.

In the Delaware River Basin, variable factors of location, size, character, flow, and varied uses of the stream has necessitated dividing it into 4 zones, with minimum requirements set up to meet the conditions in each zone. Under the provisions of the agreement all sewage, industrial waste, or other artificial polluting matter will need to be so treated as to produce effluents meeting the established minimum standards.

During October, 1938, the basis for an interstate compact in the Ohio River Basin was formulated, and recommendations were made for suitable legislation, to be enacted by the participating states. This action was taken by a delegation composed of 5 representatives from each state appointed by the

respective governors for this specific undertaking.

This Ohio River Valley Water Sanitation Compact pledges enactment by the individual states of any necessary legislation to place and maintain the waters of the drainage area in a satisfactory sanitary condition. It creates a "water sanitation district" comprising those portions of Illinois, Indiana, Kentucky, New York, Ohio, Pennsylvania, Tennessee, and West Virginia, within the Ohio River Drainage Basin, and establishes a non-paid commission composed of 3 representatives from each state and 3 representatives of the federal government. No single standard for the treatment of sewage and industrial wastes is recognized, but it was agreed that facilities provided for treatment of sewage should remove at least 45 per cent of the total suspended solids. The Commission is empowered to conduct a pollution survey of the district, and may issue orders after hearing requiring suitable treatment within a certain time limit. Costs are to be defrayed by the signatory states, respective amounts being computed, 50 per cent on population, and 50 per cent on area of each state within the district. The compact will become effective on ratification by the legislatures of a majority of the states involved.

CONCLUSION

In conclusion, there is definite evidence in recent developments of the widening scope of pollution control measures. Federal legislation very probably will be forthcoming during the next session of Congress. Further interstate compacts may be expected, with much activity in organizing the stream clean-up work under existing and pending compacts. Enlightened public opinion coupled with studies undertaken should also result in more adequate state legislation and support for pollution abatement programs.

This in brief is the present outlook for waterways pollution control.

Forms and Methods of Statistical Practice

Vital Statistics Section

THE Council of the Vital Statistics Section has, since the last Annual Meeting, referred to this committee two problems for investigation:

1. Formulating a standard procedure for interchange of provisional vital statistics between cities at the end of the year, to replace the present multiplicity of questionnaires
2. Revision of the Rules for Statistical Practice adopted by the Section some years ago, mainly at the 1908 and 1910 meetings

The committee held a meeting at Washington, D. C., August 2, 1938, to discuss both these subjects. Subsequently a letter and questionnaire were sent to the health officers of cities of 250,000 population and over, requesting suggestions and criticisms of a proposed standard report form. The response was very satisfactory. Twenty-six of the 36 city health officers replied, including those from the 14 largest cities and approximately half of the others. Following is a brief abstract of the questions and of the replies received:

Question 1. *Do you use or need provisional vital statistics data (births and deaths) from other cities before appearance of the printed reports?*

Twenty of the 26 health officers answering replied affirmatively, and only 2 in the negative. An even larger number agreed to use the standard report form, if adopted. Dr. Henry F. Vaughan of Detroit, and others, stressed the need of residence allocation at some length.

Dr. Philip Marks of Pittsburgh wrote: "The Department feels keenly the need of some standardization and will be most willing to coöperate in whatever plan is worked out by this committee."

Dr. George V. Truss of Birmingham, Ala., wrote: "The effort of the committee . . . will eliminate, as you say, 'a multiplicity of

questionnaires and reports.' We will be pleased to coöperate in this undertaking."

Dr. F. W. Peterson of Los Angeles stated that 35.5 per cent of the infant deaths of that city are nonresident, and about 22 per cent of the births and total deaths.

Dr. Adolph Weinziel of Portland, Oregon, wrote: "If you succeed in working this problem out, I am sure that all city health officers will be most grateful to you."

Question 2. *Please indicate whether the list of statistics shown on the attached form would be satisfactory for your purpose.*

In response to this question, various helpful suggestions were received, most of which have been incorporated in the model form accompanying this report.

Question 3. (a) *What estimated population are you now using? Total White Colored*

The purpose of this question was to determine whether it would not be possible to correct the misleading practice of comparing crude death rates of northern and southern cities, which differ widely as to color composition.

Question 3. (b) *Do you separate by color in your monthly tabulations of births and deaths so that provisional annual data by color could be made up from this source?*

All of the 26 cities except 3 replied that they routinely separated by color, and of these 3 (Philadelphia, Milwaukee, and Denver) only Philadelphia has more than 5 per cent colored.

Question 4. (a) *Do you receive from your State Health Department reports of your residents' born or dying in other parts of the state, or in other states?*

Only 7 of the 26 replying stated that they received such nonresident death reports from their State Health Departments; namely, New York City, Detroit, St. Louis, Baltimore,

MODEL FORM

Prepared by Committee on Forms and Methods of Statistical Practice, Vital Statistics
Section—American Public Health Association

Approved October 27, 1938, at Kansas City

Provisional Vital Statistics. City of, Year Ending Dec. 31, 19....
Corrected for residence: (a) Within State; (b) Interstate; (c) Not corrected
Estimated mid-year population, July 1, 19.... Total White Colored

Cause of Death with 1929 International List Number	Number of Deaths					
	Total	White	Colored			
All causes ^a						
Typhoid fever (1)						
Smallpox (6)						
Measles (7)						
Scarlet fever (8)						
Whooping cough (9)						
Diphtheria (10)						
Influenza (11)						
Poliomyelitis (16)						
Epidemic or lethargic encephalitis (17)						
Epidemic cerebrospinal meningitis (18)						
Pulmonary tuberculosis (23)						
Other forms of tuberculosis (24-32)						
Syphilis (34)						
Malaria (38)						
Rocky Mountain spotted fever (44c)						
Cancer, all forms (45-53)						
Diabetes mellitus (59)						
Pellagra (62)						
Progressive locomotor ataxia (80)						
Cerebral hem., emb., and throm. (82a, b)						
General paralysis of the insane (83)						
Diseases of the heart (90-95)						
Other circulatory diseases (96-103)						
Pneumonia, all forms (107-109)						
Diarrhea and enteritis under age 2 (119)						
Appendicitis (121)						
Nephritis, all forms (130-132)						
Diseases of puerperal state (140-150)						
Suicide (163-171)						
Homicide (172-175)						
All accidents (176-195) (201-214)						
Motor vehicle accidents (206, 208, 210, 211)						
Live Births ^a						
Stillbirths ^b						
Deaths under one year ^a						
Deaths under one month ^a						

^a Exclusive of stillbirths. ^b Minimum uterogestation included in stillbirths weeks.

Submitted by Title Date

Boston (from town clerks), Milwaukee, and Jersey City. Washington, D. C., receives reports from other states. Los Angeles, Birmingham, and possibly other cities are able to

make corrections within the county, thus eliminating a large part of the nonresident error. The great majority of the cities, however, do not receive the data necessary to

make residence-corrected tables with reasonable promptness.

Question 4. (b) *In which form are the nonresident records received?*

Seven cities receive transcripts and one (Detroit) photostatic copies of certificates. In Texas, New York, and apparently in other states, the cities receive residence-corrected tables when the final reports are issued by the State Health Department.

Question 4. (c) *Are the nonresident data received monthly, quarterly, or annually.*

In 6 cases the transcripts are received monthly; in 1 (Washington, D. C.) at irregular intervals; in the majority, not at all.

Question 4. (d) *Approximately when were nonresident data received for births and deaths of last December?*

Two cities, Milwaukee and Baltimore, received the data by the 10th of January; 3 in February; and 2 in March or later.

Question 4. (e) *If you now publish any tables corrected for residence, please describe or send specimens.*

Publication practice varies. A few cities apparently make only a one-way correction; that is, nonresident deaths occurring locally are deducted, but deaths of city residents occurring elsewhere are not added in.

Question 5. (a) *If a standard form for reporting provisional vital statistics is adopted, would you be willing to make up a table in such form, beginning in 1939? Monthly Quarterly Annually*

All of the cities replying indicated a willingness to make up provisional annual tables in the accepted standard form; but only half felt that quarterly or monthly reports were justified. Cleveland, Ohio, doubted the utility of *provisional* reports; and New York City advocated the distribution of final reports by cities, in addition to provisional, in order to promote more accurate comparisons.

Question 5. (b) *Would you favor publication of such data by governmental agencies, such as the Public*

Health Service or the Bureau of the Census?

Twenty-three of the 26 replying answered in the affirmative.

Question 5. (c) *Would you consider it desirable to distribute copies of the preliminary annual table to, say, the 30 largest cities as soon as the report is completed?*

Twenty-two answered in the affirmative. Some recommended that the reports be sent to the state health departments as well as to other cities.

RECOMMENDATIONS

In the light of the expressed desires of the city health officers consulted, your committee recommends:

1. That the proposed standard form for reporting provisional vital statistics, which is attached hereto as Exhibit 1, be adopted as standard by federal, state, and city health departments in requesting or preparing provisional vital statistics reports for cities.

2. That, in so far as is possible, state health departments provide cities with copies of nonresident records, preferably as transcripts, as soon after the close of each month as is practicable.

3. That all cities indicate on vital statistics tables whether the data are residence-corrected, residence correction being defined as including the necessary additive as well as deductive corrections. The committee recommends against the one-way correction; that is, against deductions without offsetting additions.

4. That published tables be color specific except where the proportion of non-whites is appreciably less than 5 per cent; and that the practice be avoided of comparing rates for northern and southern areas without color separation.

Residence Allocation

Vital Statistics Section

IN 1931 the Vital Statistics Section adopted a resolution requesting the U. S. Bureau of the Census to act as a clearing agency in an interstate transfer of copies of death certificates of nonresidents. The Bureau most willingly undertook this function, extending it the next year to include the transfer of copies of birth certificates. Within a very short time the interchange became practically country-wide; now only one state still remains outside this coöperative undertaking.

Several months ago the committee addressed a questionnaire to the registrars of all states and territories and the Dominion of Canada for the purpose of ascertaining:

1. How many states allocate births and deaths to place of residence, and what criteria are used in this allocation.

2. On what basis are the certificates of deaths of nonresidents selected for the interchange among states.

3. How promptly are transcripts sent to the Bureau of the Census.

4. What use is made by the states of the transcripts received from the Bureau of the Census.

5. What are the main difficulties encountered in connection with residence allocation.

The comprehensive replies from 34 states and the District of Columbia may be summarized as follows:

Birth and death records are allocated to some extent by most but not all of these states. In 7 states a nonresident is considered as a person who resided in a given area less than 1 year. The remaining states employ no time limit and use as a basis for the determination of residence the definition of the Bureau

of the Census, namely, "the usual place of abode."

The exceptions to these procedures relate principally to the following 4 types of death:

1. Deaths in custodial institutions—The Bureau of the Census considers the institution as the residence of its inmates, and in residence allocation includes the institutional deaths with those of the community in which the institution is located. Only 2 states follow this procedure; 5 states, while considering the institution the place of residence, keep the statistics of institutional mortality separate from those of the general population. Seventeen states allocate the institutional deaths to place of residence on admission, while 3 states allocate the deaths to whatever place is given on the certificate as the residence—the institution or the place of residence prior to admission.

2. Deaths of infants under 1 year—Most states allocate these deaths to the residence of the mother as given on the death certificate, but 3 states allocate them to the residence of the mother at the time the birth occurred, *i.e.*, to the place of residence as given on the birth certificate, and 2 to the place in which the birth was recorded.

3. Deaths from infectious diseases—The majority of states from which replies were received (18) allocate all deaths from infectious diseases to the place of usual residence, while 8 states allocate the deaths to the place where the disease originated if that fact can be determined.

4. Accidents—Five states allocate these deaths to place of residence; 7 to place of occurrence of the accident; 14 allocate the deaths both ways, making supplemental tabulations to show one or the other set of data.

Practically all states forward to the Bureau of the Census transcripts of all birth and death records on which the residence is given as "out of the State."

Most of the states are, however,

rather dilatory in forwarding the transcripts to the Bureau. At the time the committee's questionnaire was answered only 11 states had sent transcripts within 2 months after the receipt of the originals in the state office. In other words, by the end of June, these states had forwarded transcripts through the month of April. The latest transcripts sent by 8 states were for the month of March; in 11 states the transcripts were more than 3 months old; while 4 states had as yet sent no transcripts for the year 1938.

Of the 24 states which regularly tabulate resident figures, only 12 utilize the transcripts received through the Bureau of the Census from other states, while 2 states employ these transcripts for supplemental tabulations.

Ten states employ the transcripts for purposes other than residence tabulations. In most of these states the transcripts are consulted when a request for information discloses the fact that the required birth and death record is not on file in the state office. In one state the transcripts are used in the follow-up of cancer deaths; in another they are consulted by the inheritance tax section of the department of revenue, and in still another they are referred to by the motor vehicle bureau.

All of the replies received by the committee except one, from the state at present not coöperating, expressed full approval of the principle of the interstate exchange of transcripts of birth and death certificates. They all, either directly or by implication, indicated that the interchange was neither burdensome nor unproductive. It was felt generally, however, that to make the interchange of the utmost mutual benefit it was essential for all states to participate in it and that the transcripts be forwarded to the Bureau of the Census as promptly as possible. A number of states which at present make no use of these transcripts, informed

the committee that they would include them in their residence tabulations if they were received by April 1 following the year to which they relate.

Only one territory, Hawaii, replied to the questionnaire. Births and deaths occurring in the territory are allocated to place of residence, in general according to usual place of abode. Arrangement has recently been made with the U. S. Bureau of the Census for the interchange of nonresident transcripts, but it is doubtful if many certificates will be exchanged.

The Vital Statistics Branch of the Canadian Bureau of Statistics also allocates all births and deaths occurring within the dominion to place of residence.* The definition of residence employed is the usual place of abode, the only exception being for deaths in institutions for the insane, feeble-minded, and epileptic, which are transferred to the place of residence prior to admission wherever that can be obtained. The Dominion has entered into an agreement with the U. S. Bureau of the Census for an annual confidential exchange of transcripts of birth and death certificates of residents of the United States dying in Canada and residents of Canada dying in the United States, in order that each country might see how much its mortality rates are affected by such interchange.

To make possible a consistent allocation according to residence, it was felt that the items on the birth and death certificates relating to residence should be clarified in order to avoid the following common sources of confusion:

1. The residence as now given is usually the post office address, which is frequently different from the district of residence.
2. The expression "length of residence in place where death occurred" is frequently

* The American members of the committee wish to call attention to the excellent "Special Report on Deaths in Canada Classified According to Residence of Decedents, 1935," Ottawa, 1938.

confused with the length of residence in the place of usual abode.

3. It is impossible to ascertain the former residence of inmates of custodial institutions when the certificate clearly asks for usual place of abode, which is the institution.

The considered study of the problem of residence allocation leads the committee to make the following recommendations:

1. The items on the birth and death certificates which relate to residence should be rearranged and re-worded to eliminate ambiguity and to make possible unequivocal replies. The form of birth and death certificates used in New York State, for example, contains the question, "Is place of residence within the limits of a city or incorporated village?" The difficulty in connection with custodial institutions is resolved in the State of New Jersey by the addition, after "place of usual abode" of the statement "If an institution, place of residence prior to admission."

2. Interchange of transcripts of birth and death certificates should be expedited to make possible the greatest utilization of the information thus furnished to the states. Since most of the out of state births and deaths occur in adjacent states, it is possible that

some states would find it advantageous to arrange with all or some of the neighboring states for a direct interchange of transcripts of birth and death certificates of nonresidents. Such an interchange would make possible the utilization of the nonresident data in the computation of monthly rates, while the final annual tabulations could include also the transcripts from non-adjacent states routed through the Bureau of the Census. In sending transcripts to the Bureau, each state would note the number of transcripts, if any, sent directly to other states.

3. Interstate transfer should include all transcripts which will be subject to allocation according to the broadest interpretation of the term residence. While this would lead to some states receiving transcripts, which according to their rules would not be considered as those of residents, it would at the same time provide other states which employ a more general interpretation of the term, with the information they wish to have.
